

Book: Probability, Mathematical Statistics,
Stochastic Processes

This text is disseminated via the Open Education Resource (OER) LibreTexts Project (<https://LibreTexts.org>) and like the hundreds of other texts available within this powerful platform, it is freely available for reading, printing and "consuming." Most, but not all, pages in the library have licenses that may allow individuals to make changes, save, and print this book. Carefully consult the applicable license(s) before pursuing such effects.

Instructors can adopt existing LibreTexts texts or Remix them to quickly build course-specific resources to meet the needs of their students. Unlike traditional textbooks, LibreTexts' web based origins allow powerful integration of advanced features and new technologies to support learning.

The LibreTexts mission is to unite students, faculty and scholars in a cooperative effort to develop an easy-to-use online platform for the construction, customization, and dissemination of OER content to reduce the burdens of unreasonable textbook costs to our students and society. The LibreTexts project is a multi-institutional collaborative venture to develop the next generation of open-access texts to improve postsecondary education at all levels of higher learning by developing an Open Access Resource environment. The project currently consists of 14 independently operating and interconnected libraries that are constantly being optimized by students, faculty, and outside experts to supplant conventional paper-based books. These free textbook alternatives are organized within a central environment that is both vertically (from advance to basic level) and horizontally (across different fields) integrated.

The LibreTexts libraries are Powered by [NICE CXOne](#) and are supported by the Department of Education Open Textbook Pilot Project, the UC Davis Office of the Provost, the UC Davis Library, the California State University Affordable Learning Solutions Program, and Merlot. This material is based upon work supported by the National Science Foundation under Grant No. 1246120, 1525057, and 1413739.

Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation nor the US Department of Education.

Have questions or comments? For information about adoptions or adaptations contact info@LibreTexts.org. More information on our activities can be found via Facebook (<https://facebook.com/Libretexts>), Twitter (<https://twitter.com/libretexts>), or our blog (<http://Blog.Libretexts.org>).

Sources and Resources

1: Foundations

- 1.1: Sets
- 1.2: Functions
- 1.3: Relations
- 1.4: Partial Orders
- 1.5: Equivalence Relations
- 1.6: Cardinality
- 1.7: Counting Measure
- 1.8: Combinatorial Structures
- 1.9: Topological Spaces
- 1.10: Metric Spaces
- 1.11: Measurable Spaces
- 1.12: Special Set Structures

2: Probability Spaces

- 2.1: Random Experiments
- 2.2: Events and Random Variables
- 2.3: Probability Measures
- 2.4: Conditional Probability
- 2.5: Independence
- 2.6: Convergence
- 2.7: Measure Spaces
- 2.8: Existence and Uniqueness
- 2.9: Probability Spaces Revisited
- 2.10: Stochastic Processes
- 2.11: Filtrations and Stopping Times

3: Distributions

- 3.1: Discrete Distributions
- 3.2: Continuous Distributions
- 3.3: Mixed Distributions
- 3.4: Joint Distributions
- 3.5: Conditional Distributions
- 3.6: Distribution and Quantile Functions
- 3.7: Transformations of Random Variables
- 3.8: Convergence in Distribution
- 3.9: General Distribution Functions

- 3.10: The Integral With Respect to a Measure
- 3.11: Properties of the Integral
- 3.12: General Measures
- 3.13: Absolute Continuity and Density Functions
- 3.14: Function Spaces

4: Expected Value

- 4.1: Definitions and Basic Properties
- 4.2: Additional Properties
- 4.3: Variance
- 4.4: Skewness and Kurtosis
- 4.5: Covariance and Correlation
- 4.6: Generating Functions
- 4.7: Conditional Expected Value
- 4.8: Expected Value and Covariance Matrices
- 4.9: Expected Value as an Integral
- 4.10: Conditional Expected Value Revisited
- 4.11: Vector Spaces of Random Variables
- 4.12: Uniformly Integrable Variables
- 4.13: Kernels and Operators

5: Special Distributions

- 5.1: Location-Scale Families
- 5.2: General Exponential Families
- 5.3: Stable Distributions
- 5.4: Infinitely Divisible Distributions
- 5.5: Power Series Distributions
- 5.6: The Normal Distribution
- 5.7: The Multivariate Normal Distribution
- 5.8: The Gamma Distribution
- 5.9: Chi-Square and Related Distribution
- 5.10: The Student t Distribution
- 5.11: The F Distribution
- 5.12: The Lognormal Distribution
- 5.13: The Folded Normal Distribution
- 5.14: The Rayleigh Distribution
- 5.15: The Maxwell Distribution
- 5.16: The Lévy Distribution
- 5.17: The Beta Distribution
- 5.18: The Beta Prime Distribution
- 5.19: The Arcsine Distribution
- 5.20: General Uniform Distributions
- 5.21: The Uniform Distribution on an Interval
- 5.22: Discrete Uniform Distributions
- 5.23: The Semicircle Distribution
- 5.24: The Triangle Distribution
- 5.25: The Irwin-Hall Distribution
- 5.26: The U-Power Distribution
- 5.27: The Sine Distribution
- 5.28: The Laplace Distribution
- 5.29: The Logistic Distribution

- 5.30: The Extreme Value Distribution
- 5.31: The Hyperbolic Secant Distribution
- 5.32: The Cauchy Distribution
- 5.33: The Exponential-Logarithmic Distribution
- 5.34: The Gompertz Distribution
- 5.35: The Log-Logistic Distribution
- 5.36: The Pareto Distribution
- 5.37: The Wald Distribution
- 5.38: The Weibull Distribution
- 5.39: Benford's Law
- 5.40: The Zeta Distribution
- 5.41: The Logarithmic Series Distribution

6: Random Samples

- 6.1: Introduction
- 6.2: The Sample Mean
- 6.3: The Law of Large Numbers
- 6.4: The Central Limit Theorem
- 6.5: The Sample Variance
- 6.6: Order Statistics
- 6.7: Sample Correlation and Regression
- 6.8: Special Properties of Normal Samples

7: Point Estimation

- 7.1: Estimators
- 7.2: The Method of Moments
- 7.3: Maximum Likelihood
- 7.4: Bayesian Estimation
- 7.5: Best Unbiased Estimators
- 7.6: Sufficient, Complete and Ancillary Statistics

8: Set Estimation

- 8.1: Introduction to Set Estimation
- 8.2: Estimation the Normal Model
- 8.3: Estimation in the Bernoulli Model
- 8.4: Estimation in the Two-Sample Normal Model
- 8.5: Bayesian Set Estimation

9: Hypothesis Testing

- 9.1: Introduction to Hypothesis Testing
- 9.2: Tests in the Normal Model
- 9.3: Tests in the Bernoulli Model
- 9.4: Tests in the Two-Sample Normal Model
- 9.5: Likelihood Ratio Tests
- 9.6: Chi-Square Tests

10: Geometric Models

- 10.1: Buffon's Problems
- 10.2: Bertrand's Paradox
- 10.3: Random Triangles

11: Bernoulli Trials

- 11.1: Introduction to Bernoulli Trials
- 11.2: The Binomial Distribution
- 11.3: The Geometric Distribution
- 11.4: The Negative Binomial Distribution
- 11.5: The Multinomial Distribution
- 11.6: The Simple Random Walk
- 11.7: The Beta-Bernoulli Process

12: Finite Sampling Models

- 12.1: Introduction to Finite Sampling Models
- 12.2: The Hypergeometric Distribution
- 12.3: The Multivariate Hypergeometric Distribution
- 12.4: Order Statistics
- 12.5: The Matching Problem
- 12.6: The Birthday Problem
- 12.7: The Coupon Collector Problem
- 12.8: Pólya's Urn Process
- 12.9: The Secretary Problem

13: Games of Chance

- 13.1: Introduction to Games of Chance
- 13.2: Poker
- 13.3: Simple Dice Games
- 13.4: Craps
- 13.5: Roulette
- 13.6: The Monty Hall Problem
- 13.7: Lotteries
- 13.8: The Red and Black Game
- 13.9: Timid Play
- 13.10: Bold Play
- 13.11: Optimal Strategies

14: The Poisson Process

- 14.1: Introduction to the Poisson Process
- 14.2: The Exponential Distribution
- 14.3: The Gamma Distribution
- 14.4: The Poisson Distribution
- 14.5: Thinning and Superposition
- 14.6: Non-homogeneous Poisson Processes
- 14.7: Compound Poisson Processes
- 14.8: Poisson Processes on General Spaces

15: Renewal Processes

- 15.1: Introduction
- 15.2: Renewal Equations
- 15.3: Renewal Limit Theorems
- 15.4: Delayed Renewal Processes
- 15.5: Alternating Renewal Processes
- 15.6: Renewal Reward Processes

16: Markov Processes

- 16.1: Introduction to Markov Processes
- 16.2: Potentials and Generators for General Markov Processes
- 16.3: Introduction to Discrete-Time Chains
- 16.4: Transience and Recurrence for Discrete-Time Chains
- 16.5: Periodicity of Discrete-Time Chains
- 16.6: Stationary and Limiting Distributions of Discrete-Time Chains
- 16.7: Time Reversal in Discrete-Time Chains
- 16.8: The Ehrenfest Chains
- 16.9: The Bernoulli-Laplace Chain
- 16.10: Discrete-Time Reliability Chains
- 16.11: Discrete-Time Branching Chain
- 16.12: Discrete-Time Queuing Chains
- 16.13: Discrete-Time Birth-Death Chains
- 16.14: Random Walks on Graphs
- 16.15: Introduction to Continuous-Time Markov Chains
- 16.16: Transition Matrices and Generators of Continuous-Time Chains
- 16.17: Potential Matrices
- 16.18: Stationary and Limiting Distributions of Continuous-Time Chains
- 16.19: Time Reversal in Continuous-Time Chains
- 16.20: Chains Subordinate to the Poisson Process
- 16.21: Continuous-Time Birth-Death Chains
- 16.22: Continuous-Time Queuing Chains
- 16.23: Continuous-Time Branching Chains

17: Martingales

- 17.1: Introduction to Martingales
- 17.2: Properties and Constructions
- 17.3: Stopping Times
- 17.4: Inequalities
- 17.5: Convergence
- 17.6: Backwards Martingales

18: Brownian Motion

- 18.1: Standard Brownian Motion
- 18.2: Brownian Motion with Drift and Scaling
- 18.3: The Brownian Bridge
- 18.4: Geometric Brownian Motion

CHAPTER OVERVIEW

1: Foundations

In this chapter we review several mathematical topics that form the foundation of probability and mathematical statistics. These include the algebra of sets and functions, general relations with special emphasis on equivalence relations and partial orders, counting measure, and some basic combinatorial structures such as permutations and combinations. We also discuss some advanced topics from topology and measure theory. You may wish to review the topics in this chapter as the need arises.

This page titled [1: Foundations](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

1.1: Sets

Set theory is the foundation of probability and statistics, as it is for almost every branch of mathematics.

Sets and subsets

In this text, sets and their elements are primitive, self-evident concepts, an approach that is sometimes referred to as *naive set theory*.

A *set* is simply a collection of objects; the objects are referred to as *elements* of the set. The statement that x is an element of set S is written $x \in S$, and the negation that x is not an element of S is written as $x \notin S$. By definition, a set is completely determined by its elements; thus sets A and B are *equal* if they have the same elements:

$$A = B \text{ if and only if } x \in A \iff x \in B \quad (1.1.1)$$

Our next definition is the subset relation, another very basic concept.

If A and B are sets then A is a *subset* of B if every element of A is also an element of B :

$$A \subseteq B \text{ if and only if } x \in A \implies x \in B \quad (1.1.2)$$

Concepts in set theory are often illustrated with small, schematic sketches known as *Venn diagrams*, named for John Venn. The Venn diagram in the picture below illustrates the subset relation.

Figure 1.1.1: $A \subseteq B$

As noted earlier, membership is a primitive, undefined concept in naive set theory. However, the following construction, known as *Russell's paradox*, after the mathematician and philosopher Bertrand Russell, shows that we cannot be too cavalier in the construction of sets.

Let R be the set of all sets A such that $A \notin A$. Then $R \in R$ if and only if $R \notin R$.

Proof

The contradiction follows from the definition of R : If $R \in R$, then by definition, $R \notin R$. If $R \notin R$, then by definition, $R \in R$. The net result, of course, is that R is not a well-defined set.

Usually, the sets under discussion in a particular context are all subsets of a well-defined, specified set S , often called a *universal set*. The use of a universal set prevents the type of problem that arises in Russell's paradox. That is, if S is a given set and $p(x)$ is a *predicate* on S (that is, a valid mathematical statement that is either true or false for each $x \in S$), then $\{x \in S : p(x)\}$ is a valid subset of S . Defining a set in this way is known as *predicate form*. The other basic way to define a set is simply by listing its elements; this method is known as *list form*.

In contrast to a universal set, the *empty set*, denoted \emptyset , is the set with no elements.

$\emptyset \subseteq A$ for every set A .

Proof

$\emptyset \subseteq A$ means that $x \in \emptyset \implies x \in A$. Since the premise is false, the implication is true.

One step up from the empty set is a set with just one element. Such a set is called a *singleton set*. The subset relation is a partial order on the collection of subsets of S .

Suppose that A , B and C are subsets of a set S . Then

1. $A \subseteq A$ (the *reflexive property*).
2. If $A \subseteq B$ and $B \subseteq A$ then $A = B$ (the *anti-symmetric property*).
3. If $A \subseteq B$ and $B \subseteq C$ then $A \subseteq C$ (the *transitive property*).

Here are a couple of variations on the subset relation.

Suppose that A and B are sets.

1. If $A \subseteq B$ and $A \neq B$, then A is a *strict subset* of B and we sometimes write $A \subset B$.
2. If $\emptyset \subset A \subset B$, then A is called a *proper subset* of B .

The collection of all subsets of a given set frequently plays an important role, particularly when the given set is the universal set.

If S is a set, then the set of all subsets of S is known as the *power set* of S and is denoted $\mathcal{P}(S)$.

Special Sets

The following special sets are used throughout this text. Defining them will also give us practice using list and predicate form.

Special Sets

1. \mathbb{R} denotes the set of *real numbers* and is the universal set for the other subsets in this list.
2. $\mathbb{N} = \{0, 1, 2, \dots\}$ is the set of *natural numbers*
3. $\mathbb{N}_+ = \{1, 2, 3, \dots\}$ is the set of *positive integers*
4. $\mathbb{Z} = \{\dots, -2, -1, 0, 1, 2, \dots\}$ is the set of *integers*
5. $\mathbb{Q} = \{m/n : m \in \mathbb{Z} \text{ and } n \in \mathbb{N}_+\}$ is the set of *rational numbers*
6. $\mathbb{A} = \{x \in \mathbb{R} : p(x) = 0 \text{ for some polynomial } p \text{ with integer coefficients}\}$ is the set of *algebraic numbers*.

Note that $\mathbb{N}_+ \subset \mathbb{N} \subset \mathbb{Z} \subset \mathbb{Q} \subset \mathbb{A} \subset \mathbb{R}$. We will also occasionally need the set of *complex numbers* $\mathbb{C} = \{x + iy : x, y \in \mathbb{R}\}$ where i is the imaginary unit. The following special rational numbers turn out to be useful for various constructions.

For $n \in \mathbb{N}$, a rational number of the form $j/2^n$ where $j \in \mathbb{Z}$ is odd is a *dyadic rational* (or *binary rational*) of rank n .

1. For $n \in \mathbb{N}$, the set of dyadic rationals of rank n or less is $\mathbb{D}_n = \{j/2^n : j \in \mathbb{Z}\}$.
2. The set of all dyadic rationals is $\mathbb{D} = \{j/2^n : j \in \mathbb{Z} \text{ and } n \in \mathbb{N}\}$.

Note that $\mathbb{D}_0 = \mathbb{Z}$ and $\mathbb{D}_n \subset \mathbb{D}_{n+1}$ for $n \in \mathbb{N}$, and of course, $\mathbb{D} \subset \mathbb{Q}$. We use the usual notation for *intervals* of real numbers, but again the definitions provide practice with predicate notation.

Suppose that $a, b \in \mathbb{R}$ with $a < b$.

1. $[a, b] = \{x \in \mathbb{R} : a \leq x \leq b\}$. This interval is *closed*.
2. $(a, b) = \{x \in \mathbb{R} : a < x < b\}$. This interval is *open*.
3. $[a, b) = \{x \in \mathbb{R} : a \leq x < b\}$. This interval is *closed-open*.
4. $(a, b] = \{x \in \mathbb{R} : a < x \leq b\}$. This interval is *open-closed*.

The terms *open* and *closed* are actually topological concepts.

You may recall that $x \in \mathbb{R}$ is rational if and only if the decimal expansion of x either terminates or forms a repeating block. The binary rationals have simple binary expansions (that is, expansions in the base 2 number system).

A number $x \in \mathbb{R}$ is a binary rational of rank $n \in \mathbb{N}_+$ if and only if the binary expansion of x is finite, with 1 in position n (after the separator).

Proof

It suffices to consider $x \in (0, 1)$. The result is very simple so we just give the first few cases.

1. The number with rank 1 is $1/2$ with binary expansion 0.1
2. The numbers with rank 2 are $1/4$ with expansion 0.01 and $3/4$ with expansion 0.11
3. The numbers with rank 3 are $1/8$ with expansion 0.001, $3/8$ with expansion 0.011, $5/8$ with expansion 0.101, and $7/8$ with expansion 0.111.

Set Operations

We are now ready to review the basic operations of set theory. For the following definitions, suppose that A and B are subsets of a universal set, which we will denote by S .

The *union* of A and B is the set obtained by combining the elements of A and B .

$$A \cup B = \{x \in S : x \in A \text{ or } x \in B\} \quad (1.1.3)$$

The *intersection* of A and B is the set of elements common to both A and B :

$$A \cap B = \{x \in S : x \in A \text{ and } x \in B\} \quad (1.1.4)$$

If $A \cap B = \emptyset$ then A and B are *disjoint*.

So A and B are disjoint if the two sets have no elements in common.

The *set difference* of B and A is the set of elements that are in B but not in A :

$$B \setminus A = \{x \in S : x \in B \text{ and } x \notin A\} \quad (1.1.5)$$

Sometimes (particularly in older works and particularly when $A \subseteq B$), the notation $B - A$ is used instead of $B \setminus A$. When $A \subseteq B$, $B - A$ is known as *proper set difference*.

The *complement* of A is the set of elements that are *not* in A :

$$A^c = \{x \in S : x \notin A\} \quad (1.1.6)$$

Note that union, intersection, and difference are *binary* set operations, while complement is a *unary* set operation.

In the Venn diagram app, select each of the following and note the shaded area in the diagram.

1. A
2. B
3. A^c
4. B^c
5. $A \cup B$
6. $A \cap B$

Basic Rules

In the following theorems, A , B , and C are subsets of a universal set S . The proofs are straightforward, and just use the definitions and basic logic. Try the proofs yourself before reading the ones in the text.

$$A \cap B \subseteq A \subseteq A \cup B.$$

The *identity laws*:

1. $A \cup \emptyset = A$
2. $A \cap S = A$

So the empty set acts as an identity relative to the union operation, and the universal set acts as an identity relative to the intersection operation.

The *idempotent laws*:

1. $A \cup A = A$
2. $A \cap A = A$

The *complement laws*:

1. $A \cup A^c = S$
2. $A \cap A^c = \emptyset$

The *double complement law*: $(A^c)^c = A$

The *commutative laws*:

1. $A \cup B = B \cup A$
2. $A \cap B = B \cap A$

Proof

These results follow from the commutativity of the *or* and *and* logical operators.

The *associative laws*:

1. $A \cup (B \cup C) = (A \cup B) \cup C$
2. $A \cap (B \cap C) = (A \cap B) \cap C$

Proof

These results follow from the associativity of the *or* and *and* logical operators.

Thus, we can write $A \cup B \cup C$ without ambiguity. Note that x is an element of this set if and only if x is an element of at least one of the three given sets. Similarly, we can write $A \cap B \cap C$ without ambiguity. Note that x is an element of this set if and only if x is an element of all three of the given sets.

The *distributive laws*:

1. $A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$
2. $A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$

Proof

1. $x \in A \cap (B \cup C)$ if and only if $x \in A$ and $x \in B \cup C$ if and only if $x \in A$ and either $x \in B$ or $x \in C$ if and only if $x \in A$ and $x \in B$, or, $x \in A$ and $x \in C$ if and only if $x \in A \cap B$ or $x \in A \cap C$ if and only if $x \in (A \cap B) \cup (A \cap C)$.
2. The proof is exactly the same as (a), but with *or* and *and* interchanged.

So intersection distributes over union, and union distributes over intersection. It's interesting to compare the distributive properties of set theory with those of the real number system. If $x, y, z \in \mathbb{R}$, then $x(y+z) = (xy) + (xz)$, so multiplication distributes over addition, but it is *not true* that $x + (yz) = (x+y)(x+z)$, so addition does not distribute over multiplication. The following results are particularly important in probability theory.

DeMorgan's laws (named after Augustus DeMorgan):

1. $(A \cup B)^c = A^c \cap B^c$
2. $(A \cap B)^c = A^c \cup B^c$.

Proof

1. $x \in (A \cup B)^c$ if and only if $x \notin A \cup B$ if and only if $x \notin A$ and $x \notin B$ if and only if $x \in A^c$ and $x \in B^c$ if and only if $x \in A^c \cap B^c$
2. $x \in (A \cap B)^c$ if and only if $x \notin A \cap B$ if and only if $x \notin A$ or $x \notin B$ if and only if $x \in A^c$ or $x \in B^c$ if and only if $x \in A^c \cup B^c$

The following result explores the connections between the subset relation and the set operations.

The following statements are equivalent:

1. $A \subseteq B$
2. $B^c \subseteq A^c$
3. $A \cup B = B$
4. $A \cap B = A$
5. $A \setminus B = \emptyset$

Proof

1. Recall that $A \subseteq B$ means that $x \in A \implies x \in B$.
2. $B^c \subseteq A^c$ means that $x \notin B \implies x \notin A$. This is the contrapositive of (a) and hence is equivalent to (a).
3. If $A \subseteq B$ then clearly $A \cup B = B$. Conversely suppose $A \cup B = B$. If $x \in A$ then $x \in A \cup B$ so $x \in B$. Hence $A \subseteq B$.
4. If $A \subseteq B$ then clearly $A \cap B = A$. Conversely suppose $A \cap B = A$. If $x \in A$ then $x \in A \cap B$ and so $x \in B$. Hence $A \subseteq B$.
5. Suppose $A \subseteq B$. If $x \in A$ then $x \in B$ and so by definition, $x \notin A \setminus B$. If $x \notin A$ then again by definition, $x \notin A \setminus B$. Thus $A \setminus B = \emptyset$. Conversely suppose that $A \setminus B = \emptyset$. If $x \in A$ then $x \notin A \setminus B$ so $x \in B$. Thus $A \subseteq B$.

In addition to the [special sets](#) defined earlier, we also have the following:

More special sets

1. $\mathbb{R} \setminus \mathbb{Q}$ is the set of *irrational numbers*
2. $\mathbb{R} \setminus \mathbb{A}$ is the set of *transcendental numbers*

Since $\mathbb{Q} \subset \mathbb{A} \subset \mathbb{R}$ it follows that $\mathbb{R} \setminus \mathbb{A} \subset \mathbb{R} \setminus \mathbb{Q}$, that is, every transcendental number is also irrational.

Set difference can be expressed in terms of complement and intersection. *All* of the other set operations (complement, union, and intersection) can be expressed in terms of difference.

Results for set difference:

1. $B \setminus A = B \cap A^c$
2. $A^c = S \setminus A$
3. $A \cap B = A \setminus (A \setminus B)$
4. $A \cup B = S \setminus \{(S \setminus A) \setminus [(S \setminus A) \setminus (S \setminus B)]\}$

Proof

1. This is clear from the definition: $B \setminus A = B \cap A^c = \{x \in S : x \in B \text{ and } x \notin A\}$.
2. This follows from (a) with $B = S$.
3. Using (a), DeMorgan's law, and the distributive law, the right side is

$$A \cap (A \cap B^c)^c = A \cap (A^c \cup B) = (A \cap A^c) \cup (A \cap B) = \emptyset \cup (A \cap B) = A \cap B \quad (1.1.7)$$

4. Using (a), (b), DeMorgan's law, and the distributive law, the right side is

$$[A^c \cap (A^c \cap B)^c]^c = A \cup (A^c \cap B) = (A \cup A^c) \cap (A \cup B) = S \cap (A \cup B) = A \cup B \quad (1.1.8)$$

So in principle, we could do all of set theory using the one operation of set difference. But as (c) and (d) suggest, the results would be hideous.

$$(A \cup B) \setminus (A \cap B) = (A \setminus B) \cup (B \setminus A) \quad .$$

Proof

A direct proof is simple, but for practice let's give a proof using set algebra, in particular, DeMorgan's law, and the distributive law:

$$(A \cup B) \setminus (A \cap B) = (A \cup B) \cap (A \cap B)^c = (A \cup B) \cap (A^c \cup B^c) \quad (1.1.9)$$

$$= (A \cap A^c) \cup (B \cap A^c) \cup (A \cap B^c) \cup (B \cap B^c) \quad (1.1.10)$$

$$= \emptyset \cup (B \setminus A) \cup (A \setminus B) \cup \emptyset = (A \setminus B) \cup (B \setminus A) \quad (1.1.11)$$

The set in the previous result is called the *symmetric difference* of A and B , and is sometimes denoted $A \triangle B$. The elements of this set belong to one but not both of the given sets. Thus, the symmetric difference corresponds to *exclusive or* in the same way that union corresponds to *inclusive or*. That is, $x \in A \cup B$ if and only if $x \in A$ or $x \in B$ (or both); $x \in A \triangle B$ if and only if $x \in A$ or $x \in B$, but not both. On the other hand, the complement of the symmetric difference consists of the elements that belong to both or neither of the given sets:

$$(A \triangle B)^c = (A \cap B) \cup (A^c \cap B^c) = (A^c \cup B) \cap (B^c \cup A)$$

Proof

Again, a direct proof is simple, but let's give an algebraic proof for practice:

$$(A \triangle B)^c = [(A \cup B) \cap (A \cap B)^c]^c \quad (1.1.12)$$

$$= (A \cup B)^c \cup (A \cap B) = (A^c \cap B^c) \cup (A \cap B) \quad (1.1.13)$$

$$= (A^c \cup A) \cap (A^c \cup B) \cap (B^c \cup A) \cap (B^c \cup B) \quad (1.1.14)$$

$$= S \cap (A^c \cup B) \cap (B^c \cup A) \cap S = (A^c \cup B) \cap (B^c \cup A) \quad (1.1.15)$$

There are 16 different (in general) sets that can be constructed from two given events A and B .

