

## 27.1: Definition of Euler Angles

The rotational motion of a rigid body is completely defined by tracking the set of principal axes ( $x_1, x_2, x_3$ ), with origin at the center of mass, as they turn relative to a set of fixed axes ( $X, Y, Z$ ). The principal axes can be completely defined relative to the fixed set by three angles: the two angles  $(\theta, \phi)$  fix the direction of  $x_3$ , but that leaves the pair  $x_1, x_2$  free to turn in the plane perpendicular to  $x_3$ , the angle  $\psi$  fixes their orientation.

Figure 27.1.1:  $\theta, \phi$  follow standard physics practice for labeling the direction of body axis  $x_3$  relative to lab axes  $X, Y, Z$ ,  $\psi$  is the body rotation angle from  $ON$  to the  $x_1$  axis in the  $x_1, x_2$  plane, about its  $x_3$  axis.

To see these angles, start with the fixed axes, draw a circle centered at the origin in the horizontal  $X, Y$  plane. Now draw a circle of the same size, also centered at the same origin, but in the principal axes  $x_1, x_2$  plane. Landau calls the line of intersection of these circles (or discs) the *line of nodes*. It goes through the common origin, and is a diameter of both circles.

The angle between these two planes, which is also the angle between  $Z, x_3$  (since they're the perpendiculars to the planes) is labeled  $\theta$ .

The angle between this line of nodes and the  $X$  axis is  $\phi$ . It should be clear that  $\theta, \phi$  together fix the direction of  $x_3$ , then the other axes are fixed by giving  $\psi$ , the angle between  $x_1$  and the line of nodes  $ON$ . The direction of measurement of  $\phi, \psi$  around  $Z, x_3$  are given by the right-hand or corkscrew rule.
