

## 7.E: Exercises

1.	<p>Arrange the following compounds in the order of the increasing polarity of their bonds: CO, HF, NaCl, O<sub>2</sub></p>
2.	<p>Pauling introduced the idea of defining the percent ionic character possessed by a chemical bond. A covalent bond with equal sharing of the charge density has 0% ionic character, and a perfect ionic bond would of course have 100% ionic character. One method of estimating the percent ionic character is to set it equal to the ratio of the observed dipole moment to the value of <math>eR</math>, all multiplied by 100.</p> $\text{percent ionic character} = \left( \frac{\mu}{eR} \right) 100$ <p>The value of <math>eR</math> is, it will be recalled, the value of the dipole moment when one charge is completely transferred in the formation of the bond and the resulting ions are spherical.</p> <p>Use this method to determine the percent ionic character of the bonds in the diatomic hydrides, LiH to HF. Could any real molecule ever exhibit 100% ionic character according to this definition?</p>
3.	<p>Pauling has proposed an empirical relationship which relates the percent ionic character in a bond to the electronegativity difference.</p> $\text{percent ionic character} = \left( 1 - e^{-\frac{1}{4}(\chi_A - \chi_B)^2} \right) 100$ <p>From the electronegativity values given in <a href="#">Table 7-2</a>, it is seen that the difference (<math>\chi_F - \chi_H</math>) is greater than the value (<math>\chi_H - \chi_{Li}</math>). Using the above relationship, we can calculate that the bond in HF should be 59% ionic while that in LiH should be only 26% ionic. Does the estimate of the relative ionic character in HF and LiH based on the electronegativity difference agree with that obtained by a comparison of the molecular charge density and density difference maps for these two molecules?</p>