Proof

S is the union of 4 pairwise disjoint sets: $A \cap B$, $A \cap B^c$, $A^c \cap B$, and $A^c \cap B^c$. If A and B are in “general position”, these 4 sets are distinct. Every set that can be constructed from A and B is a union of some (perhaps none, perhaps all) of these 4 sets. There are $2^4 = 16$ sub-collections of the 4 sets.

Open the Venn diagram app. This app lists the 16 sets that can be constructed from given sets A and B using the set operations.

1. Select each of the four subsets in the proof of the last exercise: $A \cap B$, $A \cap B^c$, $A^c \cap B$, and $A^c \cap B^c$. Note that these are disjoint and their union is S .
2. Select each of the other 12 sets and show how each is a union of some of the sets in (a).

General Operations

The operations of union and intersection can easily be extended to a finite or even an infinite collection of sets.

Definitions

Suppose that \mathcal{A} is a nonempty collection of subsets of a universal set S . In some cases, the subsets in \mathcal{A} may be naturally *indexed* by a nonempty index set I , so that $\mathcal{A} = \{A_i : i \in I\}$. (In a technical sense, any collection of subsets can be indexed.)

The *union* of the collection of sets \mathcal{A} is the set obtained by combining the elements of the sets in \mathcal{A} :

$$\bigcup \mathcal{A} = \{x \in S : x \in A \text{ for some } A \in \mathcal{A}\} \quad (1.1.16)$$

If $\mathcal{A} = \{A_i : i \in I\}$, so that the collection of sets is indexed, then we use the more natural notation:

$$\bigcup_{i \in I} A_i = \{x \in S : x \in A_i \text{ for some } i \in I\} \quad (1.1.17)$$

The *intersection* of the collection of sets \mathcal{A} is the set of elements common to all of the sets in \mathcal{A} :

$$\bigcap \mathcal{A} = \{x \in S : x \in A \text{ for all } A \in \mathcal{A}\} \quad (1.1.18)$$

If $\mathcal{A} = \{A_i : i \in I\}$, so that the collection of sets is indexed, then we use the more natural notation:

$$\bigcap_{i \in I} A_i = \{x \in S : x \in A_i \text{ for all } i \in I\} \quad (1.1.19)$$

Often the index set is an “integer interval” of \mathbb{N} . In such cases, an even more natural notation is to use the upper and lower limits of the index set. For example, if the collection is $\{A_i : i \in \mathbb{N}_+\}$ then we would write $\bigcup_{i=1}^{\infty} A_i$ for the union and $\bigcap_{i=1}^{\infty} A_i$ for the intersection. Similarly, if the collection is $\{A_i : i \in \{1, 2, \dots, n\}\}$ for some $n \in \mathbb{N}_+$, we would write $\bigcup_{i=1}^n A_i$ for the union and $\bigcap_{i=1}^n A_i$ for the intersection.

A collection of sets \mathcal{A} is *pairwise disjoint* if the intersection of any two sets in the collection is empty: $A \cap B = \emptyset$ for every $A, B \in \mathcal{A}$ with $A \neq B$.

A collection of sets \mathcal{A} is said to *partition* a set B if the collection \mathcal{A} is pairwise disjoint and $\bigcup \mathcal{A} = B$.

Partitions are intimately related to equivalence relations. As an example, for $n \in \mathbb{N}$, the set

$$\mathcal{D}_n = \left\{ \left[\frac{j}{2^n}, \frac{j+1}{2^n} \right) : j \in \mathbb{Z} \right\} \quad (1.1.20)$$

is a partition of \mathbb{R} into intervals of equal length $1/2^n$. Note that the endpoints are the [dyadic rationals](#) of rank n or less, and that \mathcal{D}_{n+1} can be obtained from \mathcal{D}_n by dividing each interval into two equal parts. This sequence of partitions is one of the reasons that the dyadic rationals are important.

Basic Rules

In the following problems, $\mathcal{A} = \{A_i : i \in I\}$ is a collection of subsets of a universal set S , indexed by a nonempty set I , and B is a subset of S .

The general *distributive laws*:

1. $(\bigcup_{i \in I} A_i) \cap B = \bigcup_{i \in I} (A_i \cap B)$
2. $(\bigcap_{i \in I} A_i) \cup B = \bigcap_{i \in I} (A_i \cup B)$

Restate the laws in the notation where the collection \mathcal{A} is not indexed.

Proof

1. x is an element of the set on the left or the right of the equation if and only if $x \in B$ and $x \in A_i$ for some $i \in I$.
2. x is an element of the set on the left or the right of the equation if and only if $x \in B$ or $x \in A_i$ for every $i \in I$.

$$(\bigcup \mathcal{A}) \cap B = \bigcup \{A \cap B : A \in \mathcal{A}\}, (\bigcap \mathcal{A}) \cup B = \bigcap \{A \cup B : A \in \mathcal{A}\}$$

The general *De Morgan's laws*:

1. $(\bigcup_{i \in I} A_i)^c = \bigcap_{i \in I} A_i^c$
2. $(\bigcap_{i \in I} A_i)^c = \bigcup_{i \in I} A_i^c$

Restate the laws in the notation where the collection \mathcal{A} is not indexed.

Proof

1. $x \in (\bigcup_{i \in I} A_i)^c$ if and only if $x \notin \bigcup_{i \in I} A_i$ if and only if $x \notin A_i$ for every $i \in I$ if and only if $x \in A_i^c$ for every $i \in I$ if and only if $x \in \bigcap_{i \in I} A_i^c$.
2. $x \in (\bigcap_{i \in I} A_i)^c$ if and only if $x \notin \bigcap_{i \in I} A_i$ if and only if $x \notin A_i$ for some $i \in I$ if and only if $x \in A_i^c$ for some $i \in I$ if and only if $x \in \bigcup_{i \in I} A_i^c$.

$$(\bigcup \mathcal{A})^c = \bigcap \{A^c : A \in \mathcal{A}\}, (\bigcap \mathcal{A})^c = \bigcup \{A^c : A \in \mathcal{A}\}$$

Suppose that the collection \mathcal{A} partitions S . For any subset B , the collection $\{A \cap B : A \in \mathcal{A}\}$ partitions B .

Proof

Suppose $\mathcal{A} = \{A_i : i \in I\}$ where I is an index set. If $i, j \in I$ with $i \neq j$ then $(A_i \cap B) \cap (A_j \cap B) = (A_i \cap A_j) \cap B = \emptyset \cap B = \emptyset$, so the collection $\{A_i \cap B : i \in I\}$ is disjoint. Moreover, by the distributive law,

$$\bigcup_{i \in I} (A_i \cap B) = \left(\bigcup_{i \in I} A_i \right) \cap B = S \cap B = B \quad (1.1.21)$$

Figure 1.1.2: A partition of S induces a partition of B

Suppose that $\{A_i : i \in \mathbb{N}_+\}$ is a collection of subsets of a universal set S

1. $\bigcap_{n=1}^{\infty} \bigcup_{k=n}^{\infty} A_k = \{x \in S : x \in A_k \text{ for infinitely many } k \in \mathbb{N}_+\}$
2. $\bigcup_{n=1}^{\infty} \bigcap_{k=n}^{\infty} A_k = \{x \in S : x \in A_k \text{ for all but finitely many } k \in \mathbb{N}_+\}$

Proof

1. Note that $x \in \bigcap_{n=1}^{\infty} \bigcup_{k=n}^{\infty} A_k$ if and only if for every $n \in \mathbb{N}_+$ there exists $k \geq n$ such that $x \in A_k$. In turn, this occurs if and only if $x \in A_k$ for infinitely many $k \in \mathbb{N}_+$.
2. Note that $x \in \bigcup_{n=1}^{\infty} \bigcap_{k=n}^{\infty} A_k$ if and only if there exists $n \in \mathbb{N}_+$ such that $x \in A_k$ for every $k \geq n$. In turn, this occurs if and only if $x \in A_k$ for all but finitely many $k \in \mathbb{N}_+$.

The sets in the previous result turn out to be important in the study of probability.

Product sets

Definitions

Product sets are sets of *sequences*. The defining property of a sequence, of course, is that *order* as well as *membership* is important.

Let us start with *ordered pairs*. In this case, the defining property is that $(a, b) = (c, d)$ if and only if $a = c$ and $b = d$. Interestingly, the structure of an ordered pair can be defined just using set theory. The construction in the result below is due to Kazimierz Kuratowski

Define $(a, b) = \{\{a\}, \{a, b\}\}$. This definition captures the defining property of an ordered pair.

Proof

Suppose that $(a, b) = (c, d)$ so that $\{\{a\}, \{a, b\}\} = \{\{c\}, \{c, d\}\}$. In the case that $a = b$ note that $(a, b) = \{\{a\}\}$. Thus we must have $\{c\} = \{c, d\} = \{a\}$ and hence $c = d = a$, and in particular, $a = c$ and $b = d$. In the case that $a \neq b$, we must have $\{c\} = \{a\}$ and hence $c = a$. But we cannot have $\{c, d\} = \{a\}$ because then $(c, d) = \{\{a\}\}$ and hence $\{a, b\} = \{a\}$, which would force $a = b$, a contradiction. Thus we must have $\{c, d\} = \{a, b\}$. Since $c = a$ and $a \neq b$ we must have $d = b$. The converse is trivial: if $a = c$ and $b = d$ then $\{a\} = \{c\}$ and $\{a, b\} = \{c, d\}$ so $(a, b) = (c, d)$.

Of course, it's important not to confuse the ordered pair (a, b) with the open interval (a, b) , since the same notation is used for both. Usually it's clear from context which type of object is referred to. For *ordered triples*, the defining property is $(a, b, c) = (d, e, f)$ if and only if $a = d$, $b = e$, and $c = f$. Ordered triples can be defined in terms of ordered pairs, which via the last result, uses only set theory.

Define $(a, b, c) = (a, (b, c))$. This definition captures the defining property of an ordered triple.

Proof

Suppose $(a, b, c) = (d, e, f)$. Then $(a, (b, c)) = (d, (e, f))$. Hence by the definition of an ordered pair, we must have $a = d$ and $(b, c) = (e, f)$. Using the definition again we have $b = e$ and $c = f$. Conversely, if $a = d$, $b = e$, and $c = f$, then $(b, c) = (e, f)$ and hence $(a, (b, c)) = (d, (e, f))$. Thus $(a, b, c) = (d, e, f)$.

All of this is just to show how complicated structures can be built from simpler ones, and ultimately from set theory. But enough of that! More generally, two ordered sequences of the same size (finite or infinite) are the same if and only if their corresponding coordinates agree. Thus for $n \in \mathbb{N}_+$, the definition for n -tuples is $(x_1, x_2, \dots, x_n) = (y_1, y_2, \dots, y_n)$ if and only if $x_i = y_i$ for all $i \in \{1, 2, \dots, n\}$. For infinite sequences, $(x_1, x_2, \dots) = (y_1, y_2, \dots)$ if and only if $x_i = y_i$ for all $i \in \mathbb{N}_+$.

Suppose now that we have a sequence of n sets, (S_1, S_2, \dots, S_n) , where $n \in \mathbb{N}_+$. The *Cartesian product* of the sets is defined as follows:

$$S_1 \times S_2 \times \cdots \times S_n = \{(x_1, x_2, \dots, x_n) : x_i \in S_i \text{ for } i \in \{1, 2, \dots, n\}\} \quad (1.1.22)$$

Cartesian products are named for René Descartes. If $S_i = S$ for each i , then the Cartesian product set can be written compactly as S^n , a *Cartesian power*. In particular, recall that \mathbb{R} denotes the set of real numbers so that \mathbb{R}^n is n -dimensional *Euclidean space*, named after Euclid, of course. The elements of $\{0, 1\}^n$ are called *bit strings* of length n . As the name suggests, we sometimes represent elements of this product set as strings rather than sequences (that is, we omit the parentheses and commas). Since the coordinates just take two values, there is no risk of confusion.

Suppose that we have an infinite sequence of sets (S_1, S_2, \dots) . The *Cartesian product* of the sets is defined by

$$S_1 \times S_2 \times \cdots = \{(x_1, x_2, \dots) : x_i \in S_i \text{ for each } i \in \{1, 2, \dots\}\} \quad (1.1.23)$$

When $S_i = S$ for $i \in \mathbb{N}_+$, the Cartesian product set is sometimes written as a Cartesian power as S^∞ or as $S^{\mathbb{N}_+}$. An explanation for the last notation, as well as a much more general construction for products of sets, is given in the next section on functions. Also, notation similar to that of general union and intersection is often used for Cartesian product, with \prod as the operator. So

$$\prod_{i=1}^n S_i = S_1 \times S_2 \times \cdots \times S_n, \quad \prod_{i=1}^{\infty} S_i = S_1 \times S_2 \times \cdots \quad (1.1.24)$$

Rules for Product Sets

We will now see how the set operations relate to the Cartesian product operation. Suppose that S and T are sets and that $A \subseteq S$, $B \subseteq S$ and $C \subseteq T$, $D \subseteq T$. The sets in the theorems below are subsets of $S \times T$.

The most important rules that relate Cartesian product with union, intersection, and difference are the *distributive rules*:

Distributive rules for product sets

1. $A \times (C \cup D) = (A \times C) \cup (A \times D)$
2. $(A \cup B) \times C = (A \times C) \cup (B \times C)$
3. $A \times (C \cap D) = (A \times C) \cap (A \times D)$
4. $(A \cap B) \times C = (A \times C) \cap (B \times C)$
5. $A \times (C \setminus D) = (A \times C) \setminus (A \times D)$
6. $(A \setminus B) \times C = (A \times C) \setminus (B \times C)$

Proof

1. $(x, y) \in A \times (C \cup D)$ if and only if $x \in A$ and $y \in C \cup D$ if and only if $x \in A$ and either $y \in C$ or $y \in D$ if and only if $x \in A$ and $y \in C$, or $x \in A$ and $y \in D$ if and only if $(x, y) \in A \times C$ or $(x, y) \in A \times D$ if and only if $(x, y) \in (A \times C) \cup (A \times D)$.
2. Similar to (a), but with the roles of the coordinates reversed.
3. $(x, y) \in A \times (C \cap D)$ if and only if $x \in A$ and $y \in C \cap D$ if and only if $x \in A$ and $y \in C$ and $y \in D$ if and only if $(x, y) \in A \times C$ and $(x, y) \in A \times D$ if and only if $(x, y) \in (A \times C) \cap (A \times D)$.
4. Similar to (c) but with the roles of the coordinates reversed.
5. $(x, y) \in A \times (C \setminus D)$ if and only if $x \in A$ and $y \in C \setminus D$ if and only if $x \in A$ and $y \in C$ and $y \notin D$ if and only if $(x, y) \in A \times C$ and $(x, y) \notin A \times D$ if and only if $(x, y) \in (A \times C) \setminus (A \times D)$.
6. Similar to (e) but with the roles of the coordinates reversed.

In general, the product of unions is larger than the corresponding union of products.

$$(A \cup B) \times (C \cup D) = (A \times C) \cup (A \times D) \cup (B \times C) \cup (B \times D)$$

Proof

$(x, y) \in (A \cup B) \times (C \cup D)$ if and only if $x \in A \cup B$ and $y \in C \cup D$ if and only if at least one of the following is true: $x \in A$ and $y \in C$, $x \in A$ and $y \in D$, $x \in B$ and $y \in C$, $x \in B$ and $y \in D$ if and only if $(x, y) \in (A \times C) \cup (A \times D) \cup (B \times C) \cup (B \times D)$

So in particular it follows that $(A \times C) \cup (B \times D) \subseteq (A \cup B) \times (C \cup D)$. On the other hand, the product of intersections is the same as the corresponding intersection of products.

$$(A \times C) \cap (B \times D) = (A \cap B) \times (C \cap D)$$

Proof

$(x, y) \in (A \times C) \cap (B \times D)$ if and only if $(x, y) \in A \times C$ and $(x, y) \in B \times D$ if and only if $x \in A$ and $y \in C$ and $x \in B$ and $y \in D$ if and only if $x \in A \cap B$ and $y \in C \cap D$ if and only if $(x, y) \in (A \cap B) \times (C \cap D)$.

In general, the product of differences is smaller than the corresponding difference of products.

$$(A \setminus B) \times (C \setminus D) = [(A \times C) \setminus (A \times D)] \setminus [(B \times C) \setminus (B \times D)]$$

Proof

$(x, y) \in (A \setminus B) \times (C \setminus D)$ if and only if $x \in A \setminus B$ and $y \in C \setminus D$ if and only if $x \in A$ and $x \notin B$ and $y \in C$ and $y \notin D$. On the other hand, $(x, y) \in [(A \times C) \setminus (A \times D)] \setminus [(B \times C) \setminus (B \times D)]$ if and only if $(x, y) \in (A \times C) \setminus (A \times D)$ and $(x, y) \notin (B \times C) \setminus (B \times D)$. The first statement means that $x \in A$ and $y \in C$ and $y \notin D$. The second statement is the negation of $x \in B$ and $y \in C$ and $y \notin D$. The two statements both hold if and only if $x \in A$ and $x \notin B$ and $y \in C$ and $y \notin D$.

So in particular it follows that $(A \setminus B) \times (C \setminus D) \subseteq (A \times C) \setminus (B \times D)$.

Projections and Cross Sections

In this discussion, suppose again that S and T are nonempty sets, and that $C \subseteq S \times T$.

Cross Sections

1. The cross section of C in the first coordinate at $x \in S$ is $C_x = \{y \in T : (x, y) \in C\}$
2. The cross section of C at in the second coordinate at $y \in T$ is

$$C^y = \{x \in S : (x, y) \in C\} \quad (1.1.25)$$

Note that $C_x \subseteq T$ for $x \in S$ and $C^y \subseteq S$ for $y \in T$.

Projections

1. The projection of C onto T is $C_T = \{y \in T : (x, y) \in C \text{ for some } x \in S\}$.
2. The projection of C onto S is $C^S = \{x \in S : (x, y) \in C \text{ for some } y \in T\}$.

The projections are the unions of the appropriate cross sections.

Unions

1. $C_T = \bigcup_{x \in S} C_x$
2. $C^S = \bigcup_{y \in T} C^y$

Cross sections are preserved under the set operations. We state the result for cross sections at $x \in S$. By symmetry, of course, analogous results hold for cross sections at $y \in T$.

Suppose that $C, D \subseteq S \times T$. Then for $x \in S$,

1. $(C \cup D)_x = C_x \cup D_x$
2. $(C \cap D)_x = C_x \cap D_x$
3. $(C \setminus D)_x = C_x \setminus D_x$

Proof

1. $y \in (C \cup D)_x$ if and only if $(x, y) \in C \cup D$ if and only if $(x, y) \in C$ or $(x, y) \in D$ if and only if $y \in C_x$ or $y \in D_x$.
2. The proof is just like (a), with *and* replacing *or*.
3. The proof is just like (a), with *and not* replacing *or*.

For projections, the results are a bit more complicated. We give the results for projections onto T ; naturally the results for projections onto S are analogous.

Suppose again that $C, D \subseteq S \times T$. Then

1. $(C \cup D)_T = C_T \cup D_T$
2. $(C \cap D)_T \subseteq C_T \cap D_T$
3. $(C_T)^c \subseteq (C^c)_T$

Proof

1. Suppose that $y \in (C \cup D)_T$. Then there exists $x \in S$ such that $(x, y) \in C \cup D$. Hence $(x, y) \in C$ so $y \in C_T$, or $(x, y) \in D$ so $y \in D_T$. In either case, $y \in C_T \cup D_T$. Conversely, suppose that $y \in C_T \cup D_T$. Then $y \in C_T$ or $y \in D_T$. If $y \in C_T$ then there exists $x \in S$ such that $(x, y) \in C$. But then $(x, y) \in C \cup D$ so $y \in (C \cup D)_T$. Similarly if $y \in D_T$ then $y \in (C \cup D)_T$.
2. Suppose that $y \in (C \cap D)_T$. Then there exists $x \in S$ such that $(x, y) \in C \cap D$. Hence $(x, y) \in C$ so $y \in C_T$ and $(x, y) \in D$ so $y \in D_T$. Therefore $y \in C_T \cap D_T$.
3. Suppose that $y \in (C_T)^c$. Then $y \notin C_T$, so for every $x \in S$, $(x, y) \notin C$. Fix $x_0 \in S$. Then $(x_0, y) \notin C$ so $(x_0, y) \in C^c$ and therefore $y \in (C^c)_T$.

It's easy to see that equality does not hold in general in parts (b) and (c). In part (b) for example, suppose that $A_1, A_2 \subseteq S$ are nonempty and disjoint and $B \subseteq T$ is nonempty. Let $C = A_1 \times B$ and $D = A_2 \times B$. Then $C \cap D = \emptyset$ so $(C \cap D)_T = \emptyset$. But $C_T = D_T = B$. In part (c) for example, suppose that A is a nonempty proper subset of S and B is a nonempty proper subset of T . Let $C = A \times B$. Then $C_T = B$ so $(C_T)^c = B^c$. On the other hand, $C^c = (A^c \times B) \cup (A \times B^c) \cup (A^c \times B^c)$, so $(C^c)_T = T$.

Cross sections and projections will be extended to very general product sets in the next section on Functions.

Computational Exercises

Subsets of \mathbb{R}

The universal set is $[0, \infty)$. Let $A = [0, 5]$ and $B = (3, 7)$. Express each of the following in terms of intervals:

1. $A \cap B$
2. $A \cup B$
3. $A \setminus B$
4. $B \setminus A$
5. A^c

Answer

1. $(3, 5]$
2. $[0, 7)$
3. $[0, 3]$
4. $(5, 7)$
5. $(5, \infty)$

The universal set is \mathbb{N} . Let $A = \{n \in \mathbb{N} : n \text{ is even}\}$ and let $B = \{n \in \mathbb{N} : n \leq 9\}$. Give each of the following:

1. $A \cap B$ in list form

2. $A \cup B$ in predicate form
3. $A \setminus B$ in list form
4. $B \setminus A$ in list form
5. A^c in predicate form
6. B^c in list form

Answer

1. $\{0, 2, 4, 6, 8\}$
2. $\{n \in \mathbb{N} : n \text{ is even or } n \leq 9\}$
3. $\{10, 12, 14, \dots\}$
4. $\{1, 3, 5, 7, 9\}$
5. $\{n \in \mathbb{N} : n \text{ is odd}\}$
6. $\{10, 11, 12, \dots\}$

Coins and Dice

Let $S = \{1, 2, 3, 4\} \times \{1, 2, 3, 4, 5, 6\}$. This is the set of outcomes when a 4-sided die and a 6-sided die are tossed. Further let $A = \{(x, y) \in S : x = 2\}$ and $B = \{(x, y) \in S : x + y = 7\}$. Give each of the following sets in list form:

1. A
2. B
3. $A \cap B$
4. $A \cup B$
5. $A \setminus B$
6. $B \setminus A$

Answer

1. $\{(2, 1), (2, 2), (2, 3), (2, 4), (2, 5), (2, 6)\}$
2. $\{(1, 6), (2, 5), (3, 4), (4, 3)\}$
3. $\{(2, 5)\}$
4. $\{(2, 1), (2, 2), (2, 3), (2, 4), (2, 5), (2, 6), (1, 6), (3, 4), (4, 3)\}$
5. $\{(2, 1), (2, 2), (2, 3), (2, 4), (2, 6)\}$
6. $\{(1, 6), (3, 4), (4, 3)\}$

Let $S = \{0, 1\}^3$. This is the set of outcomes when a coin is tossed 3 times (0 denotes tails and 1 denotes heads). Further let $A = \{(x_1, x_2, x_3) \in S : x_2 = 1\}$ and $B = \{(x_1, x_2, x_3) \in S : x_1 + x_2 + x_3 = 2\}$. Give each of the following sets in list form, using bit-string notation:

1. S
2. A
3. B
4. A^c
5. B^c
6. $A \cap B$
7. $A \cup B$
8. $A \setminus B$
9. $B \setminus A$

Answer

1. $\{000, 100, 010, 001, 110, 101, 011, 111\}$
2. $\{010, 110, 011, 111\}$
3. $\{110, 011, 101\}$
4. $\{000, 100, 001, 101\}$
5. $\{000, 100, 010, 001, 111\}$
6. $\{110, 011\}$
7. $\{010, 110, 011, 111, 101\}$
8. $\{010, 111\}$
9. $\{101\}$

Let $S = \{0, 1\}^2$. This is the set of outcomes when a coin is tossed twice (0 denotes tails and 1 denotes heads). Give $\mathcal{P}(S)$ in list form.

Answer

$\{\emptyset, \{00\}, \{01\}, \{10\}, \{11\}, \{00, 01\}, \{00, 10\}, \{00, 11\}, \{01, 10\}, \{01, 11\}, \{10, 11\}, \{00, 01, 10\}, \{00, 01, 11\}, \{00, 10, 11\}, \{01, 10, 11\}, \{00, 01, 10, 11\}\}$

Cards

A standard *card deck* can be modeled by the Cartesian product set

$$D = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, j, q, k\} \times \{\clubsuit, \diamondsuit, \heartsuit, \spadesuit\} \quad (1.1.26)$$

where the first coordinate encodes the *denomination* or *kind* (ace, 2–10, jack, queen, king) and where the second coordinate encodes the *suit* (clubs, diamonds, hearts, spades). Sometimes we represent a card as a *string* rather than an ordered pair (for example $q\heartsuit$ for the queen of hearts). For the problems in this subsection, the card deck D is the universal set.

Let H denote the set of hearts and F the set of face cards. Find each of the following:

1. $H \cap F$
2. $H \setminus F$
3. $F \setminus H$
4. $H \triangle F$

Answer

1. $\{j\heartsuit, q\heartsuit, k\heartsuit\}$
2. $\{1\heartsuit, 2\heartsuit, 3\heartsuit, 4\heartsuit, 5\heartsuit, 6\heartsuit, 7\heartsuit, 8\heartsuit, 9\heartsuit, 10\heartsuit\}$
3. $\{j\clubsuit, q\clubsuit, k\clubsuit, j\diamondsuit, q\diamondsuit, k\diamondsuit, j\spadesuit, q\spadesuit, k\spadesuit\}$
4. $\{1\heartsuit, 2\heartsuit, 3\heartsuit, 4\heartsuit, 5\heartsuit, 6\heartsuit, 7\heartsuit, 8\heartsuit, 9\heartsuit, 10\heartsuit, j\clubsuit, q\clubsuit, k\clubsuit, j\diamondsuit, q\diamondsuit, k\diamondsuit, j\spadesuit, q\spadesuit, k\spadesuit\}$

A *bridge hand* is a subset of D with 13 cards. Often bridge hands are described by giving the cross sections by suit.

Suppose that N is a bridge hand, held by a player named North, defined by

$$N^\clubsuit = \{2, 5, q\}, N^\diamondsuit = \{1, 5, 8, q, k\}, N^\heartsuit = \{8, 10, j, q\}, N^\spadesuit = \{1\} \quad (1.1.27)$$

Find each of the following:

1. The nonempty cross sections of N by denomination.
2. The projection of N onto the set of suits.
3. The projection of N onto the set of denominations

Answer

1. $N_1 = \{\diamondsuit, \spadesuit\}, N_2 = \{\clubsuit\}, N_5 = \{\clubsuit, \diamondsuit\}, N_8 = \{\diamondsuit, \heartsuit\}, N_{10} = \{\heartsuit\}, N_j = \{\heartsuit\}, N_q = \{\clubsuit, \diamondsuit, \heartsuit\}, N_k = \{\diamondsuit\}$
2. $\{\clubsuit, \diamondsuit, \heartsuit, \spadesuit\}$
3. $\{1, 2, 5, 8, 10, j, q, k\}$

By contrast, it is usually more useful to describe a *poker hand* by giving the cross sections by denomination. In the usual version of *draw poker*, a hand is a subset of D with 5 cards.

Suppose that B is a poker hand, held by a player named Bill, with

$$B_1 = \{\clubsuit, \spadesuit\}, B_8 = \{\clubsuit, \spadesuit\}, B_q = \{\heartsuit\} \quad (1.1.28)$$

Find each of the following:

1. The nonempty cross sections of B by suit.
2. The projection of B onto the set of suits.
3. The projection of B onto the set of denominations

Answer

1. $B^\clubsuit = \{1, 8\}, B^\heartsuit = \{q\}, B^\spadesuit = \{1, 8\}$
2. $\{\clubsuit, \heartsuit, \spadesuit\}$
3. $\{1, 8, q\}$

The poker hand in the last exercise is known as a *dead man's hand*. Legend has it that Wild Bill Hickock held this hand at the time of his murder in 1876.

General unions and intersections

For the problems in this subsection, the universal set is \mathbb{R} .

Let $A_n = [0, 1 - \frac{1}{n}]$ for $n \in \mathbb{N}_+$. Find

1. $\bigcap_{n=1}^{\infty} A_n$
2. $\bigcup_{n=1}^{\infty} A_n$
3. $\bigcap_{n=1}^{\infty} A_n^c$

4. $\bigcup_{n=1}^{\infty} A_n^c$

Answer

1. $\{0\}$
2. $[0, 1)$
3. $(-\infty, 0) \cup [1, \infty)$
4. $\mathbb{R} - \{0\}$

Let $A_n = (2 - \frac{1}{n}, 5 + \frac{1}{n})$ for $n \in \mathbb{N}_+$. Find

1. $\bigcap_{n=1}^{\infty} A_n$
2. $\bigcup_{n=1}^{\infty} A_n$
3. $\bigcap_{n=1}^{\infty} A_n^c$
4. $\bigcup_{n=1}^{\infty} A_n^c$

Answer

1. $[2, 5]$
2. $(1, 6)$
3. $(-\infty, 1] \cup [6, \infty)$
4. $(-\infty, 2) \cup (5, \infty)$

Subsets of \mathbb{R}^2

Let T be the closed triangular region in \mathbb{R}^2 with vertices $(0, 0)$, $(1, 0)$, and $(1, 1)$. Find each of the following:

1. The cross section T_x for $x \in \mathbb{R}$
2. The cross section T^y for $y \in \mathbb{R}$
3. The projection of T onto the horizontal axis
4. The projection of T onto the vertical axis

Answer

1. $T_x = [0, x]$ for $x \in [0, 1]$, $T_x = \emptyset$ otherwise
2. $T^y = [y, 1]$ for $y \in [0, 1]$, $T^y = \emptyset$ otherwise
3. $[0, 1]$
4. $[0, 1]$

1.2: Functions

Functions play a central role in probability and statistics, as they do in every other branch of mathematics. For the most part, the proofs in this section are straightforward, so be sure to try them yourself before reading the ones in the text.

Definitions and Properties

Basic Definitions

We start with the formal, technical definition of a function. It's not very intuitive, but has the advantage that it only requires set theory.

A function f from a set S into a set T is a subset of the product set $S \times T$ with the property that for each element $x \in S$, there exists a unique element $y \in T$ such that $(x, y) \in f$. If f is a function from S to T we write $f : S \rightarrow T$. If $(x, y) \in f$ we write $y = f(x)$.

Less formally, a function f from S into T is a “rule” (or “procedure” or “algorithm”) that assigns to each $x \in S$ a unique element $f(x) \in T$. The definition of a function as a set of ordered pairs, is due to Kazimierz Kuratowski. The term *map* or *mapping* is also used in place of function, so we could say that f maps S into T .

Figure 1.2.1: A function f from S into T

The sets S and T in the definition are clearly important.

Suppose that $f : S \rightarrow T$.

1. The set S is the *domain* of f .
2. The set T is the *range space* or *co-domain* of f .
3. The *range* of f is the set of function values. That is, $\text{range}(f) = \{y \in T : y = f(x) \text{ for some } x \in S\}$.

The domain and range are completely specified by a function. That's not true of the co-domain: if f is a function from S into T , and U is another set with $T \subseteq U$, then we can also think of f as a function from S into U . The following definitions are natural and important.

Suppose again that $f : S \rightarrow T$.

1. f maps S *onto* T if $\text{range}(f) = T$. That is, for each $y \in T$ there exists $x \in S$ such that $f(x) = y$.
2. f is *one-to-one* if distinct elements in the domain are mapped to distinct elements in the range. That is, if $u, v \in S$ and $u \neq v$ then $f(u) \neq f(v)$.

Clearly a function always maps its domain onto its range. Note also that f is one-to-one if $f(u) = f(v)$ implies $u = v$ for $u, v \in S$.

Inverse functions

A function that is one-to-one and onto can be “reversed” in a sense.

If f maps S one-to-one onto T , the *inverse* of f is the function f^{-1} from T onto S given by

$$f^{-1}(y) = x \iff f(x) = y; \quad x \in S, y \in T \quad (1.2.1)$$

If you like to think of a function as a set of ordered pairs, then $f^{-1} = \{(y, x) \in T \times S : (x, y) \in f\}$. The fact that f is one-to-one and onto ensures that f^{-1} is a valid function from T onto S . Sets S and T are in *one-to-one correspondence* if there exists a one-to-one function from S onto T . One-to-one correspondence plays an essential role in the study of cardinality.

Restrictions

The domain of a function can be *restricted* to create a new function.

Suppose that $f : S \rightarrow T$ and that $A \subseteq S$. The function $f_A : A \rightarrow T$ defined by $f_A(x) = f(x)$ for $x \in A$ is the *restriction of f to A* .

As a set of ordered pairs, note that $f_A = \{(x, y) \in f : x \in A\}$.

Composition

Composition is perhaps the most important way to combine two functions to create another function.

Suppose that $g : R \rightarrow S$ and $f : S \rightarrow T$. The *composition* of f with g is the function $f \circ g : R \rightarrow T$ defined by

$$(f \circ g)(x) = f(g(x)), \quad x \in R \quad (1.2.2)$$

Composition is *associative*:

Suppose that $h : R \rightarrow S$, $g : S \rightarrow T$, and $f : T \rightarrow U$. Then

$$f \circ (g \circ h) = (f \circ g) \circ h \quad (1.2.3)$$

Proof

Note that both functions map R into U . Using the definition of composition, the value of both functions at $x \in R$ is $f(g(h(x)))$.

Thus we can write $f \circ g \circ h$ without ambiguity. On the other hand, composition is not *commutative*. Indeed depending on the domains and co-domains, $f \circ g$ might be defined when $g \circ f$ is not. Even when both are defined, they may have different domains and co-domains, and so of course cannot be the same function. Even when both are defined and have the same domains and co-domains, the two compositions will not be the same in general. Examples of all of these cases are given in the computational exercises below.

Suppose that $g : R \rightarrow S$ and $f : S \rightarrow T$.

1. If f and g are one-to-one then $f \circ g$ is one-to-one.
2. If f and g are onto then $f \circ g$ is onto.

Proof

1. Suppose that $u, v \in R$ and $(f \circ g)(u) = (f \circ g)(v)$. Then $f(g(u)) = f(g(v))$. Since f is one-to-one, $g(u) = g(v)$. Since g is one-to-one, $u = v$.
2. Suppose that $z \in T$. Since f is onto, there exist $y \in S$ with $f(y) = z$. Since g is onto, there exists $x \in R$ with $g(x) = y$. Then $(f \circ g)(x) = f(g(x)) = f(y) = z$.

The *identity function* on a set S is the function I_S from S onto S defined by $I_S(x) = x$ for $x \in S$

The identity function acts like an identity with respect to the operation of composition.

If $f : S \rightarrow T$ then

1. $f \circ I_S = f$
2. $I_T \circ f = f$

Proof

1. Note that $f \circ I_S : S \rightarrow T$. For $x \in S$, $(f \circ I_S)(x) = f(I_S(x)) = f(x)$.
2. Note that $I_T \circ f : S \rightarrow T$. For $x \in S$, $(I_T \circ f)(x) = I_T(f(x)) = f(x)$.

The inverse of a function is really the inverse with respect to composition.

Suppose that f is a one-to-one function from S onto T . Then

1. $f^{-1} \circ f = I_S$
2. $f \circ f^{-1} = I_T$

Proof

1. Note that $f^{-1} \circ f : S \rightarrow S$. For $x \in S$, $(f^{-1} \circ f)(x) = f^{-1}(f(x)) = x$.
2. Note that $f \circ f^{-1} : T \rightarrow T$. For $y \in T$, $(f \circ f^{-1})(y) = f(f^{-1}(y)) = y$.

An element $x \in S^n$ can be thought of as a function from $\{1, 2, \dots, n\}$ into S . Similarly, an element $x \in S^\infty$ can be thought of as a function from \mathbb{N}_+ into S . For such a sequence x , of course, we usually write x_i instead of $x(i)$. More generally, if S and T are sets, then the set of all functions from S into T is denoted by T^S . In particular, as we noted in the last section, S^∞ is also (and more accurately) written as $S^{\mathbb{N}_+}$.

Suppose that g is a one-to-one function from R onto S and that f is a one-to-one function from S onto T . Then $(f \circ g)^{-1} = g^{-1} \circ f^{-1}$.

Proof

Note that $(f \circ g)^{-1} : T \rightarrow R$ and $g^{-1} \circ f^{-1} : T \rightarrow R$. For $y \in T$, let $x = (f \circ g)^{-1}(y)$. Then $(f \circ g)(x) = y$ so that $f(g(x)) = y$ and hence $g(x) = f^{-1}(y)$ and finally $x = g^{-1}(f^{-1}(y))$.

Inverse Images

Inverse images of a function play a fundamental role in probability, particularly in the context of random variables.

Suppose that $f : S \rightarrow T$. If $A \subseteq T$, the *inverse image* of A under f is the subset of S given by

$$f^{-1}(A) = \{x \in S : f(x) \in A\} \quad (1.2.4)$$

So $f^{-1}(A)$ is the subset of S consisting of those elements that map into A .

Figure 1.2.2: The inverse image of A under f

Technically, the inverse images define a new function from $\mathcal{P}(T)$ into $\mathcal{P}(S)$. We use the same notation as for the *inverse function*, which is defined when f is one-to-one and onto. These are very different functions, but usually no confusion results. The following important theorem shows that inverse images preserve all set operations.

Suppose that $f : S \rightarrow T$, and that $A, B \subseteq T$. Then

1. $f^{-1}(A \cup B) = f^{-1}(A) \cup f^{-1}(B)$
2. $f^{-1}(A \cap B) = f^{-1}(A) \cap f^{-1}(B)$
3. $f^{-1}(A \setminus B) = f^{-1}(A) \setminus f^{-1}(B)$
4. If $A \subseteq B$ then $f^{-1}(A) \subseteq f^{-1}(B)$
5. If A and B are disjoint, so are $f^{-1}(A)$ and $f^{-1}(B)$

Proof

1. $x \in f^{-1}(A \cup B)$ if and only if $f(x) \in A \cup B$ if and only if $f(x) \in A$ or $f(x) \in B$ if and only if $x \in f^{-1}(A)$ or $x \in f^{-1}(B)$ if and only if $x \in f^{-1}(A) \cup f^{-1}(B)$
2. The proof is the same as (a), with intersection replacing union and with *and* replacing *or* throughout.
3. The proof is the same as (a), with set difference replacing union and with *and not* replacing *or* throughout.

4. Suppose $A \subseteq B$. If $x \in f^{-1}(A)$ then $f(x) \in A$ and hence $f(x) \in B$, so $x \in f^{-1}(B)$.
5. If A and B are disjoint, then from (b), $f^{-1}(A) \cap f^{-1}(B) = f^{-1}(A \cap B) = f^{-1}(\emptyset) = \emptyset$.

The result in part (a) holds for arbitrary unions, and the result in part (b) holds for arbitrary intersections. No new ideas are involved; only the notation is more complicated.

Suppose that $\{A_i : i \in I\}$ is a collection of subsets of T , where I is a nonempty index set. Then

1. $f^{-1}(\bigcup_{i \in I} A_i) = \bigcup_{i \in I} f^{-1}(A_i)$
2. $f^{-1}(\bigcap_{i \in I} A_i) = \bigcap_{i \in I} f^{-1}(A_i)$

Proof

1. $x \in f^{-1}(\bigcup_{i \in I} A_i)$ if and only if $f(x) \in \bigcup_{i \in I} A_i$ if and only if $f(x) \in A_i$ for some $i \in I$ if and only if $x \in f^{-1}(A_i)$ for some $i \in I$ if and only if $x \in \bigcup_{i \in I} f^{-1}(A_i)$
2. The proof is the same as (a), with intersection replacing union and with *for every* replacing *for some*.

Forward Images

Forward images of a function are a naturally complement to inverse images.

Suppose again that $f : S \rightarrow T$. If $A \subseteq S$, the *forward image* of A under f is the subset of T given by

$$f(A) = \{f(x) : x \in A\} \quad (1.2.5)$$

So $f(A)$ is the range of f restricted to A .

Figure 1.2.3: The forward image of A under f

Technically, the forward images define a new function from $\mathcal{P}(S)$ into $\mathcal{P}(T)$, but we use the same symbol f for this new function as for the underlying function from S into T that we started with. Again, the two functions are very different, but usually no confusion results.

It might seem that forward images are more natural than inverse images, but in fact, the inverse images are much more important than the forward ones (at least in probability and measure theory). Fortunately, the inverse images are nicer as well—unlike the inverse images, the forward images do not preserve all of the set operations.

Suppose that $f : S \rightarrow T$, and that $A, B \subseteq S$. Then

1. $f(A \cup B) = f(A) \cup f(B)$.
2. $f(A \cap B) \subseteq f(A) \cap f(B)$. Equality holds if f is one-to-one.
3. $f(A) \setminus f(B) \subseteq f(A \setminus B)$. Equality holds if f is one-to-one.
4. If $A \subseteq B$ then $f(A) \subseteq f(B)$.

Proof

1. Suppose $y \in f(A \cup B)$. Then $y = f(x)$ for some $x \in A \cup B$. If $x \in A$ then $y \in f(A)$ and if $x \in B$ then $y \in f(B)$. In both cases $y \in f(A) \cup f(B)$. Conversely suppose $y \in f(A) \cup f(B)$. If $y \in f(A)$ then $y = f(x)$ for some $x \in A$. But then $x \in A \cup B$ so $y \in f(A \cup B)$. Similarly, if $y \in f(B)$ then $y = f(x)$ for some $x \in B$. But then $x \in A \cup B$ so $y \in f(A \cup B)$.
2. If $y \in f(A \cap B)$ then $y = f(x)$ for some $x \in A \cap B$. But then $x \in A$ so $y \in f(A)$ and $x \in B$ so $y \in f(B)$ and hence $y \in f(A) \cap f(B)$. Conversely, suppose that $y \in f(A) \cap f(B)$. Then $y \in f(A)$ and $y \in f(B)$, so there exists $x \in A$ with $f(x) = y$ and there exists $u \in B$ with $f(u) = y$. At this point, we can go no further. But if f is one-to-one, then $u = x$ and hence $x \in A$ and $x \in B$. Thus $x \in A \cap B$ so $y \in f(A \cap B)$.

3. Suppose $y \in f(A) \setminus f(B)$. Then $y \in f(A)$ and $y \notin f(B)$. Hence $y = f(x)$ for some $x \in A$ and $y \neq f(u)$ for every $u \in B$. Thus, $x \notin B$ so $x \in A \setminus B$ and hence $y \in f(A \setminus B)$. Conversely, suppose $y \in f(A \setminus B)$. Then $y = f(x)$ for some $x \in A \setminus B$. Hence $x \in A$ so $y \in f(A)$. Again, the proof breaks down at this point. However, if f is one-to-one and $f(u) = y$ for some $u \in B$, then $u = x$ so $x \in B$, a contradiction. Hence $f(u) \neq y$ for every $u \in B$ so $y \notin f(B)$. Thus $y \in f(A \setminus B)$.
4. Suppose $A \subseteq B$. If $y \in f(A)$ then $y = f(x)$ for some $x \in A$. But then $x \in B$ so $y \in f(B)$.

The result in part (a) hold for arbitrary unions, and the results in part (b) hold for arbitrary intersections. No new ideas are involved; only the notation is more complicated.

Suppose that $\{A_i : i \in I\}$ is a collection of subsets of S , where I is a nonempty index set. Then

1. $f\left(\bigcup_{i \in I} A_i\right) = \bigcup_{i \in I} f(A_i)$.
2. $f\left(\bigcap_{i \in I} A_i\right) \subseteq \bigcap_{i \in I} f(A_i)$. Equality holds if f is one-to-one.

Proof

1. $y \in f\left(\bigcup_{i \in I} A_i\right)$ if and only if $y = f(x)$ for some $x \in \bigcup_{i \in I} A_i$ if and only if $y = f(x)$ for some $x \in A_i$ and some $i \in I$ if and only if $y \in f(A_i)$ for some $i \in I$ if and only if $y \in \bigcup_{i \in I} f(A_i)$.
2. If $y \in f\left(\bigcap_{i \in I} A_i\right)$ then $y = f(x)$ for some $x \in \bigcap_{i \in I} A_i$. Hence $x \in A_i$ for every $i \in I$ so $y \in f(A_i)$ for every $i \in I$ and thus $y \in \bigcap_{i \in I} f(A_i)$. Conversely, suppose that $y \in \bigcap_{i \in I} f(A_i)$. Then $y \in f(A_i)$ for every $i \in I$. Hence for every $i \in I$ there exists $x_i \in A_i$ with $y = f(x_i)$. If f is one-to-one, $x_i = x_j$ for all $i, j \in I$. Call the common value x . Then $x \in A_i$ for every $i \in I$ so $x \in \bigcap_{i \in I} A_i$ and therefore $y \in f\left(\bigcap_{i \in I} A_i\right)$.

Suppose again that $f : S \rightarrow T$. As noted earlier, the forward images of f define a function from $\mathcal{P}(S)$ into $\mathcal{P}(T)$ and the inverse images define a function from $\mathcal{P}(T)$ into $\mathcal{P}(S)$. One might hope that these functions are inverses of one another, but alas no.

Suppose that $f : S \rightarrow T$.

1. $A \subseteq f^{-1}[f(A)]$ for $A \subseteq S$. Equality holds if f is one-to-one.
2. $f[f^{-1}(B)] \subseteq B$ for $B \subseteq T$. Equality holds if f is onto.

Proof

1. If $x \in A$ then $f(x) \in f(A)$ and hence $x \in f^{-1}[f(A)]$. Conversely suppose that $x \in f^{-1}[f(A)]$. Then $f(x) \in f(A)$ so $f(x) = f(u)$ for some $u \in A$. At this point we can go no further. But if f is one-to-one, then $u = x$ and hence $x \in A$.
2. Suppose $y \in f[f^{-1}(B)]$. Then $y = f(x)$ for some $x \in f^{-1}(B)$. But then $y = f(x) \in B$. Conversely suppose that f is onto and $y \in B$. There exist $x \in S$ with $f(x) = y$. Hence $x \in f^{-1}(B)$ and so $y \in f[f^{-1}(B)]$.

Spaces of Real Functions

Real-valued function on a given set S are of particular importance. The usual arithmetic operations on such functions are defined *pointwise*.

Suppose that $f, g : S \rightarrow \mathbb{R}$ and $c \in \mathbb{R}$, then $f + g, f - g, fg, cf, f/g : S \rightarrow \mathbb{R}$ are defined as follows for all $x \in S$.

1. $(f + g)(x) = f(x) + g(x)$
2. $(f - g)(x) = f(x) - g(x)$
3. $(fg)(x) = f(x)g(x)$
4. $(cf)(x) = cf(x)$
5. $(f/g)(x) = f(x)/g(x)$ assuming that $g(x) \neq 0$ for $x \in S$.

Now let \mathcal{V} denote the collection of all functions from the given set S into \mathbb{R} . A fact that is very important in probability as well as other branches of analysis is that \mathcal{V} , with addition and scalar multiplication as defined above, is a *vector space*. The *zero function* $\mathbf{0}$ is defined, of course, by $\mathbf{0}(x) = 0$ for all $x \in S$.

$(\mathcal{V}, +, \cdot)$ is a vector space over \mathbb{R} . That is, for all $f, g, h \in \mathcal{V}$ and $a, b \in \mathbb{R}$

1. $f + g = g + f$, the *commutative property* of vector addition.
2. $f + (g + h) = (f + g) + h$, the *associative property* of vector addition.

3. $a(f + g) = af + ag$, scalar multiplication *distributes* over vector addition.
4. $(a + b)f = af + bf$, scalar multiplication *distributive* over scalar addition.
5. $f + \mathbf{0} = f$, the existence of an *zero vector*.
6. $f + (-f) = \mathbf{0}$, the existence of *additive inverses*.
7. $1 \cdot f = f$, the *unity property*.

Proof

Each of these properties follows from the corresponding property in \mathbb{R} .

Various subspaces of \mathcal{V} are important in probability as well. We will return to the discussion of vector spaces of functions in the sections on partial orders and in the advanced sections on metric spaces and measure theory.

Indicator Functions

For our next discussion, suppose that S is the universal set, so that all other sets mentioned are subsets of S .

Suppose that $A \subseteq S$. The *indicator function* of A is the function $\mathbf{1}_A : S \rightarrow \{0, 1\}$ defined as follows:

$$\mathbf{1}_A(x) = \begin{cases} 1, & x \in A \\ 0, & x \notin A \end{cases} \quad (1.2.6)$$

Thus, the indicator function of A simply *indicates* whether or not $x \in A$ for each $x \in S$. Conversely, any function on S that just takes the values 0 and 1 is an indicator function.

If $f : S \rightarrow \{0, 1\}$ then f is the indicator function of the set $A = f^{-1}\{1\} = \{x \in S : f(x) = 1\}$.

Thus, there is a one-to-one correspondence between $\mathcal{P}(S)$, the power set of S , and the collection of indicator functions $\{0, 1\}^S$. The next result shows how the *set algebra* of subsets corresponds to the *arithmetic algebra* of the indicator functions.

Suppose that $A, B \subseteq S$. Then

1. $\mathbf{1}_{A \cap B} = \mathbf{1}_A \mathbf{1}_B = \min\{\mathbf{1}_A, \mathbf{1}_B\}$
2. $\mathbf{1}_{A \cup B} = 1 - (1 - \mathbf{1}_A)(1 - \mathbf{1}_B) = \max\{\mathbf{1}_A, \mathbf{1}_B\}$
3. $\mathbf{1}_{A^c} = 1 - \mathbf{1}_A$
4. $\mathbf{1}_{A \setminus B} = \mathbf{1}_A(1 - \mathbf{1}_B)$
5. $A \subseteq B$ if and only if $\mathbf{1}_A \leq \mathbf{1}_B$

Proof

1. Note that both functions on the right just take the values 0 and 1. Moreover, $\mathbf{1}_A(x)\mathbf{1}_B(x) = \min\{\mathbf{1}_A(x), \mathbf{1}_B(x)\} = 1$ if and only if $x \in A$ and $x \in B$.
2. Note that both function on the right just take the values 0 and 1. Moreover, $1 - (1 - \mathbf{1}_A(x))(1 - \mathbf{1}_B(x)) = \max\{\mathbf{1}_A(x), \mathbf{1}_B(x)\} = 1$ if and only if $x \in A$ or $x \in B$.
3. Note that $1 - \mathbf{1}_A$ just takes the values 0 and 1. Moreover, $1 - \mathbf{1}_A(x) = 1$ if and only if $x \notin A$.
4. Note that $\mathbf{1}_{A \setminus B} = \mathbf{1}_{A \cap B^c} = \mathbf{1}_A \mathbf{1}_{B^c} = \mathbf{1}_A(1 - \mathbf{1}_B)$ by parts (a) and (c).
5. Since both functions just take the values 0 and 1, note that $\mathbf{1}_A \leq \mathbf{1}_B$ if and only if $\mathbf{1}_A(x) = 1$ implies $\mathbf{1}_B(x) = 1$. But in turn, this is equivalent to $A \subseteq B$.

The results in part (a) extends to arbitrary intersections and the results in part (b) extends to arbitrary unions.

Suppose that $\{A_i : i \in I\}$ is a collection of subsets of S , where I is a nonempty index set. Then

1. $\mathbf{1}_{\bigcap_{i \in I} A_i} = \prod_{i \in I} \mathbf{1}_{A_i} = \min\{\mathbf{1}_{A_i} : i \in I\}$
2. $\mathbf{1}_{\bigcup_{i \in I} A_i} = 1 - \prod_{i \in I} (1 - \mathbf{1}_{A_i}) = \max\{\mathbf{1}_{A_i} : i \in I\}$

Proof

In general, a product over an infinite index set may not make sense. But if all of the factors are either 0 or 1, as they are here, then we can simply define the product to be 1 if all of the factors are 1, and 0 otherwise.

1. The functions in the middle and on the right just take the values 0 and 1. Moreover, both take the value 1 at $x \in S$ if and only if $x \in A_i$ for every $i \in I$.
2. The functions in the middle and on the right just take the values 0 and 1. Moreover, both take the value 1 at $x \in S$ if and only if $x \in A_i$ for some $i \in I$.

Multisets

A *multiset* is like an ordinary set, except that elements may be repeated. A multiset A (with elements from a universal set S) can be uniquely associated with its *multiplicity function* $m_A : S \rightarrow \mathbb{N}$, where $m_A(x)$ is the number of times that element x is in A for each $x \in S$. So the multiplicity function of a multiset plays the same role that an indicator function does for an ordinary set. Multisets arise naturally when objects are sampled with replacement (but without regard to order) from a population. Various sampling models are explored in the section on Combinatorial Structures. We will not go into detail about the operations on multisets, but the definitions are straightforward generalizations of those for ordinary sets.

Suppose that A and B are multisets with elements from the universal set S . Then

1. $A \subseteq B$ if and only if $m_A \leq m_B$
2. $m_{A \cup B} = \max\{m_A, m_B\}$
3. $m_{A \cap B} = \min\{m_A, m_B\}$
4. $m_{A+B} = m_A + m_B$

Product Spaces

Using functions, we can generalize the Cartesian products studied earlier. In this discussion, we suppose that S_i is a set for each i in a nonempty index set I .

Define the *product set*

$$\prod_{i \in I} S_i = \left\{ x : x \text{ is a function from } I \text{ into } \bigcup_{i \in I} S_i \text{ such that } x(i) \in S_i \text{ for each } i \in I \right\} \quad (1.2.7)$$

Note that except for being nonempty, there are no assumptions on the cardinality of the index set I . Of course, if $I = \{1, 2, \dots, n\}$ for some $n \in \mathbb{N}_+$, or if $I = \mathbb{N}_+$ then this construction reduces to $S_1 \times S_2 \times \dots \times S_n$ and to $S_1 \times S_2 \times \dots$, respectively. Since we want to make the notation more closely resemble that of simple Cartesian products, we will write x_i instead of $x(i)$ for the value of the function x at $i \in I$, and we sometimes refer to this value as the *i th coordinate* of x . Finally, note that if $S_i = S$ for each $i \in I$, then $\prod_{i \in I} S_i$ is simply the set of all functions from I into S , which we denoted by S^I above.

For $j \in I$ define the *projection* $p_j : \prod_{i \in I} S_i \rightarrow S_j$ by $p_j(x) = x_j$ for $x \in \prod_{i \in I} S_i$.

So $p_j(x)$ is just the j th coordinate of x . The projections are of basic importance for product spaces. In particular, we have a better way of looking at projections of a subset of a product set.

For $A \subseteq \prod_{i \in I} S_i$ and $j \in I$, the *forward image* $p_j(A)$ is the projection of A onto S_j .

Proof

Note that $p_j(A) = \{p_j(x) : x \in A\} = \{x_j : x \in A\}$, the set of all j th coordinates of the points in A .

So the properties of projection that we studied in the last section are just special cases of the properties of forward images. Projections also allow us to get *coordinate functions* in a simple way.

Suppose that R is a set, and that $f : R \rightarrow \prod_{i \in I} S_i$. If $j \in I$ then $p_j \circ f : R \rightarrow S_j$ is the *j th coordinate function* of f .

Proof

Note that for $x \in R$, $(p_j \circ f)(x) = p_j[f(x)] = f_j(x)$, the j th coordinate of $f(x) \in \prod_{i \in I} S_i$.

This will look more familiar for a simple cartesian product. If $f : R \rightarrow S_1 \times S_2 \times \dots \times S_n$, then $f = (f_1, f_2, \dots, f_n)$ where $f_j : R \rightarrow S_j$ is the j th coordinate function for $j \in \{1, 2, \dots, n\}$.

Cross sections of a subset of a product set can be expressed in terms of **inverse images** of a function. First we need some additional notation. Suppose that our index set I has at least two elements. For $j \in I$ and $u \in S_j$, define $j_u : \prod_{i \in I - \{j\}} S_i \rightarrow \prod_{i \in I} S_i$ by $j_u(x) = y$ where $y_i = x_i$ for $i \in I - \{j\}$ and $y_j = u$. In words, j_u takes a point $x \in \prod_{i \in I - \{j\}} S_i$ and assigns u to coordinate j to produce the point $y \in \prod_{i \in I} S_i$.

In the setting above, if $j \in I$, $u \in S_j$ and $A \subseteq \prod_{i \in I} S_i$ then $j_u^{-1}(A)$ is the cross section of A in the j th coordinate at u .

Proof

This follows from the definition of cross section: $j_u^{-1}(A)$ is the set of all $x \in \prod_{i \in I - \{j\}} S_i$ such that y defined above is in A and has j th coordinate u .

Let's look at this for the product of two sets S and T . For $x \in S$, the function $1_x : T \rightarrow S \times T$ is given by $1_x(y) = (x, y)$. Similarly, for $y \in T$, the function $2_y : S \rightarrow S \times T$ is given by $2_y(x) = (x, y)$. Suppose now that $A \subseteq S \times T$. If $x \in S$, then $1_x^{-1}(A) = \{y \in T : (x, y) \in A\}$, the very definition of the cross section of A in the first coordinate at x . Similarly, if $y \in T$, then $2_y^{-1}(A) = \{x \in S : (x, y) \in A\}$, the very definition of the cross section of A in the second coordinate at y . This construction is not particularly important except to show that cross sections are inverse images. Thus the fact that cross sections preserve all of the set operations is a simple consequence of the fact that inverse images generally preserve set operations.

Operators

Sometimes functions have special interpretations in certain settings.

Suppose that S is a set.

1. A function $f : S \rightarrow S$ is sometimes called a *unary operator* on S .
2. A function $g : S \times S \rightarrow S$ is sometimes called a *binary operator* on S .

As the names suggests, a unary operator f *operates* on an element $x \in S$ to produce a new element $f(x) \in S$. Similarly, a binary operator g *operates* on a pair of elements $(x, y) \in S \times S$ to produce a new element $g(x, y) \in S$. The *arithmetic operators* are quintessential examples:

The following are operators on \mathbb{R} :

1. $\text{minus}(x) = -x$ is a unary operator.
2. $\text{sum}(x, y) = x + y$ is a binary operator.
3. $\text{product}(x, y) = x y$ is a binary operator.
4. $\text{difference}(x, y) = x - y$ is a binary operator.

For a fixed universal set S , the *set operators* studied in the section on Sets provide other examples.

For a given set S , the following are operators on $\mathcal{P}(S)$:

1. $\text{complement}(A) = A^c$ is a unary operator.
2. $\text{union}(A, B) = A \cup B$ is a binary operator.
3. $\text{intersect}(A, B) = A \cap B$ is a binary operator.
4. $\text{difference}(A, B) = A \setminus B$ is a binary operator.

As these examples illustrate, a binary operator is often written as $x f y$ rather than $f(x, y)$. Still, it is useful to know that operators are simply functions of a special type.

Suppose that f is a unary operator on a set S , g is a binary operator on S , and that $A \subseteq S$.

1. A is *closed* under f if $x \in A$ implies $f(x) \in A$.
2. A is *closed* under g if $(x, y) \in A \times A$ implies $g(x, y) \in A$.

Thus if A is closed under the unary operator f , then f restricted to A is unary operator on A . Similary if A is closed under the binary operator g , then g restricted to $A \times A$ is a binary operator on A . Let's return to our most basic example.

For the arithmetic operators on \mathbb{R} ,

1. \mathbb{N} is closed under plus and times, but not under minus and difference.
2. \mathbb{Z} is closed under plus, times, minus, and difference.
3. \mathbb{Q} is closed under plus, times, minus, and difference.

Many properties that you are familiar with for special operators (such as the arithmetic and set operators) can now be formulated generally.

Suppose that f and g are binary operators on a set S . In the following definitions, x , y , and z are arbitrary elements of S .

1. f is *commutative* if $f(x, y) = f(y, x)$, that is, $x f y = y f x$
2. f is *associative* if $f(x, f(y, z)) = f(f(x, y), z)$, that is, $x f (y f z) = (x f y) f z$
3. g *distributes* over f (on the left) if $g(x, f(y, z)) = f(g(x, y), g(x, z))$, that is, $x g (y f z) = (x g y) f (x g z)$

The Axiom of Choice

Suppose that \mathcal{S} is a collection of nonempty subsets of a set S . The *axiom of choice* states that there exists a function $f : \mathcal{S} \rightarrow S$ with the property that $f(A) \in A$ for each $A \in \mathcal{S}$. The function f is known as a *choice function*.

Stripped of most of the mathematical jargon, the idea is very simple. Since each set $A \in \mathcal{S}$ is nonempty, we can select an element of A ; we will call the element we select $f(A)$ and thus our selections define a function. In fact, you may wonder why we need an axiom at all. The problem is that we have not given a *rule* (or procedure or algorithm) for selecting the elements of the sets in the collection. Indeed, we may not know enough about the sets in the collection to define a specific rule, so in such a case, the axiom of choice simply guarantees the existence of a choice function. Some mathematicians, known as *constructionists* do not accept the axiom of choice, and insist on well defined rules for constructing functions.

A nice consequence of the axiom of choice is a type of duality between one-to-one functions and onto functions.

Suppose that f is a function from a set S onto a set T . There exists a one-to-one function g from T into S .

Proof.

For each $y \in T$, the set $f^{-1}\{y\}$ is non-empty, since f is onto. By the axiom of choice, we can select an element $g(y)$ from $f^{-1}\{y\}$ for each $y \in T$. The resulting function g is one-to-one.

Suppose that f is a one-to-one function from a set S into a set T . There exists a function g from T onto S .

Proof.

Fix a special element $x_0 \in S$. If $y \in \text{range}(f)$, there exists a unique $x \in S$ with $f(x) = y$. Define $g(y) = x$. If $y \notin \text{range}(f)$, define $g(y) = x_0$. The function g is onto.

Computational Exercises

Some Elementary Functions

Each of the following rules defines a function from \mathbb{R} into \mathbb{R} .

- $f(x) = x^2$
- $g(x) = \sin(x)$
- $h(x) = \lfloor x \rfloor$
- $u(x) = \frac{e^x}{1+e^x}$

Find the range of the function and determine if the function is one-to-one in each of the following cases:

1. f
2. g
3. h
4. u

Answer

1. Range $[0, \infty)$. Not one-to-one.
2. Range $[-1, 1]$. Not one-to-one.
3. Range \mathbb{Z} . Not one-to-one.
4. Range $(0, 1)$. One-to-one.

Find the following inverse images:

1. $f^{-1}[4, 9]$
2. $g^{-1}\{0\}$
3. $h^{-1}\{2, 3, 4\}$

Answer

1. $[-3, -2] \cup [2, 3]$
2. $\{n\pi : n \in \mathbb{Z}\}$
3. $[2, 5)$

The function u is one-to-one. Find (that is, give the domain and rule for) the inverse function u^{-1} .

Answer

$$u^{-1}(p) = \ln\left(\frac{p}{1-p}\right) \text{ for } p \in (0, 1)$$

Give the rule and find the range for each of the following functions:

1. $f \circ g$
2. $g \circ f$
3. $h \circ g \circ f$

Answer

1. $(f \circ g)(x) = \sin^2(x)$. Range $[0, 1]$
2. $(g \circ f)(x) = \sin(x^2)$. Range $[-1, 1]$
3. $(h \circ g \circ f)(x) = \lfloor \sin(x^2) \rfloor$. Range $\{-1, 0, 1\}$

Note that $f \circ g$ and $g \circ f$ are well-defined functions from \mathbb{R} into \mathbb{R} , but $f \circ g \neq g \circ f$.

Dice

Let $S = \{1, 2, 3, 4, 5, 6\}^2$. This is the set of possible outcomes when a pair of standard dice are thrown. Let f, g, u , and v be the functions from S into \mathbb{Z} defined by the following rules:

- $f(x, y) = x + y$
- $g(x, y) = y - x$
- $u(x, y) = \min\{x, y\}$
- $v(x, y) = \max\{x, y\}$

In addition, let F and U be the functions defined by $F = (f, g)$ and $U = (u, v)$.

Find the range of each of the following functions:

1. f
2. g
3. u
4. v
5. U

Answer

1. $\{2, 3, 4, \dots, 12\}$
2. $\{-5, -4, \dots, 4, 5\}$

3. $\{1, 2, 3, 4, 5, 6\}$
4. $\{1, 2, 3, 4, 5, 6\}$
5. $\{(i, j) \in \{1, 2, 3, 4, 5, 6\}^2 : i \leq j\}$

Give each of the following inverse images in list form:

1. $f^{-1}\{6\}$
2. $u^{-1}\{3\}$
3. $v^{-1}\{4\}$
4. $U^{-1}\{(3, 4)\}$

Answer

1. $\{(1, 5), (2, 4), (3, 3), (4, 2), (5, 1)\}$
2. $\{(3, 3), (3, 4), (4, 3), (3, 5), (5, 3), (3, 6), (6, 3)\}$
3. $\{(1, 4), (4, 1), (2, 4), (4, 2), (3, 4), (4, 3), (4, 4)\}$
4. $\{(3, 4), (4, 3)\}$

Find each of the following compositions:

1. $f \circ U$
2. $g \circ U$
3. $u \circ F$
4. $v \circ F$
5. $F \circ U$
6. $U \circ F$

Answer

1. $f \circ U = f$
2. $g \circ U = |g|$
3. $u \circ F = g$
4. $v \circ F = f$
5. $F \circ U = (f, |g|)$
6. $U \circ F = (g, f)$

Note that while $f \circ U$ is well-defined, $U \circ f$ is not. Note also that $f \circ U = f$ even though U is not the identity function on S .

Bit Strings

Let $n \in \mathbb{N}_+$ and let $S = \{0, 1\}^n$ and $T = \{0, 1, \dots, n\}$. Recall that the elements of S are bit strings of length n , and could represent the possible outcomes of n tosses of a coin (where 1 means heads and 0 means tails). Let $f : S \rightarrow T$ be the function defined by $f(x_1, x_2, \dots, x_n) = \sum_{i=1}^n x_i$. Note that $f(\mathbf{x})$ is just the number of 1s in the bit string \mathbf{x} . Let $g : T \rightarrow S$ be the function defined by $g(k) = \mathbf{x}_k$ where \mathbf{x}_k denotes the bit string with k 1s followed by $n - k$ 0s.

Find each of the following

1. $f \circ g$
2. $g \circ f$

Answer

1. $f \circ g : T \rightarrow T$ and $(f \circ g)(k) = k$.
2. $g \circ f : S \rightarrow S$ and $(g \circ f)(\mathbf{x}) = \mathbf{x}_k$ where $k = f(\mathbf{x}) = \sum_{i=1}^n x_i$. In words, $(g \circ f)(\mathbf{x})$ is the bit string with the same number of 1s as \mathbf{x} , but rearranged so that all the 1s come first.

In the previous exercise, note that $f \circ g$ and $g \circ f$ are both well-defined, but have different domains, and so of course are not the same. Note also that $f \circ g$ is the identity function on T , but f is not the inverse of g . Indeed f is not one-to-one, and so does not have an inverse. However, f restricted to $\{\mathbf{x}_k : k \in T\}$ (the range of g) is one-to-one and is the inverse of g .

Let $n = 4$. Give $f^{-1}(\{k\})$ in list form for each $k \in T$.

Answer

1. $f^{-1}(\{0\}) = \{0000\}$
2. $f^{-1}(\{1\}) = \{1000, 0100, 0010, 0001\}$
3. $f^{-1}(\{2\}) = \{1100, 1010, 1001, 0110, 0101, 0011\}$
4. $f^{-1}(\{3\}) = \{1110, 1101, 1011, 0111\}$
5. $f^{-1}(\{4\}) = \{1111\}$

Again let $n = 4$. Let $A = \{1000, 1010\}$ and $B = \{1000, 1100\}$. Give each of the following in list form:

1. $f(A)$
2. $f(B)$
3. $f(A \cap B)$
4. $f(A) \cap f(B)$
5. $f^{-1}(f(A))$

Answer

1. $\{1, 2\}$
2. $\{1, 2\}$
3. $\{1\}$
4. $\{1, 2\}$
5. $\{1000, 0100, 0010, 0001, 1100, 1010, 1001, 0110, 0101, 0011\}$

In the previous exercise, note that $f(A \cap B) \subset f(A) \cap f(B)$ and $A \subset f^{-1}(f(A))$.

Indicator Functions

Suppose that A and B are subsets of a universal set S . Express, in terms of $\mathbf{1}_A$ and $\mathbf{1}_B$, the indicator function of each of the 14 non-trivial sets that can be constructed from A and B . Use the Venn diagram app to help.

Answer

1. $\mathbf{1}_A$
2. $\mathbf{1}_B$
3. $\mathbf{1}_{A^c} = 1 - \mathbf{1}_A$
4. $\mathbf{1}_{B^c} = 1 - \mathbf{1}_B$
5. $\mathbf{1}_{A \cap B} = \mathbf{1}_A \mathbf{1}_B$
6. $\mathbf{1}_{A \cup B} = \mathbf{1}_A + \mathbf{1}_B - \mathbf{1}_A \mathbf{1}_B$
7. $\mathbf{1}_{A \cap B^c} = \mathbf{1}_A - \mathbf{1}_A \mathbf{1}_B$
8. $\mathbf{1}_{B \cap A^c} = \mathbf{1}_B - \mathbf{1}_A \mathbf{1}_B$
9. $\mathbf{1}_{A \cup B^c} = 1 - \mathbf{1}_B + \mathbf{1}_A \mathbf{1}_B$
10. $\mathbf{1}_{B \cup A^c} = 1 - \mathbf{1}_A + \mathbf{1}_A \mathbf{1}_B$
11. $\mathbf{1}_{A^c \cap B^c} = 1 - \mathbf{1}_A - \mathbf{1}_B + \mathbf{1}_A \mathbf{1}_B$
12. $\mathbf{1}_{A^c \cup B^c} = 1 - \mathbf{1}_A \mathbf{1}_B$
13. $\mathbf{1}_{(A \cap B^c) \cup (B \cap A^c)} = \mathbf{1}_A + \mathbf{1}_B - 2\mathbf{1}_A \mathbf{1}_B$
14. $\mathbf{1}_{(A \cap B) \cup (A^c \cap B^c)} = 1 - \mathbf{1}_A - \mathbf{1}_B + 2\mathbf{1}_A \mathbf{1}_B$

Suppose that A , B , and C are subsets of a universal set S . Give the indicator function of each of the following, in terms of $\mathbf{1}_A$, $\mathbf{1}_B$, and $\mathbf{1}_C$ in sum-product form:

1. $D = \{x \in S : x \text{ is an element of exactly one of the given sets}\}$
2. $E = \{x \in S : x \text{ is an element of exactly two of the given sets}\}$

Answer

1. $\mathbf{1}_D = \mathbf{1}_A + \mathbf{1}_B + \mathbf{1}_C - 2(\mathbf{1}_A \mathbf{1}_B + \mathbf{1}_A \mathbf{1}_C + \mathbf{1}_B \mathbf{1}_C) + 3\mathbf{1}_A \mathbf{1}_B \mathbf{1}_C$
2. $\mathbf{1}_E = \mathbf{1}_A \mathbf{1}_B + \mathbf{1}_A \mathbf{1}_C + \mathbf{1}_B \mathbf{1}_C - 3\mathbf{1}_A \mathbf{1}_B \mathbf{1}_C$

Operators

Recall the standard arithmetic operators on \mathbb{R} discussed above.

We all know that sum is commutative and associative, and that product distributes over sum.

1. Is difference commutative?
2. Is difference associative?
3. Does product distribute over difference?
4. Does sum distributed over product?

Answer

1. No. $x - y \neq y - x$
2. No. $x - (y - z) \neq (x - y) - z$
3. Yes. $x(y - z) = (xy) - (xz)$
4. No. $x + (yz) \neq (x + y)(x + z)$

Multisets

Express the multiset A in list form that has the multiplicity function $m : \{a, b, c, d, e\} \rightarrow \mathbb{N}$ given by $m(a) = 2$, $m(b) = 3$, $m(c) = 1$, $m(d) = 0$, $m(e) = 4$.

Answer

$$A = \{a, a, b, b, b, c, e, e, e, e\}$$

Express the prime factors of 360 as a multiset in list form.

Answer

$$\{2, 2, 2, 3, 3, 5\}$$

This page titled [1.2: Functions](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

1.3: Relations

Relations play a fundamental role in probability theory, as in most other areas of mathematics.

Definitions and Constructions

Suppose that S and T are sets. A *relation* from S to T is a subset of the product set $S \times T$.

1. The *domain* of R is the set of first coordinates: $\text{domain}(R) = \{x \in S : (x, y) \in R \text{ for some } y \in T\}$.
2. The *range* of R is the set of second coordinates: $\text{range}(R) = \{y \in T : (x, y) \in R \text{ for some } x \in S\}$.

A relation from a set S to itself is a relation *on* S .

As the name suggests, a relation R from S into T is supposed to define a *relationship* between the elements of S and the elements of T , and so we usually use the more suggestive notation $x R y$ when $(x, y) \in R$. Note that the domain of R is the projections of R onto S and the range of R is the projection of R onto T .

Basic Examples

Suppose that S is a set and recall that $\mathcal{P}(S)$ denotes the power set of S , the collection of all subsets of S . The *membership relation* \in from S to $\mathcal{P}(S)$ is perhaps the most important and basic relationship in mathematics. Indeed, for us, it's a primitive (undefined) relationship—given x and A , we assume that we understand the meaning of the statement $x \in A$.

Another basic primitive relation is the *equality relation* $=$ on a given set of objects S . That is, given two objects x and y , we assume that we understand the meaning of the statement $x = y$.

Other basic relations that you have seen are

1. The subset relation \subseteq on $\mathcal{P}(S)$.
2. The order relation \leq on \mathbb{R}

These two belong to a special class of relations known as partial orders that we will study in the next section. Note that a function f from S into T is a special type of relation. To compare the two types of notation (relation and function), note that $x f y$ means that $y = f(x)$.

Constructions

Since a relation is just a set of ordered pairs, the set operations can be used to build new relations from existing ones.

if Q and R are relations from S to T , then so are $Q \cup R$, $Q \cap R$, $Q \setminus R$.

1. $x(Q \cup R)y$ if and only if $x Q y$ or $x R y$.
2. $x(Q \cap R)y$ if and only if $x Q y$ and $x R y$.
3. $x(Q \setminus R)y$ if and only if $x Q y$ but not $x R y$.
4. If $Q \subseteq R$ then $x Q y$ implies $x R y$.

If R is a relation from S to T and $Q \subseteq R$, then Q is a relation from S to T .

The restriction of a relation defines a new relation.

If R is a relation on S and $A \subseteq S$ then $R_A = R \cap (A \times A)$ is a relation on A , called the *restriction* of R to A .

The inverse of a relation also defines a new relation.

If R is a relation from S to T , the *inverse* of R is the relation from T to S defined by

$$y R^{-1} x \text{ if and only if } x R y \quad (1.3.1)$$

Equivalently, $R^{-1} = \{(y, x) : (x, y) \in R\}$. Note that any function f from S into T has an inverse *relation*, but only when the f is one-to-one is the inverse relation also a function (the inverse function). Composition is another natural way to create new relations

from existing ones.

Suppose that Q is a relation from S to T and that R is a relation from T to U . The *composition* $Q \circ R$ is the relation from S to U defined as follows: for $x \in S$ and $z \in U$, $x(Q \circ R)z$ if and only if there exists $y \in T$ such that $x Q y$ and $y R z$.

Note that the notation is inconsistent with the notation used for composition of functions, essentially because relations are read from left to right, while functions are read from right to left. Hopefully, the inconsistency will not cause confusion, since we will always use function notation for functions.

Basic Properties

The important classes of relations that we will study in the next couple of sections are characterized by certain basic properties. Here are the definitions:

Suppose that R is a relation on S .

1. R is *reflexive* if $x R x$ for all $x \in S$.
2. R is *irreflexive* if no $x \in S$ satisfies $x R x$.
3. R is *symmetric* if $x R y$ implies $y R x$ for all $x, y \in S$.
4. R is *anti-symmetric* if $x R y$ and $y R x$ implies $x = y$ for all $x, y \in S$.
5. R is *transitive* if $x R y$ and $y R z$ implies $x R z$ for all $x, y, z \in S$.

The proofs of the following results are straightforward, so be sure to try them yourself before reading the ones in the text.

A relation R on S is reflexive if and only if the equality relation $=$ on S is a subset of R .

Proof

This follows from the definitions. R is reflexive if and only if $(x, x) \in R$ for all $x \in S$.

A relation R on S is symmetric if and only if $R^{-1} = R$.

Proof

Suppose that R is symmetric. If $(x, y) \in R$ then $(y, x) \in R$ and hence $(x, y) \in R^{-1}$. If $(x, y) \in R^{-1}$ then $(y, x) \in R$ and hence $(x, y) \in R$. Thus $R = R^{-1}$. Conversely, suppose $R = R^{-1}$. If $(x, y) \in R$ then $(x, y) \in R^{-1}$ and hence $(y, x) \in R$.

A relation R on S is transitive if and only if $R \circ R \subseteq R$.

Proof

Suppose that R is transitive. If $(x, z) \in R \circ R$ then there exists $y \in S$ such that $(x, y) \in R$ and $(y, z) \in R$. But then $(x, z) \in R$ by transitivity. Hence $R \circ R \subseteq R$. Conversely, suppose that $R \circ R \subseteq R$. If $(x, y) \in R$ and $(y, z) \in R$ then $(x, z) \in R \circ R$ and hence $(x, z) \in R$. Hence R is transitive.

A relation R on S is antisymmetric if and only if $R \cap R^{-1}$ is a subset of the equality relation $=$ on S .

Proof

Restated, this result is that R is antisymmetric if and only if $(x, y) \in R \cap R^{-1}$ implies $x = y$. Thus suppose that R is antisymmetric. If $(x, y) \in R \cap R^{-1}$ then $(x, y) \in R$ and $(x, y) \in R^{-1}$. But then $(y, x) \in R$ so by antisymmetry, $x = y$. Conversely suppose that $(x, y) \in R \cap R^{-1}$ implies $x = y$. If $(x, y) \in R$ and $(y, x) \in R$ then $(x, y) \in R^{-1}$ and hence $(x, y) \in R \cap R^{-1}$. Thus $x = y$ so R is antisymmetric.

Suppose that Q and R are relations on S . For each property below, if both Q and R have the property, then so does $Q \cap R$.

1. reflexive
2. symmetric
3. transitive

Proof

1. Suppose that Q and R are reflexive. Then $(x, x) \in Q$ and $(x, x) \in R$ for each $x \in S$ and hence $(x, x) \in Q \cap R$ for each $x \in S$. Thus $Q \cap R$ is reflexive.
2. Suppose that Q and R are symmetric. If $(x, y) \in Q \cap R$ then $(x, y) \in Q$ and $(x, y) \in R$. Hence $(y, x) \in Q$ and $(y, x) \in R$ so $(y, x) \in Q \cap R$. Hence $Q \cap R$ is symmetric.
3. Suppose that Q and R are transitive. If $(x, y) \in Q \cap R$ and $(y, z) \in Q \cap R$ then $(x, y) \in Q$, $(x, y) \in R$, $(y, z) \in Q$, and $(y, z) \in R$. Hence $(x, z) \in Q$ and $(x, z) \in R$ so $(x, z) \in Q \cap R$. Hence $Q \cap R$ is transitive.

Suppose that R is a relation on a set S .

1. Give an explicit definition for the property R is not reflexive.
2. Give an explicit definition for the property R is not irreflexive.
3. Are any of the properties R is reflexive, R is not reflexive, R is irreflexive, R is not irreflexive equivalent?

Answer

1. R is not reflexive if and only if there exists $x \in S$ such that $(x, x) \notin R$.
2. R is not irreflexive if and only if there exists $x \in S$ such that $(x, x) \in R$.
3. Nope.

Suppose that R is a relation on a set S .

1. Give an explicit definition for the property R is not symmetric.
2. Give an explicit definition for the property R is not antisymmetric.
3. Are any of the properties R is symmetric, R is not symmetric, R is antisymmetric, R is not antisymmetric equivalent?

Answer

1. R is not symmetric if and only if there exist $x, y \in S$ such that $(x, y) \in R$ and $(y, x) \notin R$.
2. R is not antisymmetric if and only if there exist distinct $x, y \in S$ such that $(x, y) \in R$ and $(y, x) \in R$.
3. Nope.

Computational Exercises

Let R be the relation defined on \mathbb{R} by $x R y$ if and only if $\sin(x) = \sin(y)$. Determine if R has each of the following properties:

1. reflexive
2. symmetric
3. transitive
4. irreflexive
5. antisymmetric

Answer

1. yes
2. yes
3. yes
4. no
5. no

The relation R in the previous exercise is a member of an important class of equivalence relations.

Let R be the relation defined on \mathbb{R} by $x R y$ if and only if $x^2 + y^2 \leq 1$. Determine if R has each of the following properties:

1. reflexive
2. symmetric
3. transitive
4. irreflexive
5. antisymmetric

Answer

1. no
2. yes
3. no
4. no
5. no

1.4: Partial Orders

Partial orders are a special class of relations that play an important role in probability theory.

Basic Theory

Definitions

A *partial order* on a set S is a relation \preceq on S that is reflexive, anti-symmetric, and transitive. The pair (S, \preceq) is called a *partially ordered set*. So for all $x, y, z \in S$:

1. $x \preceq x$, the *reflexive property*
2. If $x \preceq y$ and $y \preceq x$ then $x = y$, the *antisymmetric property*
3. If $x \preceq y$ and $y \preceq z$ then $x \preceq z$, the *transitive property*

As the name and notation suggest, a partial order is a type of ordering of the elements of S . Partial orders occur naturally in many areas of mathematics, including probability. A partial order on a set naturally gives rise to several other relations on the set.

Suppose that \preceq is a partial order on a set S . The relations $\succeq, \prec, \succ, \perp$, and \parallel are defined as follows:

1. $x \succeq y$ if and only if $y \preceq x$.
2. $x \prec y$ if and only if $x \preceq y$ and $x \neq y$.
3. $x \succ y$ if and only if $y \prec x$.
4. $x \perp y$ if and only if $x \preceq y$ or $y \preceq x$.
5. $x \parallel y$ if and only if neither $x \preceq y$ nor $y \preceq x$.

Note that \succeq is the inverse of \preceq , and \succ is the inverse of \prec . Note also that $x \preceq y$ if and only if either $x \prec y$ or $x = y$, so the relation \prec completely determines the relation \preceq . The relation \prec is sometimes called a *strict* or *strong* partial order to distinguish it from the ordinary (weak) partial order \preceq . Finally, note that $x \perp y$ means that x and y are *related* in the partial order, while $x \parallel y$ means that x and y are *unrelated* in the partial order. Thus, the relations \perp and \parallel are complements of each other, as sets of ordered pairs. A total or linear order is a partial order in which there are no unrelated elements.

A partial order \preceq on S is a *total order* or *linear order* if for every $x, y \in S$, either $x \preceq y$ or $y \preceq x$.

Suppose that \preceq_1 and \preceq_2 are partial orders on a set S . Then \preceq_1 is a *sub-order* of \preceq_2 , or equivalently \preceq_2 is an *extension* of \preceq_1 if and only if $x \preceq_1 y$ implies $x \preceq_2 y$ for $x, y \in S$.

Thus if \preceq_1 is a suborder of \preceq_2 , then as sets of ordered pairs, \preceq_1 is a subset of \preceq_2 . We need one more relation that arises naturally from a partial order.

Suppose that \preceq is a partial order on a set S . For $x, y \in S$, y is said to *cover* x if $x \prec y$ but no element $z \in S$ satisfies $x \prec z \prec y$.

If S is finite, the *covering relation* completely determines the partial order, by virtue of the transitive property.

Suppose that \preceq is a partial order on a finite set S . The *covering graph* or *Hasse graph* of (S, \preceq) is the directed graph with vertex set S and directed edge set E , where $(x, y) \in E$ if and only if y covers x .

Thus, $x \prec y$ if and only if there is a directed path in the graph from x to y . Hasse graphs are named for the German mathematician Helmut Hasse. The graphs are often drawn with the edges directed upward. In this way, the directions can be inferred without having to actually draw arrows.

Basic Examples

Of course, the ordinary order \leq is a total order on the set of real numbers \mathbb{R} . The subset partial order is one of the most important in probability theory:

Suppose that S is a set. The *subset relation* \subseteq is a partial order on $\mathcal{P}(S)$, the power set of S .

Proof

We proved this result in the section on sets. To review, recall that for $A, B \in \mathcal{P}(S)$, $A \subseteq B$ means that $x \in A$ implies $x \in B$. Also $A = B$ means that $x \in A$ if and only if $x \in B$. Thus

1. $A \subseteq A$
2. $A \subseteq B$ and $B \subseteq A$ if and only if $A = B$
3. $A \subseteq B$ and $B \subseteq C$ imply $A \subseteq C$

Here is a partial order that arises naturally from arithmetic.

Let $|$ denote the *division relation* on the set of positive integers \mathbb{N}_+ . That is, $m | n$ if and only if there exists $k \in \mathbb{N}_+$ such that $n = km$. Then

1. $|$ is a partial order on \mathbb{N}_+ .
2. $|$ is a sub-order of the ordinary order \leq .

Proof

1. Clearly $n | n$ for $n \in \mathbb{N}_+$, since $n = 1 \cdot n$, so $|$ is reflexive. Suppose $m | n$ and $n | m$, where $m, n \in \mathbb{N}_+$. Then there exist $j, k \in \mathbb{N}_+$ such that $n = km$ and $m = jn$. Substituting gives $n = jkn$, and hence $j = k = 1$. Thus $m = n$ so $|$ is antisymmetric. Finally, suppose $m | n$ and $n | p$, where $m, n, p \in \mathbb{N}_+$. Then there exists $j, k \in \mathbb{N}_+$ such that $n = jm$ and $p = kn$. Substituting gives $p = jkm$, so $m | p$. Thus $|$ is transitive.
2. If $m, n \in \mathbb{N}_+$ and $m | n$, then there exists $k \in \mathbb{N}_+$ such that $n = km$. Since $k \geq 1$, $m \leq n$.

The set of functions from a set into a partial ordered set can itself be partially ordered in a natural way.

Suppose that S is a set and that (T, \preceq_T) is a partially ordered set, and let \mathcal{S} denote the set of functions $f : S \rightarrow T$. The relation \preceq on \mathcal{S} defined by $f \preceq g$ if and only if $f(x) \preceq_T g(x)$ for all $x \in S$ is a partial order on \mathcal{S} .

Proof

Suppose that $f, g, h \in \mathcal{S}$.

1. $f(x) \preceq_T f(x)$ for all $x \in S$, so $f \preceq f$.
2. If $f \preceq g$ and $g \preceq f$ then $f(x) \preceq_T g(x)$ and $g(x) \preceq_T f(x)$ for all $x \in S$. Hence $f(x) = g(x)$ for all $x \in S$ so $f = g$.
3. If $f \preceq g$ and $g \preceq h$ then $f(x) \preceq_T g(x)$ and $g(x) \preceq_T h(x)$ for all $x \in S$. Hence $f(x) \preceq_T h(x)$ for all $x \in S$ so $f \preceq h$.

Note that we don't need a partial order on the domain S .

Basic Properties

The proofs of the following basic properties are straightforward. Be sure to try them yourself before reading the ones in the text.

The inverse of a partial order is also a partial order.

Proof

Clearly the reflexive, antisymmetric and transitive properties hold for \succeq .

If \preceq is a partial order on S and A is a subset of S , then the restriction of \preceq to A is a partial order on A .

Proof

The reflexive, antisymmetric, and transitive properties given above hold for all $x, y, z \in S$ and hence hold for all $x, y, z \in A$.

The following theorem characterizes relations that correspond to strict order.

Let S be a set. A relation \preceq is a partial order on S if and only if \prec is transitive and irreflexive.

Proof

Suppose that \preceq is a partial order on S . Recall that \prec is defined by $x \prec y$ if and only if $x \preceq y$ and $x \neq y$. If $x \prec y$ and $y \prec z$ then $x \preceq y$ and $y \preceq z$, and so $x \preceq z$. On the other hand, if $x = z$ then $x \preceq y$ and $y \preceq x$ so $x = y$, a contradiction. Hence $x \neq z$ and so $x \prec z$. Therefore \prec is transitive. If $x \prec y$ then $x \neq y$ by definition, so \prec is irreflexive.

Conversely, suppose that \prec is a transitive and irreflexive relation on S . Recall that \preceq is defined by $x \preceq y$ if and only if $x \prec y$ or $x = y$. By definition then, \preceq is reflexive: $x \preceq x$ for every $x \in S$. Next, suppose that $x \preceq y$ and $y \preceq x$. If $x \prec y$ and $y \prec x$ then

$x \prec x$ by the transitive property of \prec . But this is a contradiction by the irreflexive property, so we must have $x = y$. Thus \preceq is antisymmetric. Suppose $x \preceq y$ and $y \preceq z$. There are four cases:

1. If $x \prec y$ and $y \prec z$ then $x \prec z$ by the transitive property of \prec .
2. If $x = y$ and $y \prec z$ then $x \prec z$ by substitution.
3. If $x \prec y$ and $y = z$ then $x \prec z$ by substitution.
4. If $x = y$ and $y = z$ then $x = z$ by the transitive property of $=$.

In all cases we have $x \preceq z$ so \preceq is transitive. Hence \preceq is a partial order on S .

Monotone Sets and Functions

Partial orders form a natural setting for increasing and decreasing sets and functions. Here are the definitions:

Suppose that \preceq is a partial order on a set S and that $A \subseteq S$. In the following definitions, x, y are arbitrary elements of S .

1. A is *increasing* if $x \in A$ and $x \preceq y$ imply $y \in A$.
2. A is *decreasing* if $y \in A$ and $x \preceq y$ imply $x \in A$.

Suppose that S is a set with partial order \preceq_S , T is a set with partial order \preceq_T , and that $f : S \rightarrow T$. In the following definitions, x, y are arbitrary elements of S .

1. f is *increasing* if and only if $x \preceq_S y$ implies $f(x) \preceq_T f(y)$.
2. f is *decreasing* if and only if $x \preceq_S y$ implies $f(x) \succeq_T f(y)$.
3. f is *strictly increasing* if and only if $x \prec_S y$ implies $f(x) \prec_T f(y)$.
4. f is *strictly decreasing* if and only if $x \prec_S y$ implies $f(x) \succ_T f(y)$.

Recall the definition of the **indicator function** $\mathbf{1}_A$ associated with a subset A of a universal set S : For $x \in S$, $\mathbf{1}_A(x) = 1$ if $x \in A$ and $\mathbf{1}_A(x) = 0$ if $x \notin A$.

Suppose that \preceq is a partial order on a set S and that $A \subseteq S$. Then

1. A is increasing if and only if $\mathbf{1}_A$ is increasing.
2. A is decreasing if and only if $\mathbf{1}_A$ is decreasing.

Proof

1. A is increasing if and only if $x \in A$ and $x \preceq y$ implies $y \in A$ if and only if $\mathbf{1}_A(x) = 1$ and $x \preceq y$ implies $\mathbf{1}_A(y) = 1$ if and only if $\mathbf{1}_A$ is increasing.
2. A is decreasing if and only if $y \in A$ and $x \preceq y$ implies $x \in A$ if and only if $\mathbf{1}_A(y) = 1$ and $x \preceq y$ implies $\mathbf{1}_A(x) = 1$ if and only if $\mathbf{1}_A$ is decreasing.

Isomorphism

Two partially ordered sets (S, \preceq_S) and (T, \preceq_T) are said to be *isomorphic* if there exists a one-to-one function f from S onto T such that $x \preceq_S y$ if and only if $f(x) \preceq_T f(y)$, for all $x, y \in S$. The function f is an *isomorphism*.

Generally, a mathematical *space* often consists of a set and various structures defined in terms of the set, such as relations, operators, or a collection of subsets. Loosely speaking, two mathematical spaces of the same type are *isomorphic* if there exists a one-to-one function from one of the sets onto the other that *preserves* the structures, and again, the function is called an *isomorphism*. The basic idea is that isomorphic spaces are mathematically identical, except for superficial matters of appearance. The word *isomorphism* is from the Greek and means *equal shape*.

Suppose that the partially ordered sets (S, \preceq_S) and (T, \preceq_T) are isomorphic, and that $f : S \rightarrow T$ is an isomorphism. Then f and f^{-1} are strictly increasing.

Proof

We need to show that for $x, y \in S$, $x \prec_S y$ if and only if $f(x) \prec_T f(y)$. If $x \prec_S y$ then by definition, $f(x) \preceq_T f(y)$. But if $f(x) = f(y)$ then $x = y$ since f is one-to-one. This is a contradiction, so $f(x) \prec_T f(y)$. Similarly, if $f(x) \prec_T f(y)$ then by definition, $x \preceq_S y$. But if $x = y$ then $f(x) = f(y)$, a contradiction. Hence $x \prec_S y$.

In a sense, the subset partial order is universal—every partially ordered set is isomorphic to (\mathcal{S}, \subseteq) for some collection of sets \mathcal{S} .

Suppose that \preceq is a partial order on a set S . Then there exists $\mathcal{S} \subseteq \mathcal{P}(S)$ such that (S, \preceq) is isomorphic to (\mathcal{S}, \subseteq) .

Proof

For each $x \in S$, let $A_x = \{u \in S : u \preceq x\}$, and then let $\mathcal{S} = \{A_x : x \in S\}$, so that $\mathcal{S} \subseteq \mathcal{P}(S)$. We will show that the function $x \mapsto A_x$ from S onto \mathcal{S} is one-to-one, and satisfies

$$x \preceq y \iff A_x \subseteq A_y \quad (1.4.1)$$

First, suppose that $x, y \in S$ and $A_x = A_y$. Then $x \in A_x$ so $x \in A_y$ and hence $x \preceq y$. Similarly, $y \in A_y$ so $y \in A_x$ and hence $y \preceq x$. Thus $x = y$, so the mapping is one-to-one. Next, suppose that $x \preceq y$. If $u \in A_x$ then $u \preceq x$ so $u \preceq y$ by the transitive property, and hence $u \in A_y$. Thus $A_x \subseteq A_y$. Conversely, suppose $A_x \subseteq A_y$. As before, $x \in A_x$, so $x \in A_y$ and hence $x \preceq y$.

Extremal Elements

Various types of *extremal elements* play important roles in partially ordered sets. Here are the definitions:

Suppose that \preceq is a partial order on a set S and that $A \subseteq S$.

1. An element $a \in A$ is the *minimum* element of A if and only if $a \preceq x$ for every $x \in A$.
2. An element $a \in A$ is a *minimal* element of A if and only if no $x \in A$ satisfies $x \prec a$.
3. An element $b \in A$ is the *maximum* element of A if and only if $b \succeq x$ for every $x \in A$.
4. An element $b \in A$ is a *maximal* element of A if and only if no $x \in A$ satisfies $x \succ b$.

In general, a set can have several maximal and minimal elements (or none). On the other hand,

The minimum and maximum elements of A , if they exist, are unique. They are denoted $\min(A)$ and $\max(A)$, respectively.

Proof

Suppose that a, b are minimum elements of A . Since $a, b \in A$ we have $a \preceq b$ and $b \preceq a$, so $a = b$ by the antisymmetric property. The proof for the maximum element is analogous.

Minimal, maximal, minimum, and maximum elements of a set must belong to that set. The following definitions relate to upper and lower bounds of a set, which do not have to belong to the set.

Suppose again that \preceq is a partial order on a set S and that $A \subseteq S$. Then

1. An element $u \in S$ is a *lower bound* for A if and only if $u \preceq x$ for every $x \in A$.
2. An element $v \in S$ is an *upper bound* for A if and only if $v \succeq x$ for every $x \in A$.
3. The *greatest lower bound* or *infimum* of A , if it exists, is the maximum of the set of lower bounds of A .
4. The *least upper bound* or *supremum* of A , if it exists, is the minimum of the set of upper bounds of A .

By (20), the greatest lower bound of A is unique, if it exists. It is denoted $\text{glb}(A)$ or $\inf(A)$. Similarly, the least upper bound of A is unique, if it exists, and is denoted $\text{lub}(A)$ or $\sup(A)$. Note that every element of S is a lower bound and an upper bound for \emptyset , since the conditions in the definition hold vacuously.

The symbols \wedge and \vee are also used for infimum and supremum, respectively, so $\bigwedge A = \inf(A)$ and $\bigvee A = \sup(A)$ if they exist. In particular, for $x, y \in S$, operator notation is more commonly used, so $x \wedge y = \inf\{x, y\}$ and $x \vee y = \sup\{x, y\}$. Partially ordered sets for which these elements always exist are important, and have a special name.

Suppose that \preceq is a partial order on a set S . Then (S, \preceq) is a *lattice* if $x \wedge y$ and $x \vee y$ exist for every $x, y \in S$.

For the subset partial order, the \inf and \sup operators correspond to intersection and union, respectively:

Let S be a set and consider the subset partial order \subseteq on $\mathcal{P}(S)$, the power set of S . Let \mathcal{A} be a nonempty subset of $\mathcal{P}(S)$, that is, a nonempty collection of subsets of S . Then

1. $\inf(\mathcal{A}) = \bigcap \mathcal{A}$
2. $\sup(\mathcal{A}) = \bigcup \mathcal{A}$

Proof

1. First, $\bigcap \mathcal{A} \subseteq A$ for every $A \in \mathcal{A}$ and hence $\bigcap \mathcal{A}$ is a lower bound of \mathcal{A} . If B is a lower bound of \mathcal{A} then $B \subseteq A$ for every $A \in \mathcal{A}$ and hence $B \subseteq \bigcap \mathcal{A}$. Therefore $\bigcap \mathcal{A}$ is the greatest lower bound.
2. First, $A \subseteq \bigcup \mathcal{A}$ for every $A \in \mathcal{A}$ and hence $\bigcup \mathcal{A}$ is an upper bound of \mathcal{A} . If B is an upper bound of \mathcal{A} then $A \subseteq B$ for every $A \in \mathcal{A}$ and hence $\bigcup \mathcal{A} \subseteq B$. Therefore $\bigcup \mathcal{A}$ is the least upper bound.

In particular, $A \wedge B = A \cap B$ and $A \vee B = A \cup B$, so $(\mathcal{P}(S), \subseteq)$ is a lattice.

Consider the division partial order $|$ on the set of positive integers \mathbb{N}_+ and let A be a nonempty subset of \mathbb{N}_+ .

1. $\inf(A)$ is the *greatest common divisor* of A , usually denoted $\gcd(A)$ in this context.
2. If A is infinite then $\sup(A)$ does not exist. If A is finite then $\sup(A)$ is the *least common multiple* of A , usually denoted $\text{lcm}(A)$ in this context.

Suppose that S is a set and that $f : S \rightarrow S$. An element $z \in S$ is said to be a *fixed point* of f if $f(z) = z$.

The following result explores a basic fixed point theorem for a partially ordered set. The theorem is important in the study of [cardinality](#).

Suppose that \preceq is a partial order on a set S with the property that $\sup(A)$ exists for every $A \subseteq S$. If $f : S \rightarrow S$ is increasing, then f has a fixed point.

Proof.

Let $A = \{x \in S : x \preceq f(x)\}$ and let $z = \sup(A)$. If $x \in A$ then $x \preceq z$ so $x \preceq f(x) \preceq f(z)$. Hence $f(z)$ is an upper bound of A so $z \preceq f(z)$. But then $f(z) \preceq f(f(z))$ so $f(z) \in A$. Hence $f(z) \preceq z$. Therefore $f(z) = z$.

Note that the hypotheses of the theorem require that $\sup(\emptyset) = \min(S)$ exists. The set $A = \{x \in S : x \preceq f(x)\}$ is nonempty since $\min(S) \in A$.

If \preceq is a total order on a set S with the property that every nonempty subset of S has a minimum element, then S is said to be *well ordered* by \preceq . One of the most important examples is \mathbb{N}_+ , which is well ordered by the ordinary order \leq . On the other hand, the *well ordering principle*, which is equivalent to the [axiom of choice](#), states that every nonempty set can be well ordered.

Orders on Product Spaces

Suppose that S and T are sets with partial orders \preceq_S and \preceq_T respectively. Define the relation \preceq on $S \times T$ by $(x, y) \preceq (z, w)$ if and only if $x \preceq_S z$ and $y \preceq_T w$.

1. The relation \preceq is a partial order on $S \times T$, called, appropriately enough, the *product order*.
2. Suppose that $(S, \preceq_S) = (T, \preceq_T)$. If S has at least 2 elements, then \preceq is not a total order on S^2 .

Proof

Figure 1.4.1: The product order on \mathbb{R}^2 . The region shaded red is the set of points $\succeq (x, y)$. The region shaded blue is the set of points $\preceq (x, y)$. The region shaded white is the set of points that are not comparable with (x, y) .

Product order extends in a straightforward way to the Cartesian product of a finite or an infinite sequence of partially ordered spaces. For example, suppose that S_i is a set with partial order \preceq_i for each $i \in \{1, 2, \dots, n\}$, where $n \in \mathbb{N}_+$. The product order \preceq on the product set $S_1 \times S_2 \times \dots \times S_n$ is defined as follows: for $\mathbf{x} = (x_1, x_2, \dots, x_n)$ and $\mathbf{y} = (y_1, y_2, \dots, y_n)$ in the product set, $\mathbf{x} \preceq \mathbf{y}$ if and only if $x_i \preceq_i y_i$ for each $i \in \{1, 2, \dots, n\}$. We can generalize this further to arbitrary [product sets](#). Suppose that S_i is a set for each i in a nonempty (both otherwise arbitrary) index set I . Recall that

$$\prod_{i \in I} S_i = \left\{ x : x \text{ is a function from } I \text{ into } \bigcup_{i \in I} S_i \text{ such that } x(i) \in S_i \text{ for each } i \in I \right\} \quad (1.4.2)$$

To make the notation look more like a simple Cartesian product, we will write x_i instead of $x(i)$ for the value of a function x in the product set at $i \in I$.

Suppose that S_i is a set with partial order \preceq_i for each i in a nonempty index set I . Define the relation \preceq on $\prod_{i \in I} S_i$ by $x \preceq y$ if and only if $x_i \preceq_i y_i$ for each $i \in I$. Then \preceq is a partial order on the product set, known again as the *product order*.

Proof

In spite of the abstraction, the proof is perfectly straightforward. Suppose that $x, y, z \in \prod_{i \in I} S_i$.

1. $x_i \preceq_i x_i$ for every $i \in I$, and hence $x \preceq x$. Thus \preceq is reflexive.
2. Suppose that $x \preceq y$ and $y \preceq x$. Then $x_i \preceq_i y_i$ and $y_i \preceq_i x_i$ for each $i \in I$. Hence $x_i = y_i$ for each $i \in I$ and so $x = y$. Thus \preceq is antisymmetric.
3. Suppose that $x \preceq y$ and $y \preceq z$. Then $x_i \preceq_i y_i$ and $y_i \preceq_i z_i$ for each $i \in I$. Hence $x_i \preceq_i z_i$ for each $i \in I$, so $x \preceq z$. Thus \preceq is transitive.

Note again that no assumptions are made on the index set I , other than it be nonempty. In particular, no order is necessary on I . The next result gives a very different type of order on a product space.

Suppose again that S and T are sets with partial orders \preceq_S and \preceq_T respectively. Define the relation \preceq on $S \times T$ by $(x, y) \preceq (z, w)$ if and only if either $x \prec_S z$, or $x = z$ and $y \preceq_T w$.

1. The relation \preceq is a partial order on $S \times T$, called the *lexicographic order* or *dictionary order*.
2. If \preceq_S and \preceq_T are total orders on S and T , respectively, then \preceq is a total order on $S \times T$.

Proof

Figure 1.4.2: The lexicographic order on \mathbb{R}^2 . The region shaded red is the set of points $\succeq (x, y)$. The region shaded blue is the set of points $\preceq (x, y)$.

As with the product order, the lexicographic order can be generalized to a collection of partially ordered spaces. However, we need the index set to be totally ordered.

Suppose that S_i is a set with partial order \preceq_i for each i in a nonempty index set I . Suppose also that \leq is a total order on I . Define the relation \preceq on the product set $\prod_{i \in I} S_i$ as follows: $x \prec y$ if and only if there exists $j \in I$ such that $x_i = y_i$ if $i < j$ and $x_j \prec_j y_j$. Then

1. \preceq is a partial order on S , known again as the *lexicographic order*.
2. If \preceq_i is a total order for each $i \in I$, and I is well ordered by \leq , then \preceq is a total order on S .

Proof

1. By the result on [strong orders](#), we need to show that \prec is irreflexive and transitive. First, no $x \in \prod_{i \in I} S_i$ satisfies $x \prec x$ since $x_i = x_i$ for all $i \in I$. Hence \prec is irreflexive. Next, suppose that $x, y, z \in \prod_{i \in I} S_i$ and that $x \prec y$ and $y \prec z$. Then there exists $j \in I$ such that $x_i = y_i$ if $i < j$ and $x_j \prec_j y_j$. Similarly, there exists $k \in I$ such that $y_i = z_i$ if $i < k$ and $y_k \prec_k z_k$. Again, since I is totally ordered, either $j < k$ or $k < j$ or $j = k$. If $j < k$, then $x_i = y_i = z_i$ if $i < j$ and $x_j \prec_j y_j = z_j$. If $k < j$, then $x_i = y_i = z_i$ if $i < k$ and $x_k = y_k \prec_k z_k$. If $j = k$, then $x_i = y_i = z_i$ if $i < j$ and $x_j \prec_j y_j \prec_j z_j$. In all cases, $x \prec z$ so \prec is transitive.
2. Suppose now that \preceq_i is a total order on S_i for each $i \in I$ and that I is well ordered by \leq . Let $x, y \in \prod_{i \in I} S_i$ with $x \neq y$. Let $J = \{i \in I : x_i \neq y_i\}$. Then $J \neq \emptyset$ by assumption, and hence has a minimum element j . If $i < j$ then $i \notin J$ and hence $x_i = y_i$. On the other hand, $x_j \neq y_j$ since $j \in J$ and therefore, since \preceq_j is totally ordered, we must have either $x_j \prec_j y_j$ or $y_j \prec_j x_j$. In the first case, $x \prec y$ and in the second case $y \prec x$. Hence \preceq is totally ordered.

The term *lexicographic* comes from the way that we order words alphabetically: We look at the first letter; if these are different, we know how to order the words. If the first letters are the same, we look at the second letter; if these are different, we know how to order the words. We continue in this way until we find letters that are different, and we can order the words. In fact, the lexicographic order is sometimes referred to as the *first difference* order. Note also that if S_i is a set and \preceq_i a total order on S_i for $i \in I$, then by the well ordering principle, there exists a well ordering \leq of I , and hence there exists a lexicographic total order on the product space $\prod_{i \in I} S_i$. As a mathematical structure, the lexicographic order is not as obscure as you might think.

(\mathbb{R}, \leq) is isomorphic to the lexicographic product of (\mathbb{Z}, \leq) with $([0, 1), \leq)$, where \leq is the ordinary order for real numbers.

Proof

Every $x \in \mathbb{R}$ can be uniquely expressed in the form $x = n + t$ where $n = \lfloor x \rfloor \in \mathbb{Z}$ is the *integer part* and $t = x - n \in [0, 1)$ is the *remainder*. Thus $x \mapsto (n, t)$ is a one-to-one function from \mathbb{R} onto $\mathbb{Z} \times [0, 1)$. For example, 5.3 maps to (5, 0.3), while -6.7 maps to (-7, 0.3). Suppose that $x = m + s$, $y = n + t \in \mathbb{R}$, where of course $m, n \in \mathbb{Z}$ are the integer parts of x and y , respectively, and $s, t \in [0, 1)$ are the corresponding remainders. Then $x < y$ if and only if $m < n$ or $m = n$ and $s < t$. Again, to illustrate with *real* real numbers, we can tell that $5.3 < 7.8$ just by comparing the integer parts: $5 < 7$. We can ignore the remainders. On the other hand, to see that $6.4 < 6.7$ we need to compare the remainders: $0.4 < 0.7$ since the integer parts are the same.

Limits of Sequences of Real Numbers

Suppose that (a_1, a_2, \dots) is a sequence of real numbers.

The sequence $\inf\{a_n, a_{n+1}, \dots\}$ is increasing in $n \in \mathbb{N}_+$.

Since the sequence of infimums in the last result is increasing, the limit exists in $\mathbb{R} \cup \{\infty\}$, and is called the *limit inferior* of the original sequence:

$$\liminf_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} \inf\{a_n, a_{n+1}, \dots\} \quad (1.4.3)$$

The sequence $\sup\{a_n, a_{n+1}, \dots\}$ is decreasing in $n \in \mathbb{N}_+$.

Since the the sequence of supremums in the last result is decreasing, the limit exists in $\mathbb{R} \cup \{-\infty\}$, and is called the *limit superior* of the original sequence:

$$\limsup_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} \sup\{a_n, a_{n+1}, \dots\} \quad (1.4.4)$$

Note that $\liminf_{n \rightarrow \infty} a_n \leq \limsup_{n \rightarrow \infty} a_n$ and equality holds if and only if $\lim_{n \rightarrow \infty} a_n$ exists (and is the common value).

Vector Spaces of Functions

Suppose that S is a nonempty set, and recall that the set \mathcal{V} of functions $f : S \rightarrow \mathbb{R}$ is a vector space, under the usual pointwise definition of addition and scalar multiplication. As noted in (9), \mathcal{V} is also a partial ordered set, under the pointwise partial order: $f \preceq g$ if and only if $f(x) \leq g(x)$ for all $x \in S$. Consistent with the definitions (19), $f \in \mathcal{V}$ is *bounded* if there exists $C \in (0, \infty)$ such that $|f(x)| \leq C$ for all $x \in S$. Now let \mathcal{U} denote the set of bounded functions $f : S \rightarrow \mathbb{R}$, and for $f \in \mathcal{U}$ define

$$\|f\| = \sup\{|f(x)| : x \in S\} \quad (1.4.5)$$

\mathcal{U} is a vector subspace of \mathcal{V} and $\|\cdot\|$ is a norm on \mathcal{U} .

Proof

To show that \mathcal{U} is a subspace, we just have to note that it is closed under addition and scalar multiplication. That is, if $f, g : S \rightarrow \mathbb{R}$ are bounded, and if $c \in \mathbb{R}$, then $f + g$ and cf are bounded. Next we show that $\|\cdot\|$ satisfies the axioms of a norm. Again, let $f, g \in \mathcal{U}$ and $c \in \mathbb{R}$

1. Clearly $\|f\| \geq 0$ and $\|f\| = 0$ if and only if $f(x) = 0$ for all $x \in S$ if and only if $f = \mathbf{0}$, the zero function on S .
2. $\|cf\| = \sup\{|cf(x)| : x \in S\} = |c| \sup\{|f(x)| : x \in S\} = |c| \|f\|$
3. By the usual triangle inequality on \mathbb{R} , $|f(x) + g(x)| \leq |f(x)| + |g(x)|$ for $x \in S$. Hence

$$\sup\{|f(x) + g(x)| : x \in S\} \leq \sup\{|f(x)| + |g(x)| : x \in S\} \leq \sup\{|f(x)| : x \in S\} + \sup\{|g(x)| : x \in S\} \quad (1.4.6)$$

That is, $\|f + g\| \leq \|f\| + \|g\|$.

Recall that part (a) is the *positive property*, part (b) is the *scaling property*, and part (c) is the *triangle inequality*.

Appropriately enough, $\|\cdot\|$ is called the *supremum norm* on \mathcal{U} . Vector spaces of bounded, real-valued functions, with the supremum norm are especially important in probability and random processes. We will return to this discussion again in the advanced sections on metric spaces and measure theory.

Computational Exercises

Let $S = \{2, 3, 4, 6, 12\}$.

1. Sketch the Hasse graph corresponding to the ordinary order \leq on S .
2. Sketch the Hasse graph corresponding to the division partial order $|$ on S .

Answer

1.

The Hasse graph of (S, \leq)

 Hasse graph

2.

The Hasse graph of $(S, |)$

 Hasse graph

Consider the ordinary order \leq on the set of real numbers \mathbb{R} , and let $A = [a, b)$ where $a < b$. Find each of the following that exist:

1. The set of minimal elements of A
2. The set of maximal elements of A
3. $\min(A)$
4. $\max(A)$
5. The set of lower bounds of A
6. The set of upper bounds of A
7. $\inf(A)$
8. $\sup(A)$

Answer

1. $\{a\}$
2. \emptyset
3. a
4. Does not exist
5. $(-\infty, a]$
6. $[b, \infty)$
7. a
8. b

Again consider the division partial order $|$ on the set of positive integers \mathbb{N}_+ and let $A = \{2, 3, 4, 6, 12\}$. Find each of the following that exist:

1. The set of minimal elements of A
2. The set of maximal elements of A
3. $\min(A)$
4. $\max(A)$
5. The set of lower bounds of A
6. The set of upper bounds of A
7. $\inf(A)$
8. $\sup(A)$.

Answer

1. $\{2, 3\}$
2. $\{12\}$
3. Does not exist
4. 12
5. $\{1\}$
6. $\{12, 24, 36, \dots\}$

7. 1
8. 12

Let $S = \{a, b, c\}$.

1. Give $\mathcal{P}(S)$ in list form.
2. Describe the Hasse graph of $(\mathcal{P}(S), \subseteq)$

Answer

1. $\mathcal{P}(S) = \{\emptyset, \{a\}, \{b\}, \{c\}, \{a, b\}, \{a, c\}, \{b, c\}, S\}$
2. For $A \in \mathcal{P}(S)$ and $x \in S \setminus A$, there is a directed edge from A to $A \cup \{x\}$

Note that the Hasse graph of \supseteq looks the same as the graph of \subseteq , except for the labels on the vertices. This symmetry is because of the complement relationship.

Let $S = \{a, b, c, d\}$.

1. Give $\mathcal{P}(S)$ in list form.
2. Describe the Hasse graph of $(\mathcal{P}(S), \subseteq)$

Answer

1. $\mathcal{P}(S) = \{\emptyset, \{a\}, \{b\}, \{c\}, \{d\}, \{a, b\}, \{a, c\}, \{a, d\}, \{b, c\}, \{b, d\}, \{c, d\}, \{a, b, c\}, \{a, b, d\}, \{a, c, d\}, \{b, c, d\}, S\}$
2. For $A \in \mathcal{P}(S)$ and $x \in S \setminus A$, there is a directed edge from A to $A \cup \{x\}$

Note again that the Hasse graph of \supseteq looks the same as the graph of \subseteq , except for the labels on the vertices. This symmetry is because the complement relationship.

Suppose that A and B are subsets of a universal set S . Let \mathcal{A} denote the collection of the 16 subsets of S that can be constructed from A and B using the set operations. Show that (\mathcal{A}, \subseteq) is isomorphic to the partially ordered set in the previous exercise. Use the Venn diagram app to help.

Proof

Let $a = A \cap B$, $b = A \cap B^c$, $c = A^c \cap B$, $d = A^c \cap B^c$. Our basic assumption is that A and B are in “general position”, so that a, b, c, d are distinct and nonempty. Note also that $\{a, b, c, d\}$ partitions S . Now, map each subset \mathcal{S} of $\{a, b, c, d\}$ to $\bigcup \mathcal{S}$. This function is an isomorphism from \mathcal{S} to \mathcal{A} . That is, for \mathcal{S} and \mathcal{T} subsets of $\{a, b, c, d\}$, $\mathcal{S} \subseteq \mathcal{T}$ if and only if $\bigcup \mathcal{S} \subseteq \bigcup \mathcal{T}$.

1.5: Equivalence Relations

Basic Theory

Definitions

A relation \approx on a nonempty set S that is reflexive, symmetric, and transitive is an *equivalence relation* on S . Thus, for all $x, y, z \in S$,

1. $x \approx x$, the *reflexive property*.
2. If $x \approx y$ then $y \approx x$, the *symmetric property*.
3. If $x \approx y$ and $y \approx z$ then $x \approx z$, the *transitive property*.

As the name and notation suggest, an equivalence relation is intended to define a type of equivalence among the elements of S . Like [partial orders](#), equivalence relations occur naturally in most areas of mathematics, including probability.

Suppose that \approx is an equivalence relation on S . The *equivalence class* of an element $x \in S$ is the set of all elements that are equivalent to x , and is denoted

$$[x] = \{y \in S : y \approx x\} \quad (1.5.1)$$

Results

The most important result is that an equivalence relation on a set S defines a partition of S , by means of the equivalence classes.

Suppose that \approx is an equivalence relation on a set S .

1. If $x \approx y$ then $[x] = [y]$.
2. If $x \not\approx y$ then $[x] \cap [y] = \emptyset$.
3. The collection of (distinct) equivalence classes is a partition of S into nonempty sets.

Proof

1. Suppose that $x \approx y$. If $u \in [x]$ then $u \approx x$ and hence $u \approx y$ by the transitive property. Hence $u \in [y]$. Similarly, if $u \in [y]$ then $u \approx y$. But $y \approx x$ by the symmetric property, and hence $u \approx x$ by the transitive property. Hence $u \in [x]$.
2. Suppose that $x \not\approx y$. If $u \in [x] \cap [y]$, then $u \in [x]$ and $u \in [y]$, so $u \approx x$ and $u \approx y$. But then $x \approx u$ by the symmetric property, and then $x \approx y$ by the transitive property. This is a contradiction, so $[x] \cap [y] = \emptyset$.
3. From (a) and (b), the (distinct) equivalence classes are disjoint. If $x \in S$, then $x \approx x$ by the reflexive property, and hence $x \in [x]$. Therefore $\bigcup_{x \in S} [x] = S$.

Sometimes the set \mathcal{S} of equivalence classes is denoted S/\approx . The idea is that the equivalence classes are new “objects” obtained by “identifying” elements in S that are equivalent. Conversely, every partition of a set defines an equivalence relation on the set.

Suppose that \mathcal{S} is a collection of nonempty sets that partition a given set S . Define the relation \approx on S by $x \approx y$ if and only if $x \in A$ and $y \in A$ for some $A \in \mathcal{S}$.

1. \approx is an equivalence relation.
2. \mathcal{S} is the set of equivalence classes.

Proof

1. If $x \in S$, then $x \in A$ for some $A \in \mathcal{S}$, since \mathcal{S} partitions S . Hence $x \approx x$, and so the reflexive property holds. Next, \approx is trivially symmetric by definition. Finally, suppose that $x \approx y$ and $y \approx z$. Then $x, y \in A$ for some $A \in \mathcal{S}$ and $y, z \in B$ for some $B \in \mathcal{S}$. But then $y \in A \cap B$. The sets in \mathcal{S} are disjoint, so $A = B$. Hence $x, z \in A$, so $x \approx z$. Thus \approx is transitive.
2. If $x \in S$, then $x \in A$ for a unique $A \in \mathcal{S}$, and then by definition, $[x] = A$.

Figure 1.5.1: A partition of S . Any two points in the same partition set are equivalent.

Sometimes the equivalence relation \approx associated with a given partition \mathcal{S} is denoted S/\mathcal{S} . The idea, of course, is that elements in the same set of the partition are equivalent.

The process of forming a partition from an equivalence relation, and the process of forming an equivalence relation from a partition are inverses of each other.

1. If we start with an equivalence relation \approx on S , form the associated partition, and then construct the equivalence relation associated with the partition, then we end up with the original equivalence relation. In modular notation, $S/(S/\approx)$ is the same as \approx .
2. If we start with a partition \mathcal{S} of S , form the associated equivalence relation, and then form the partition associated with the equivalence relation, then we end up with the original partition. In modular notation, $S/(S/\mathcal{S})$ is the same as \mathcal{S} .

Suppose that S is a nonempty set. The most basic equivalence relation on S is the *equality relation* $=$. In this case $[x] = \{x\}$ for each $x \in S$. At the other extreme is the *trivial relation* \approx defined by $x \approx y$ for all $x, y \in S$. In this case S is the only equivalence class.

Every function f defines an equivalence relation on its domain, known as the *equivalence relation associated with f* . Moreover, the equivalence classes have a simple description in terms of the inverse images of f .

Suppose that $f : S \rightarrow T$. Define the relation \approx on S by $x \approx y$ if and only if $f(x) = f(y)$.

1. The relation \approx is an equivalence relation on S .
2. The set of equivalence classes is $\mathcal{S} = \{f^{-1}\{t\} : t \in \text{range}(f)\}$.
3. The function $F : \mathcal{S} \rightarrow T$ defined by $F([x]) = f(x)$ is well defined and is one-to-one.

Proof

1. If $x \in S$ then trivially $f(x) = f(x)$, so $x \approx x$. Hence \approx is reflexive. If $x \approx y$ then $f(x) = f(y)$ so trivially $f(y) = f(x)$ and hence $y \approx x$. Thus \approx is symmetric. If $x \approx y$ and $y \approx z$ then $f(x) = f(y)$ and $f(y) = f(z)$, so trivially $f(x) = f(z)$ and so $x \approx z$. Hence \approx is transitive.
2. Recall that $t \in \text{range}(f)$ if and only if $f(x) = t$ for some $x \in S$. Then by definition, $[x] = f^{-1}\{t\} = \{y \in S : f(y) = t\} = \{y \in S : f(y) = f(x)\}$
3. From (2), $[x] = [y]$ if and only if $x \approx y$ if and only if $f(x) = f(y)$. This shows both that F is well defined, and that F is one-to-one.

Figure 1.5.2: The equivalence relation on S associated with $f : S \rightarrow T$

Suppose again that $f : S \rightarrow T$.

1. If f is one-to-one then the equivalence relation associated with f is the equality relation, and hence $[x] = \{x\}$ for each $x \in S$.
2. If f is a constant function then the equivalence relation associated with f is the trivial relation, and hence S is the only equivalence class.

Proof

1. If f is one-to-one, then $x \approx y$ if and only if $f(x) = f(y)$ if and only if $x = y$.
2. If f is constant on S then $f(x) = f(y)$ and hence $x \approx y$ for all $x, y \in S$.

Equivalence relations associated with functions are universal: every equivalence relation is of this form:

Suppose that \approx is an equivalence relation on a set S . Define $f : S \rightarrow \mathcal{P}(S)$ by $f(x) = [x]$. Then \approx is the equivalence relation associated with f .

Proof

From (6), $x \approx y$ if and only if $[x] = [y]$ if and only if $f(x) = f(y)$.

The intersection of two equivalence relations is another equivalence relation.

Suppose that \approx and \cong are equivalence relations on a set S . Let \equiv denote the intersection of \approx and \cong (thought of as subsets of $S \times S$). Equivalently, $x \equiv y$ if and only if $x \approx y$ and $x \cong y$.

1. \equiv is an equivalence relation on S .

2. $[x]_{\equiv} = [x]_{\approx} \cap [x]_{\cong}$.

Suppose that we have a relation that is reflexive and transitive, but fails to be a partial order because it's not anti-symmetric. The relation and its inverse naturally lead to an equivalence relation, and then in turn, the original relation defines a true partial order on the equivalence classes. This is a common construction, and the details are given in the next theorem.

Suppose that \preceq is a relation on a set S that is reflexive and transitive. Define the relation \approx on S by $x \approx y$ if and only if $x \preceq y$ and $y \preceq x$.

1. \approx is an equivalence relation on S .

2. If A and B are equivalence classes and $x \preceq y$ for some $x \in A$ and $y \in B$, then $u \preceq v$ for all $u \in A$ and $v \in B$.

3. Define the relation \preceq on the collection of equivalence classes \mathcal{S} by $A \preceq B$ if and only if $x \preceq y$ for some (and hence all) $x \in A$ and $y \in B$. Then \preceq is a partial order on \mathcal{S} .

Proof

1. If $x \in S$ then $x \preceq x$ since \preceq is reflexive. Hence $x \approx x$, so \approx is reflexive. Clearly \approx is symmetric by the symmetry of the definition. Suppose that $x \approx y$ and $y \approx z$. Then $x \preceq y$, $y \preceq z$, $z \preceq y$ and $y \preceq x$. Hence $x \preceq z$ and $z \preceq x$ since \preceq is transitive. Therefore $x \approx z$ so \approx is transitive.

2. Suppose that A and B are equivalence classes of \approx and that $x \preceq y$ for some $x \in A$ and $y \in B$. If $u \in A$ and $v \in B$, then $x \approx u$ and $y \approx v$. Therefore $u \preceq x$ and $y \preceq v$. By transitivity, $u \preceq v$.

3. Suppose that $A \in \mathcal{S}$. If $x, y \in A$ then $x \approx y$ and hence $x \preceq y$. Therefore $A \preceq A$ and so \preceq is reflexive. Next suppose that $A, B \in \mathcal{S}$ and that $A \preceq B$ and $B \preceq A$. If $x \in A$ and $y \in B$ then $x \preceq y$ and $y \preceq x$. Hence $x \approx y$ so $A = B$. Therefore \preceq is antisymmetric. Finally, suppose that $A, B, C \in \mathcal{S}$ and that $A \preceq B$ and $B \preceq C$. Note that $B \neq \emptyset$ so let $y \in B$. If $x \in A$, $z \in C$ then $x \preceq y$ and $y \preceq z$. Hence $x \preceq z$ and therefore $A \preceq C$. So \preceq is transitive.

A prime example of the construction in the previous theorem occurs when we have a function whose range space is partially ordered. We can construct a partial order on the equivalence classes in the domain that are associated with the function.

Suppose that S and T are sets and that \preceq_T is a partial order on T . Suppose also that $f : S \rightarrow T$. Define the relation \preceq_S on S by $x \preceq_S y$ if and only if $f(x) \preceq_T f(y)$.

1. \preceq_S is reflexive and transitive.

2. The equivalence relation on S constructed in (10) is the equivalence relation associated with f , as in (6).

3. \preceq_S can be extended to a partial order on the equivalence classes corresponding to f .

Proof

1. If $x \in S$ then $f(x) \preceq_T f(x)$ since \preceq_T is reflexive, and hence $x \preceq_S x$. Thus \preceq_S is reflexive. Suppose that $x, y, z \in S$ and that $x \preceq_S y$ and $y \preceq_S z$. Then $f(x) \preceq_T f(y)$ and $f(y) \preceq_T f(z)$. Hence $f(x) \preceq_T f(z)$ since \preceq_T is transitive. Thus \preceq_S is transitive.

2. For the equivalence relation \approx on S constructed in (10), $x \approx y$ if and only if $x \preceq_S y$ and $y \preceq_S x$ if and only if $f(x) \preceq_T f(y)$ and $f(y) \preceq_T f(x)$ if and only if $f(x) = f(y)$, since \preceq_T is antisymmetric. Thus \approx is the equivalence relation associated with f .

3. This follows immediately from (10) and parts (a) and (b). If $u, v \in \text{range}(f)$, then $f^{-1}(\{u\}) \preceq_S f^{-1}(\{v\})$ if and only if $u \preceq_T v$.

Examples and Applications

Simple functions

Give the equivalence classes explicitly for the functions from \mathbb{R} into \mathbb{R} defined below:

1. $f(x) = x^2$.
2. $g(x) = \lfloor x \rfloor$.
3. $h(x) = \sin(x)$.

Answer

1. $[x] = \{x, -x\}$
2. $[x] = [\lfloor x \rfloor, \lfloor x \rfloor + 1)$
3. $[x] = \{x + 2n\pi : n \in \mathbb{Z}\} \cup \{(2n+1)\pi - x : n \in \mathbb{Z}\}$

Calculus

Suppose that I is a fixed interval of \mathbb{R} , and that S is the set of differentiable functions from I into \mathbb{R} . Consider the equivalence relation associated with the derivative operator D on S , so that $D(f) = f'$. For $f \in S$, give a simple description of $[f]$.

Answer

$$[f] = \{f + c : c \in \mathbb{R}\}$$

Congruence

Recall the *division relation* $|$ from \mathbb{N}_+ to \mathbb{Z} : For $d \in \mathbb{N}_+$ and $n \in \mathbb{Z}$, $d | n$ means that $n = kd$ for some $k \in \mathbb{Z}$. In words, d divides n or equivalently n is a multiple of d . In the previous section, we showed that $|$ is a partial order on \mathbb{N}_+ .

Fix $d \in \mathbb{N}_+$.

1. Define the relation \equiv_d on \mathbb{Z} by $m \equiv_d n$ if and only if $d | (n - m)$. The relation \equiv_d is known as *congruence modulo d* .
2. Let $r_d : \mathbb{Z} \rightarrow \{0, 1, \dots, d-1\}$ be defined so that $r_d(n)$ is the remainder when n is divided by d .

Recall that by the *Euclidean division theorem*, named for Euclid of course, $n \in \mathbb{Z}$ can be written uniquely in the form $n = kd + q$ where $k \in \mathbb{Z}$ and $q \in \{0, 1, \dots, d-1\}$, and then $r_d(n) = q$.

Congruence modulo d .

1. \equiv_d is the equivalence relation associated with the function r_d .
2. There are d distinct equivalence classes, given by $[q]_d = \{q + kd : k \in \mathbb{Z}\}$ for $q \in \{0, 1, \dots, d-1\}$.

Proof

1. Recall that for the equivalence relation associated with r_d , integers m and n are equivalent if and only if $r_d(m) = r_d(n)$. By the division theorem, $m = jd + p$ and $n = kd + q$, where $j, k \in \mathbb{Z}$ and $p, q \in \{0, 1, \dots, d-1\}$, and these representations are unique. Thus $n - m = (k - j)d + (q - p)$, and so $m \equiv_d n$ if and only if $d | (n - m)$ if and only if $p = q$ if and only if $r_d(m) = r_d(n)$.
2. Recall that the equivalence classes are $r_d^{-1}\{q\}$ for $q \in \text{range}(r_d) = \{0, 1, \dots, d-1\}$. By the division theorem, $r_d^{-1}\{q\} = \{kd + q : k \in \mathbb{Z}\}$.

Explicitly give the equivalence classes for \equiv_4 , congruence mod 4.

Answer

- $[0]_4 = \{0, 4, 8, 12, \dots\} \cup \{-4, -8, -12, -16, \dots\}$
- $[1]_4 = \{1, 5, 9, 13, \dots\} \cup \{-3, -7, -11, -15, \dots\}$
- $[2]_4 = \{2, 6, 10, 14, \dots\} \cup \{-2, -6, -10, -14, \dots\}$
- $[3]_4 = \{3, 7, 11, 15, \dots\} \cup \{-1, -5, -9, -13, \dots\}$

Linear Algebra

Linear algebra provides several examples of important and interesting equivalence relations. To set the stage, let $\mathbb{R}^{m \times n}$ denote the set of $m \times n$ matrices with real entries, for $m, n \in \mathbb{N}_+$.

Recall that the following are *row operations* on a matrix:

1. Multiply a row by a non-zero real number.
2. Interchange two rows.
3. Add a multiple of a row to another row.

Row operations are essential for inverting matrices and solving systems of linear equations.

Matrices $A, B \in \mathbb{R}^{m \times n}$ are *row equivalent* if A can be transformed into B by a finite sequence of row operations. Row equivalence is an equivalence relation on $\mathbb{R}^{m \times n}$.

Proof.

If $A \in \mathbb{R}^{m \times n}$, then A is row equivalent to itself: we can simply do nothing, or if you prefer, we can multiply the first row of A by 1. For symmetry, the key is that each row operation can be reversed by another row operation: multiplying a row by $c \neq 0$ is reversed by multiplying the same row of the resulting matrix by $1/c$. Interchanging two rows is reversed by interchanging the same two rows of the resulting matrix. Adding c times row i to row j is reversed by adding $-c$ times row i to row j in the resulting matrix. Thus, if we can transform A into B by a finite sequence of row operations, then we can transform B into A by applying the reversed row operations in the reverse order. Transitivity is clear: If we can transform A into B by a sequence of row operations and B into C by another sequence of row operations, then we can transform A into C by putting the two sequences together.

Our next relation involves similarity, which is very important in the study of linear transformations, change of basis, and the theory of eigenvalues and eigenvectors.

Matrices $A, B \in \mathbb{R}^{n \times n}$ are *similar* if there exists an invertible $P \in \mathbb{R}^{n \times n}$ such that $P^{-1}AP = B$. Similarity is an equivalence relation on $\mathbb{R}^{n \times n}$.

Proof

If $A \in \mathbb{R}^{n \times n}$ then $A = I^{-1}AI$, where I is the $n \times n$ identity matrix, so A is similar to itself. Suppose that $A, B \in \mathbb{R}^{n \times n}$ and that A is similar to B so that $B = P^{-1}AP$ for some invertible $P \in \mathbb{R}^{n \times n}$. Then $A = PBP^{-1} = (P^{-1})^{-1}BP^{-1}$ so B is similar to A . Finally, suppose that $A, B, C \in \mathbb{R}^{n \times n}$ and that A is similar to B and that B is similar to C . Then $B = P^{-1}AP$ and $C = Q^{-1}BQ$ for some invertible $P, Q \in \mathbb{R}^{n \times n}$. Then $C = Q^{-1}P^{-1}APQ = (PQ)^{-1}A(PQ)$, so A is similar to C .

Next recall that for $A \in \mathbb{R}^{m \times n}$, the *transpose* of A is the matrix $A^T \in \mathbb{R}^{n \times m}$ with the property that (i, j) entry of A is the (j, i) entry of A^T , for $i, j \in \{1, 2, \dots, m\}$. Simply stated, A^T is the matrix whose rows are the columns of A . For the theorem that follows, we need to remember that $(AB)^T = B^T A^T$ for $A \in \mathbb{R}^{m \times n}$ and $B \in \mathbb{R}^{n \times k}$, and $(A^T)^{-1} = (A^{-1})^T$ if $A \in \mathbb{R}^{n \times n}$ is invertible.

Matrices $A, B \in \mathbb{R}^{n \times n}$ are *congruent* if there exists an invertible $P \in \mathbb{R}^{n \times n}$ such that $B = P^T A P$. Congruence is an equivalence relation on $\mathbb{R}^{n \times n}$.

Proof

If $A \in \mathbb{R}^{n \times n}$ then $A = I^T A I$, where again I is the $n \times n$ identity matrix, so A is congruent to itself. Suppose that $A, B \in \mathbb{R}^{n \times n}$ and that A is congruent to B so that $B = P^T A P$ for some invertible $P \in \mathbb{R}^{n \times n}$. Then $A = (P^T)^{-1} B P^{-1} = (P^{-1})^T B P^{-1}$ so B is congruent to A . Finally, suppose that $A, B, C \in \mathbb{R}^{n \times n}$ and that A is congruent to B and that B is congruent to C . Then $B = P^T A P$ and $C = Q^T B Q$ for some invertible $P, Q \in \mathbb{R}^{n \times n}$. Then $C = Q^T P^T A P Q = (PQ)^T A (PQ)$, so A is congruent to C .

Congruence is important in the study of orthogonal matrices and change of basis. Of course, the term *congruence* applied to matrices should not be confused with the same term applied to integers.

Number Systems

Equivalence relations play an important role in the construction of complex mathematical structures from simpler ones. Often the objects in the new structure are equivalence classes of objects constructed from the simpler structures, modulo an equivalence relation that captures the essential properties of the new objects.

The construction of number systems is a prime example of this general idea. The next exercise explores the construction of rational numbers from integers.

Define a relation \approx on $\mathbb{Z} \times \mathbb{N}_+$ by $(j, k) \approx (m, n)$ if and only if $jn = km$.

1. \approx is an equivalence relation.
2. Define $\frac{m}{n} = [(m, n)]$, the equivalence class generated by (m, n) , for $m \in \mathbb{Z}$ and $n \in \mathbb{N}_+$. This definition captures the essential properties of the rational numbers.

Proof

1. For $(m, n) \in \mathbb{Z} \times \mathbb{N}_+$, $mn = nm$ of course, so $(m, n) \approx (m, n)$. Hence \approx is reflexive. If $(j, k), (m, n) \in \mathbb{Z} \times \mathbb{N}_+$ and $(j, k) \approx (m, n)$, then $jn = km$ so trivially $mk = nj$, and hence $(m, n) \approx (j, k)$. Thus \approx is symmetric. Finally, suppose that $(j, k), (m, n), (p, q) \in \mathbb{Z} \times \mathbb{N}_+$ and that $(j, k) \approx (m, n)$ and $(m, n) \approx (p, q)$. Then $jn = km$ and $mq = np$, so $jnp = kmp$ which implies $jmq = kmp$, and so $jq = kp$. Hence $(j, k) \approx (p, q)$ so \approx is transitive.
2. Suppose that $\frac{j}{k}$ and $\frac{m}{n}$ are rational numbers in the usual, informal sense, where $j, m \in \mathbb{Z}$ and $k, n \in \mathbb{N}_+$. Then $\frac{j}{k} = \frac{m}{n}$ if and only if $jn = km$ if and only if $(j, k) \approx (m, n)$, so it makes sense to define $\frac{m}{n}$ as the equivalence class generated by (m, n) . Addition and multiplication are defined in the usual way: if $(j, k), (m, n) \in \mathbb{Z} \times \mathbb{N}_+$ then

$$\frac{j}{k} + \frac{m}{n} = \frac{jn + mk}{kn}, \quad \frac{j}{k} \cdot \frac{m}{n} = \frac{jm}{kn} \quad (1.5.2)$$

The definitions are consistent; that is they do not depend on the particular representations of the equivalence classes.

This page titled [1.5: Equivalence Relations](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

1.6: Cardinality

Basic Theory

Definitions

Suppose that \mathcal{S} is a non-empty collection of sets. We define a relation \approx on \mathcal{S} by $A \approx B$ if and only if there exists a one-to-one function f from A onto B . The relation \approx is an equivalence relation on \mathcal{S} . That is, for all $A, B, C \in \mathcal{S}$,

1. $A \approx A$, the reflexive property
2. If $A \approx B$ then $B \approx A$, the symmetric property
3. If $A \approx B$ and $B \approx C$ then $A \approx C$, the transitive property

Proof

1. The identity function I_A on A , given by $I_A(x) = x$ for $x \in A$, maps A one-to-one onto A . Hence $A \approx A$.
2. If $A \approx B$ then there exists a one-to-one function f from A onto B . But then f^{-1} is a one-to-one function from B onto A , so $B \approx A$.
3. Suppose that $A \approx B$ and $B \approx C$. Then there exists a one-to-one function f from A onto B and a one-to-one function g from B onto C . But then $g \circ f$ is a one-to-one function from A onto C , so $A \approx C$.

A one-to-one function f from A onto B is sometimes called a *bijection*. Thus if $A \approx B$ then A and B are in *one-to-one* correspondence and are said to have the same *cardinality*. The equivalence classes under this equivalence relation capture the notion of having the same number of elements.

Let $\mathbb{N}_0 = \emptyset$, and for $k \in \mathbb{N}_+$, let $\mathbb{N}_k = \{0, 1, \dots, k-1\}$. As always, $\mathbb{N} = \{0, 1, 2, \dots\}$ is the set of all natural numbers.

Suppose that A is a set.

1. A is *finite* if $A \approx \mathbb{N}_k$ for some $k \in \mathbb{N}$, in which case k is the cardinality of A , and we write $\#(A) = k$.
2. A is *infinite* if A is not finite.
3. A is *countably infinite* if $A \approx \mathbb{N}$.
4. A is *countable* if A is finite or countably infinite.
5. A is *uncountable* if A is not countable.

In part (a), think of \mathbb{N}_k as a *reference set* with k elements; any other set with k elements must be equivalent to this one. We will study the cardinality of finite sets in the next two sections on Counting Measure and Combinatorial Structures. In this section, we will concentrate primarily on infinite sets. In part (d), a countable set is one that can be *enumerated* or *counted* by putting the elements into one-to-one correspondence with \mathbb{N}_k for some $k \in \mathbb{N}$ or with all of \mathbb{N} . An uncountable set is one that cannot be so counted. Countable sets play a special role in probability theory, as in many other branches of mathematics. Apriori, it's not clear that there *are* uncountable sets, but we will soon see examples.

Preliminary Examples

If S is a set, recall that $\mathcal{P}(S)$ denotes the power set of S (the set of all subsets of S). If A and B are sets, then A^B is the set of all functions from B into A . In particular, $\{0, 1\}^S$ denotes the set of functions from S into $\{0, 1\}$.

If S is a set then $\mathcal{P}(S) \approx \{0, 1\}^S$.

Proof

The mapping that takes a set $A \in \mathcal{P}(S)$ into its indicator function $\mathbf{1}_A \in \{0, 1\}^S$ is one-to-one and onto. Specifically, if $A, B \in \mathcal{P}(S)$ and $\mathbf{1}_A = \mathbf{1}_B$, then $A = B$, so the mapping is one-to-one. On the other hand, if $f \in \{0, 1\}^S$ then $f = \mathbf{1}_A$ where $A = \{x \in S : f(x) = 1\}$. Hence the mapping is onto.

Next are some examples of countably infinite sets.

The following sets are countably infinite:

1. The set of even natural numbers $E = \{0, 2, 4, \dots\}$
2. The set of integers \mathbb{Z}

Proof

1. The function $f: \mathbb{N} \rightarrow E$ given by $f(n) = 2n$ is one-to-one and onto.
2. The function $g: \mathbb{N} \rightarrow \mathbb{Z}$ given by $g(n) = \frac{n}{2}$ if n is even and $g(n) = -\frac{n+1}{2}$ if n is odd, is one-to-one and onto.

At one level, it might seem that E has only half as many elements as \mathbb{N} while \mathbb{Z} has twice as many elements as \mathbb{N} . as the previous result shows, that point of view is incorrect: \mathbb{N} , E , and \mathbb{Z} all have the same cardinality (and are countably infinite). The next example shows that there are indeed uncountable sets.

If A is a set with at least two elements then $S = A^{\mathbb{N}}$, the set of all functions from \mathbb{N} into A , is uncountable.

Proof

The proof is by contradiction, and uses a nice trick known as the *diagonalization method*. Suppose that S is countably infinite (it's clearly not finite), so that the elements of S can be enumerated: $S = \{f_0, f_1, f_2, \dots\}$. Let a and b denote distinct elements of A and define $g: \mathbb{N} \rightarrow A$ by $g(n) = b$ if $f_n(n) = a$ and $g(n) = a$ if $f_n(n) \neq a$. Note that $g \neq f_n$ for each $n \in \mathbb{N}$, so $g \notin S$. This contradicts the fact that S is the set of *all* functions from \mathbb{N} into A .

Subsets of Infinite Sets

Surely a set must be at least as large as any of its subsets, in terms of cardinality. On the other hand, by example (4), the set of natural numbers \mathbb{N} , the set of even natural numbers E and the set of integers \mathbb{Z} all have exactly the same cardinality, even though $E \subset \mathbb{N} \subset \mathbb{Z}$. In this subsection, we will explore some interesting and somewhat paradoxical results that relate to subsets of infinite sets. Along the way, we will see that the countable infinity is the “smallest” of the infinities.

If S is an infinite set then S has a countable infinite subset.

Proof

Select $a_0 \in S$. It's possible to do this since S is infinite and therefore nonempty. Inductively, having chosen $\{a_0, a_1, \dots, a_{k-1}\} \subseteq S$, select $a_k \in S \setminus \{a_0, a_1, \dots, a_{k-1}\}$. Again, it's possible to do this since S is not finite. Manifestly, $\{a_0, a_1, \dots\}$ is a countably infinite subset of S .

A set S is infinite if and only if S is equivalent to a proper subset of S .

Proof

If S is finite, then S is not equivalent to a proper subset by the “pigeonhole principle”. If S is infinite, then S has countably infinite subset $\{a_0, a_1, a_2, \dots\}$ by the previous result. Define the function $f: S \rightarrow S$ by $f(a_n) = a_{2n}$ for $n \in \mathbb{N}$ and $f(x) = x$ for $x \in S \setminus \{a_0, a_1, a_2, \dots\}$. Then f maps S one-to-one onto $S \setminus \{a_1, a_3, a_5, \dots\}$.

When S was infinite in the proof of the previous result, not only did we map S one-to-one onto a proper subset, we actually threw away a countably infinite subset and still maintained equivalence. Similarly, we can *add* a countably infinite set to an infinite set S without changing the cardinality.

If S is an infinite set and B is a countable set, then $S \approx S \cup B$.

Proof

Consider the most extreme case where B is countably infinite and disjoint from S . Then S has a countably infinite subset $A = \{a_0, a_1, a_2, \dots\}$ by the result above, and B can be enumerated, so $B = \{b_0, b_1, b_2, \dots\}$. Define the function $f: S \rightarrow S \cup B$ by $f(a_n) = a_{n/2}$ if n is even, $f(a_n) = b_{(n-1)/2}$ if n is odd, and $f(x) = x$ if $x \in S \setminus \{a_0, a_1, a_2, \dots\}$. Then f maps S one-to-one onto $S \cup B$.

In particular, if S is uncountable and B is countable then $S \cup B$ and $S \setminus B$ have the same cardinality as S , and in particular are uncountable. In terms of the dichotomies *finite-infinite* and *countable-uncountable*, a set is indeed at least as large as a subset. First we need a preliminary result.

If S is countably infinite and $A \subseteq S$ then A is countable.

Proof

It suffices to show that if A is an infinite subset of S then A is countably infinite. Since S is countably infinite, it can be enumerated: $S = \{x_0, x_1, x_2, \dots\}$. Let n_i be the i th smallest index such that $x_{n_i} \in A$. Then $A = \{x_{n_0}, x_{n_1}, x_{n_2}, \dots\}$ and hence is countably infinite.

Suppose that $A \subseteq B$.

1. If B is finite then A is finite.
2. If A is infinite then B is infinite.
3. If B is countable then A is countable.
4. If A is uncountable then B is uncountable.

Proof

1. This is clear from the definition of a finite set.
2. This is the contrapositive of (a).
3. If A is finite, then A is countable. If A is infinite, then B is infinite by (b) and hence is countably infinite. But then A is countably infinite by (9).
4. This is the contrapositive of (c).

Comparisons by one-to-one and onto functions

We will look deeper at the general question of when one set is “at least as big” as another, in the sense of cardinality. Not surprisingly, this will eventually lead to a partial order on the cardinality equivalence classes.

First note that if there exists a function that maps a set A one-to-one into a set B , then in a sense, there is a copy of A contained in B . Hence B should be at least as large as A .

Suppose that $f : A \rightarrow B$ is one-to-one.

1. If B is finite then A is finite.
2. If A is infinite then B is infinite.
3. If B is countable then A is countable.
4. If A is uncountable then B is uncountable.

Proof

Note that f maps A one-to-one onto $f(A)$. Hence $A \approx f(A)$ and $f(A) \subseteq B$. The results now follow from (10):

1. If B is finite then $f(A)$ is finite and hence A is finite.
2. If A is infinite then $f(A)$ is infinite and hence B is infinite.
3. If B is countable then $f(A)$ is countable and hence A is countable.
4. If A is uncountable then $f(A)$ is uncountable and hence B is uncountable.

On the other hand, if there exists a function that maps a set A onto a set B , then in a sense, there is a copy of B contained in A . Hence A should be at least as large as B .

Suppose that $f : A \rightarrow B$ is onto.

1. If A is finite then B is finite.
2. If B is infinite then A is infinite.
3. If A is countable then B is countable.
4. If B is uncountable then A is uncountable.

Proof

For each $y \in B$, select a specific $x \in A$ with $f(x) = y$ (if you are persnickety, you may need to invoke the axiom of choice). Let C be the set of chosen points. Then f maps C one-to-one onto B , so $C \approx B$ and $C \subseteq A$. The results now follow from (11):

1. If A is finite then C is finite and hence B is finite.
2. If B is infinite then C is infinite and hence A is infinite.
3. If A is countable then C is countable and hence B is countable.
4. If B is uncountable then C is uncountable and hence A is uncountable.

The previous exercise also could be proved from the one before, since if there exists a function f mapping A onto B , then there exists a function g mapping B one-to-one into A . This duality is proven in the discussion of the axiom of choice. A simple and useful corollary of the previous two theorems is that if B is a given countably infinite set, then a set A is countable if and only if there exists a one-to-one function f from A into B , if and only if there exists a function g from B onto A .

If A_i is a countable set for each i in a countable index set I , then $\bigcup_{i \in I} A_i$ is countable.

Proof

Consider the most extreme case in which the index set I is countably infinite. Since A_i is countable, there exists a function f_i that maps \mathbb{N} onto A_i for each $i \in \mathbb{N}$. Let $M = \{2^i 3^j : (i, j) \in \mathbb{N} \times \mathbb{N}\}$. Note that the points in M are distinct, that is, $2^i 3^j \neq 2^m 3^n$ if $(i, j), (m, n) \in \mathbb{N} \times \mathbb{N}$ and $(i, j) \neq (m, n)$. Hence M is infinite, and since $M \subset \mathbb{N}$, M is countably infinite. The function f given by $f(2^i 3^j) = f_i(j)$ for $(i, j) \in \mathbb{N} \times \mathbb{N}$ maps M onto $\bigcup_{i \in I} A_i$, and hence this last set is countable.

If A and B are countable then $A \times B$ is countable.

Proof

There exists a function f that maps \mathbb{N} onto A , and there exists a function g that maps \mathbb{N} onto B . Again, let $M = \{2^i 3^j : (i, j) \in \mathbb{N} \times \mathbb{N}\}$ and recall that M is countably infinite. Define $h : M \rightarrow A \times B$ by $h(2^i 3^j) = (f(i), g(j))$. Then h maps M onto $A \times B$ and hence this last set is countable.

The last result could also be proven from the one before, by noting that

$$A \times B = \bigcup_{a \in A} \{a\} \times B \quad (1.6.1)$$

Both proofs work because the set M is essentially a copy of $\mathbb{N} \times \mathbb{N}$, embedded inside of \mathbb{N} . The last theorem generalizes to the statement that a finite product of countable sets is still countable. But, from (5), a product of *infinitely* many sets (with at least 2 elements each) will be uncountable.

The set of rational numbers \mathbb{Q} is countably infinite.

Proof

The sets \mathbb{Z} and \mathbb{N}_+ are countably infinite and hence the set $\mathbb{Z} \times \mathbb{N}_+$ is countably infinite. The function $f : \mathbb{Z} \times \mathbb{N}_+ \rightarrow \mathbb{Q}$ given by $f(m, n) = \frac{m}{n}$ is onto.

A real number is *algebraic* if it is the root of a polynomial function (of degree 1 or more) with integer coefficients. Rational numbers are algebraic, as are rational roots of rational numbers (when defined). Moreover, the algebraic numbers are closed under addition, multiplication, and division. A real number is *transcendental* if it's not algebraic. The numbers e and π are transcendental, but we don't know very many other transcendental numbers by name. However, as we will see, most (in the sense of cardinality) real numbers are transcendental.

The set of algebraic numbers \mathbb{A} is countably infinite.

Proof

Let $\mathbb{Z}_0 = \mathbb{Z} \setminus \{0\}$ and let $\mathbb{Z}_n = \mathbb{Z}^{n-1} \times \mathbb{Z}_0$ for $n \in \mathbb{N}_+$. The set \mathbb{Z}_n is countably infinite for each n . Let $C = \bigcup_{n=1}^{\infty} \mathbb{Z}_n$. Think of C as the set of coefficients and note that C is countably infinite. Let P denote the set of polynomials of degree 1 or more, with integer coefficients. The function $(a_0, a_1, \dots, a_n) \mapsto a_0 + a_1 x + \dots + a_n x^n$ maps C onto P , and hence P is countable. For $p \in P$, let A_p denote the set of roots of p . A polynomial of degree n in P has at most n roots, by the *fundamental theorem of algebra*, so in particular A_p is finite for each $p \in P$. Finally, note that $\mathbb{A} = \bigcup_{p \in P} A_p$ and so \mathbb{A} is countable. Of course $\mathbb{N} \subset \mathbb{A}$, so \mathbb{A} is countably infinite.

Now let's look at some uncountable sets.

The interval $[0, 1)$ is uncountable.

Proof

Recall that $\{0, 1\}^{\mathbb{N}_+}$ is the set of all functions from \mathbb{N}_+ into $\{0, 1\}$, which in this case, can be thought of as infinite sequences or *bit strings*:

$$\{0, 1\}^{\mathbb{N}_+} = \{\mathbf{x} = (x_1, x_2, \dots) : x_n \in \{0, 1\} \text{ for all } n \in \mathbb{N}_+\} \quad (1.6.2)$$

By (5), this set is uncountable. Let $N = \{\mathbf{x} \in \{0, 1\}^{\mathbb{N}_+} : x_n = 1 \text{ for all but finitely many } n\}$, the set of bit strings that eventually terminate in all 1s. Note that $N = \bigcup_{n=1}^{\infty} N_n$ where $N_n = \{\mathbf{x} \in \{0, 1\}^{\mathbb{N}_+} : x_k = 1 \text{ for all } k \geq n\}$. Clearly N_n is finite for all $n \in \mathbb{N}_+$, so N is countable, and therefore $S = \{0, 1\}^{\mathbb{N}_+} \setminus N$ is uncountable. In fact, $S \approx \{0, 1\}^{\mathbb{N}_+}$. The function

$$\mathbf{x} \mapsto \sum_{n=1}^{\infty} \frac{x_n}{2^n} \quad (1.6.3)$$

maps S one-to-one onto $[0, 1)$. In words every number in $[0, 1)$ has a unique *binary expansion* in the form of a sequence in S . Hence $[0, 1) \approx S$ and in particular, is uncountable. The reason for eliminating the bit strings that terminate in 1s is to ensure uniqueness, so that the mapping is one-to-one. The bit string $x_1 x_2 \cdots x_k 0111 \cdots$ corresponds to the same number in $[0, 1)$ as the bit string $x_1 x_2 \cdots x_k 1000 \cdots$.

The following sets have the same cardinality, and in particular all are uncountable:

1. \mathbb{R} , the set of real numbers.
2. Any interval I of \mathbb{R} , as long as the interval is not empty or a single point.
3. $\mathbb{R} \setminus \mathbb{Q}$, the set of irrational numbers.
4. $\mathbb{R} \setminus \mathbb{A}$, the set of transcendental numbers.
5. $\mathcal{P}(\mathbb{N})$, the power set of \mathbb{N} .

Proof

1. The mapping $x \mapsto \frac{2x-1}{x(1-x)}$ maps $(0, 1)$ one-to-one onto \mathbb{R} so $(0, 1) \approx \mathbb{R}$. But $(0, 1) = [0, 1) \setminus \{0\}$, so $(0, 1) \approx (0, 1) \approx \mathbb{R}$, and all of these sets are uncountable by the previous result.
2. Suppose $a, b \in \mathbb{R}$ and $a < b$. The mapping $x \mapsto a + (b-a)x$ maps $(0, 1)$ one-to-one onto (a, b) and hence $(a, b) \approx (0, 1) \approx \mathbb{R}$. Also, $[a, b) = (a, b) \cup \{a\}$, $(a, b] = (a, b) \cup \{b\}$, and $[a, b] = (a, b) \cup \{a, b\}$, so $(a, b) \approx [a, b) \approx (a, b] \approx [a, b] \approx \mathbb{R}$. The function $x \mapsto e^x$ maps \mathbb{R} one-to-one onto $(0, \infty)$, so $(0, \infty) \approx \mathbb{R}$. For $a \in \mathbb{R}$, the function $x \mapsto a + x$ maps $(0, \infty)$ one-to-one onto (a, ∞) and the mapping $x \mapsto a - x$ maps $(0, \infty)$ one to one onto $(-\infty, a)$ so $(a, \infty) \approx (-\infty, a) \approx (0, \infty) \approx \mathbb{R}$. Next, $[a, \infty) = (a, \infty) \cup \{a\}$ and $(-\infty, a] = (-\infty, a) \cup \{a\}$, so $[a, \infty) \approx (-\infty, a] \approx \mathbb{R}$.
3. \mathbb{Q} is countably infinite, so $\mathbb{R} \setminus \mathbb{Q} \approx \mathbb{R}$.
4. Similarly, \mathbb{A} is countably infinite, so $\mathbb{R} \setminus \mathbb{A} \approx \mathbb{R}$.
5. If S is countably infinite, then by the previous result and (a), $\mathcal{P}(S) \approx \mathcal{P}(\mathbb{N}_+) \approx \{0, 1\}^{\mathbb{N}_+} \approx [0, 1)$.

The Cardinality Partial Order

Suppose that \mathcal{S} is a nonempty collection of sets. We define the relation \preceq on \mathcal{S} by $A \preceq B$ if and only if there exists a one-to-one function f from A into B , if and only if there exists a function g from B onto A . In light of the previous subsection, $A \preceq B$ should capture the notion that B is at least as big as A , in the sense of cardinality.

The relation \preceq is reflexive and transitive.

Proof

For $A \in \mathcal{S}$, the identity function $I_A : A \rightarrow A$ given by $I_A(x) = x$ is one-to-one (and also onto), so $A \preceq A$. Suppose that $A, B, C \in \mathcal{S}$ and that $A \preceq B$ and $B \preceq C$. Then there exist one-to-one functions $f : A \rightarrow B$ and $g : B \rightarrow C$. But then $g \circ f : A \rightarrow C$ is one-to-one, so $A \preceq C$.

Thus, we can use the construction in the section on [Equivalence Relations](#) to first define an equivalence relation on \mathcal{S} , and then extend \preceq to a true partial order on the collection of equivalence classes. The only question that remains is whether the equivalence relation we obtain in this way is the same as the one that we have been using in our study of cardinality. Rephrased, the question is this: *If there exists a one-to-one function from A into B and a one-to-one function from B into A , does there necessarily exist a one-to-one function from A onto B ?* Fortunately, the answer is yes; the result is known as the *Schröder-Bernstein Theorem*, named for Ernst Schröder and Felix Bernstein.

If $A \preceq B$ and $B \preceq A$ then $A \approx B$.

Proof

Set inclusion \subseteq is a partial order on $\mathcal{P}(A)$ (the power set of A) with the property that every subcollection of $\mathcal{P}(A)$ has a supremum (namely the union of the subcollection). Suppose that f maps A one-to-one into B and g maps B one-to-one into A . Define the function $h : \mathcal{P}(A) \rightarrow \mathcal{P}(A)$ by $h(U) = A \setminus g[B \setminus f(U)]$ for $U \subseteq A$. Then h is increasing:

$$U \subseteq V \implies f(U) \subseteq f(V) \implies B \setminus f(V) \subseteq B \setminus f(U) \quad (1.6.4)$$

$$\implies g[B \setminus f(V)] \subseteq g[B \setminus f(U)] \implies A \setminus g[B \setminus f(U)] \subseteq A \setminus g[B \setminus f(V)] \quad (1.6.5)$$

From the fixed point theorem for partially ordered sets, there exists $U \subseteq A$ such that $h(U) = U$. Hence $U = A \setminus g[B \setminus f(U)]$ and therefore $A \setminus U = g[B \setminus f(U)]$. Now define $F : A \rightarrow B$ by $F(x) = f(x)$ if $x \in U$ and $F(x) = g^{-1}(x)$ if $x \in A \setminus U$.

f maps U one-to-one onto $f(U)$; g maps $B \setminus f(U)$ one-to-one onto $A \setminus U$

 Schröder-Bernstein Theorem

Next we show that F is one-to-one. Suppose that $x_1, x_2 \in A$ and $F(x_1) = F(x_2)$. If $x_1, x_2 \in U$ then $f(x_1) = f(x_2)$ so $x_1 = x_2$ since f is one-to-one. If $x_1, x_2 \in A \setminus U$ then $g^{-1}(x_1) = g^{-1}(x_2)$ so $x_1 = x_2$ since g^{-1} is one-to-one. If $x_1 \in U$ and $x_2 \in A \setminus U$. Then $F(x_1) = f(x_1) \in f(U)$ while $F(x_2) = g^{-1}(x_2) \in B \setminus f(U)$, so $F(x_1) = F(x_2)$ is impossible.

Finally we show that F is onto. Let $y \in B$. If $y \in f(U)$ then $y = f(x)$ for some $x \in U$ so $F(x) = y$. If $y \in B \setminus f(U)$ then $x = g(y) \in A \setminus U$ so $F(x) = g^{-1}(x) = y$.

We will write $A \prec B$ if $A \preceq B$, but $A \not\approx B$. That is, there exists a one-to-one function from A into B , but there does not exist a function from A onto B . Note that \prec would have its usual meaning if applied to the equivalence classes. That is, $[A] \prec [B]$ if and only if $[A] \preceq [B]$ but $[A] \neq [B]$. Intuitively, of course, $A \prec B$ means that B is strictly larger than A , in the sense of cardinality.

$A \prec B$ in each of the following cases:

1. A and B are finite and $\#(A) < \#(B)$.
2. A is finite and B is countably infinite.
3. A is countably infinite and B is uncountable.

We close our discussion with the observation that for any set, there is always a larger set.

If S is a set then $S \prec \mathcal{P}(S)$.

Proof

First, it's trivial to map S one-to-one into $\mathcal{P}(S)$; just map x to $\{x\}$. Suppose now that f maps S onto $\mathcal{P}(S)$ and let $R = \{x \in S : x \notin f(x)\}$. Since f is onto, there exists $t \in S$ such that $f(t) = R$. Note that $t \in f(t)$ if and only if $t \notin f(t)$.

The proof that a set cannot be mapped onto its power set is similar to the *Russell paradox*, named for Bertrand Russell.

The *continuum hypothesis* is the statement that there is no set whose cardinality is strictly between that of \mathbb{N} and \mathbb{R} . The continuum hypothesis actually started out as the *continuum conjecture*, until it was shown to be consistent with the usual axioms of the real number system (by Kurt Gödel in 1940), and independent of those axioms (by Paul Cohen in 1963).

Assuming the continuum hypothesis, if S is uncountable then there exists $A \subseteq S$ such that A and A^c are uncountable.

Proof

Under the continuum hypothesis, if S is uncountable then $[0, 1] \preceq S$. Hence there exists a one-to-one function $f : [0, 1] \rightarrow S$. Let $A = f\left[0, \frac{1}{2}\right)$. Then A is uncountable, and since $f\left[\frac{1}{2}, 1\right) \subseteq A^c$, A^c is uncountable.

There is a more complicated proof of the last result, without the continuum hypothesis and just using the axiom of choice.

This page titled [1.6: Cardinality](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

1.7: Counting Measure

Basic Theory

For our first discussion, we assume that the universal set S is finite. Recall the following definition from the section on [cardinality](#).

For $A \subseteq S$, the *cardinality* of A is the number of elements in A , and is denoted $\#(A)$. The function $\#$ on $\mathcal{P}(S)$ is called *counting measure*.

Counting measure plays a fundamental role in discrete probability structures, and particularly those that involve sampling from a finite set. The set S is typically very large, hence efficient counting methods are essential. The first combinatorial problem is attributed to the Greek mathematician Xenocrates.

In many cases, a set of objects can be counted by establishing a one-to-one correspondence between the given set and some other set. Naturally, the two sets have the same number of elements, but for various reasons, the second set may be easier to count.

The Addition Rule

The *addition rule* of combinatorics is simply the additivity axiom of counting measure.

If $\{A_1, A_2, \dots, A_n\}$ is a collection of disjoint subsets of S then

$$\# \left(\bigcup_{i=1}^n A_i \right) = \sum_{i=1}^n \#(A_i) \quad (1.7.1)$$

Figure 1.7.1: The addition rule

The following counting rules are simple consequences of the [addition rule](#). Be sure to try the proofs yourself before reading the ones in the text.

$\#(A^c) = \#(S) - \#(A)$. This is the *complement rule*.

Proof

Figure 1.7.2: The complement rule

$\#(B \setminus A) = \#(B) - \#(A \cap B)$. This is the *difference rule*.

Proof

Note that $A \cap B$ and $B \setminus A$ are disjoint and their union is B . Hence $\#(A \cap B) + \#(B \setminus A) = \#(B)$.

If $A \subseteq B$ then $\#(B \setminus A) = \#(B) - \#(A)$. This is the *proper difference rule*.

Proof

This follows from the difference rule, since $A \cap B = A$.

If $A \subseteq B$ then $\#(A) \leq \#(B)$.

Proof

This follows from the proper difference rule: $\#(B) = \#(A) + \#(B \setminus A) \geq \#(A)$.

Thus, $\#$ is an increasing function, relative to the subset partial order \subseteq on $\mathcal{P}(S)$, and the ordinary order \leq on \mathbb{N} .

Inequalities

Our next discussion concerns two inequalities that are useful for obtaining bounds on the number of elements in a set. The first is *Boole's inequality* (named after George Boole) which gives an upper bound on the cardinality of a union.

If $\{A_1, A_2, \dots, A_n\}$ is a finite collection of subsets of S then

$$\# \left(\bigcup_{i=1}^n A_i \right) \leq \sum_{i=1}^n \#(A_i) \quad (1.7.2)$$

Proof

Let $B_1 = A_1$ and $B_i = A_i \setminus (A_1 \cup \dots \cup A_{i-1})$ for $i \in \{2, 3, \dots, n\}$. Note that $\{B_1, B_2, \dots, B_n\}$ is a pairwise disjoint collection and has the same union as $\{A_1, A_2, \dots, A_n\}$. From the [increasing property](#), $\#(B_i) \leq \#(A_i)$ for each $i \in \{1, 2, \dots, n\}$. Hence by the [addition rule](#),

$$\# \left(\bigcup_{i=1}^n A_i \right) = \# \left(\bigcup_{i=1}^n B_i \right) \leq \sum_{i=1}^n \#(A_i) \quad (1.7.3)$$

Intuitively, Boole's inequality holds because parts of the union have been counted more than once in the expression on the right. The second inequality is *Bonferroni's inequality* (named after Carlo Bonferroni), which gives a lower bound on the cardinality of an intersection.

If $\{A_1, A_2, \dots, A_n\}$ is a finite collection of subsets of S then

$$\# \left(\bigcap_{i=1}^n A_i \right) \geq \#(S) - \sum_{i=1}^n [\#(S) - \#(A_i)] \quad (1.7.4)$$

Proof

Using the [complement rule](#), [Boole's inequality](#), and DeMorgan's law,

$$\# \left(\bigcap_{i=1}^n A_i \right) = \#(S) - \# \left(\bigcup_{i=1}^n A_i^c \right) \geq \#(S) - \sum_{i=1}^n \#(A_i^c) = \#(S) - \sum_{i=1}^n [\#(S) - \#(A_i)] \quad (1.7.5)$$

The Inclusion-Exclusion Formula

The inclusion-exclusion formula gives the cardinality of a union of sets in terms of the cardinality of the various intersections of the sets. The formula is useful because intersections are often easier to count. We start with the special cases of two sets and three sets. As usual, we assume that the sets are subsets of a finite universal set S .

If A and B are subsets of S then $\#(A \cup B) = \#(A) + \#(B) - \#(A \cap B)$.

Proof

Figure 1.7.3: The inclusion-exclusion theorem for two sets

If A, B, C are subsets of S then $\#(A \cup B \cup C) = \#(A) + \#(B) + \#(C) - \#(A \cap B) - \#(A \cap C) - \#(B \cap C) + \#(A \cap B \cap C)$.

Figure 1.7.4: The inclusion-exclusion theorem for three sets

The inclusion-exclusion rule for two and three sets can be generalized to a union of n sets; the generalization is known as the (general) *inclusion-exclusion formula*.

Suppose that $\{A_i : i \in I\}$ is a collection of subsets of S where I is an index set with $\#(I) = n$. Then

$$\# \left(\bigcup_{i \in I} A_i \right) = \sum_{k=1}^n (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \# \left(\bigcap_{j \in J} A_j \right) \quad (1.7.6)$$

Proof

The proof is by induction on n . The formula holds for $n = 2$ sets by the result for [two sets](#). Suppose the formula holds for $n \in \{2, 3, \dots\}$, and suppose that $\{A_1, A_2, \dots, A_n, A_{n+1}\}$ is a collection of $n + 1$ subsets of S . Then

$$\bigcup_{i=1}^{n+1} A_i = \left(\bigcup_{i=1}^n A_i \right) \cup \left[A_{n+1} \setminus \left(\bigcup_{i=1}^n A_i \right) \right] \quad (1.7.7)$$

and the two sets connected by the central union are disjoint. Using the [addition rule](#) and the [difference rule](#),

$$\# \left(\bigcup_{i=1}^{n+1} A_i \right) = \# \left(\bigcup_{i=1}^n A_i \right) + \#(A_{n+1}) - \# \left[A_{n+1} \cap \left(\bigcup_{i=1}^n A_i \right) \right] \quad (1.7.8)$$

$$= \# \left(\bigcup_{i=1}^n A_i \right) + \#(A_{n+1}) - \# \left[\bigcup_{i=1}^n (A_i \cap A_{n+1}) \right] \quad (1.7.9)$$

By the induction hypothesis, the formula holds for the two unions of n sets in the last expression. The result then follows by simplification.

The general *Bonferroni inequalities*, named again for Carlo Bonferroni, state that if sum on the right is truncated after k terms ($k < n$), then the truncated sum is an *upper* bound for the cardinality of the union if k is odd (so that the last term has a positive sign) and is a *lower* bound for the cardinality of the union if k is even (so that the last terms has a negative sign).

The Multiplication Rule

The *multiplication rule* of combinatorics is based on the formulation of a *procedure* (or *algorithm*) that generates the objects to be counted.

Suppose that a procedure consists of k steps, performed sequentially, and that for each $j \in \{1, 2, \dots, k\}$, step j can be performed in n_j ways, regardless of the choices made on the previous steps. Then the number of ways to perform the entire procedure is $n_1 n_2 \cdots n_k$.

The key to a successful application of the multiplication rule to a counting problem is the clear formulation of an algorithm that generates the objects being counted, so that each object is generated once and only once. That is, we must neither over count nor under count. It's also important to notice that the set of choices available at step j may well depend on the previous steps; the assumption is only that the *number* of choices available does not depend on the previous steps.

The first two results below give equivalent formulations of the multiplication principle.

Suppose that S is a set of sequences of length k , and that we denote a generic element of S by (x_1, x_2, \dots, x_k) . Suppose that for each $j \in \{1, 2, \dots, k\}$, x_j has n_j different values, regardless of the values of the previous coordinates. Then $\#(S) = n_1 n_2 \cdots n_k$.

Proof

A procedure that generates the sequences in S consists of k steps. Step j is to select the j th coordinate.

Suppose that T is an ordered tree with depth k and that each vertex at level $i - 1$ has n_i children for $i \in \{1, 2, \dots, k\}$. Then the number of endpoints of the tree is $n_1 n_2 \cdots n_k$.

Proof

Each endpoint of the tree is uniquely associated with the path from the root vertex to the endpoint. Each such path is a sequence of length k , in which there are n_j values for coordinate j for each $j \in \{1, 2, \dots, k\}$. Hence the result follows from the result above on sequences.

Product Sets

If S_i is a set with n_i elements for $i \in \{1, 2, \dots, k\}$ then

$$\#(S_1 \times S_2 \times \cdots \times S_k) = n_1 n_2 \cdots n_k \quad (1.7.10)$$

Proof

This is a corollary of the result above on sequences.

If S is a set with n elements, then S^k has n^k elements.

Proof

This is a corollary of the previous result.

In (16), note that the elements of S^k can be thought of as ordered samples of size k that can be chosen with replacement from a population of n objects. Elements of $\{0, 1\}^n$ are sometimes called *bit strings* of length n . Thus, there are 2^n bit strings of length n .

Functions

The number of functions from a set A of m elements into a set B of n elements is n^m .

Proof

An algorithm for constructing a function $f : A \rightarrow B$ is to choose the value of $f(x) \in B$ for each $x \in A$. There are n choices for each of the m elements in the domain.

Recall that the set of functions from a set A into a set B (regardless of whether the sets are finite or infinite) is denoted B^A . This theorem is motivation for the notation. Note also that if S is a set with n elements, then the elements in the Cartesian power set S^k can be thought of as functions from $\{1, 2, \dots, k\}$ into S . So the counting formula for sequences can be thought of as a corollary of counting formula for functions.

Subsets

Suppose that S is a set with n elements, where $n \in \mathbb{N}$. There are 2^n subsets of S .

Proof from the multiplication principle

An algorithm for constructing $A \subseteq S$, is to decide whether $x \in A$ or $x \notin A$ for each $x \in S$. There are 2 choices for each of the n elements of S .

Proof using indicator functions

Recall that there is a one-to-one correspondence between subsets of S and indicator functions on S . An indicator function is simply a function from S into $\{0, 1\}$, and the number of such functions is 2^n by the previous result.

Suppose that $\{A_1, A_2, \dots, A_k\}$ is a collection of k subsets of a set S , where $k \in \mathbb{N}_+$. There are 2^{2^k} different (in general) sets that can be constructed from the k given sets, using the operations of union, intersection, and complement. These sets form the algebra generated by the given sets.

Proof

First note that there are 2^k pairwise disjoint sets of the form $B_1 \cap B_2 \cap \cdots \cap B_k$ where $B_i = A_i$ or $B_i = A_i^c$ for each i . Next, note that every set that can be constructed from $\{A_1, A_2, \dots, A_n\}$ is a union of some (perhaps all, perhaps none) of these intersection sets.

Open the Venn diagram app.

1. Select each of the 4 disjoint sets $A \cap B$, $A \cap B^c$, $A^c \cap B$, $A^c \cap B^c$.
2. Select each of the 12 other subsets of S . Note how each is a union of some of the sets in (a).

Suppose that S is a set with n elements and that A is a subset of S with k elements, where $n, k \in \mathbb{N}$ and $k \leq n$. The number of subsets of S that contain A is 2^{n-k} .

Proof

Note that subset B of S that contains A can be written uniquely in the form $B = A \cup C$ where $C \subseteq A^c$. A^c has $n - k$ elements and hence there are 2^{n-k} subsets of A^c by the general [subset result](#).

Our last result in this discussion generalizes the basic [subset result](#) above.

Suppose that $n, k \in \mathbb{N}$ and that S is a set with n elements. The number of sequences of subsets (A_1, A_2, \dots, A_k) with $A_1 \subseteq A_2 \subseteq \cdots \subseteq A_k \subseteq S$ is $(k+1)^n$.

Proof

To construct a sequence of the type in the theorem, we can use the following algorithm: For each $x \in S$, either x is not in the sets, or x occurs for the first time in set A_i where $i \in \{1, 2, \dots, k\}$. (That is, $x \notin A_j$ for $j \in \{1, \dots, i-1\}$ and $x \in A_i$ for $j \in \{i, \dots, k\}$.) So there are $k+1$ choices for each of the n elements of S .

When $k = 1$ we get 2^n as the number of subsets of S , as before.

Computational Exercises

Identification Numbers

A license number consists of two letters (uppercase) followed by five digits. How many different license numbers are there?

Answer

$$26^2 \cdot 10^5 = 67\,600\,000$$

Suppose that a Personal Identification Number (PIN) is a four-symbol code word in which each entry is either a letter (uppercase) or a digit. How many PINs are there?

Answer

$$36^4 = 1\,679\,616$$

Cards, Dice, and Coins

In the board game [Clue](#), Mr. Boddy has been murdered. There are 6 suspects, 6 possible weapons, and 9 possible rooms for the murder.

1. The game includes a card for each suspect, each weapon, and each room. How many cards are there?
2. The outcome of the game is a sequence consisting of a suspect, a weapon, and a room (for example, *Colonel Mustard with the knife in the billiard room*). How many outcomes are there?
3. Once the three cards that constitute the outcome have been randomly chosen, the remaining cards are dealt to the players. Suppose that you are dealt 5 cards. In trying to guess the outcome, what hand of cards would be best?

Answer

1. $6 + 6 + 9 = 21$ cards

2. $6 \cdot 6 \cdot 9 = 324$ outcomes

3. The best hand would be the 5 remaining weapons or the 5 remaining suspects.

An experiment consists of rolling a standard die, drawing a card from a standard deck, and tossing a standard coin. How many outcomes are there?

Answer

$$6 \cdot 52 \cdot 2 = 624$$

A standard die is rolled 5 times and the sequence of scores recorded. How many outcomes are there?

Answer

$$6^5 = 7776$$

In the card game *Set*, each card has 4 properties: *number* (one, two, or three), *shape* (diamond, oval, or squiggle), *color* (red, blue, or green), and *shading* (solid, open, or stripped). The deck has one card of each (number, shape, color, shading) configuration. A *set* in the game is defined as a set of three cards which, for each property, the cards are either all the same or all different.

1. How many cards are in a deck?

2. How many sets are there?

Answer

1. $3^4 = 81$

2. 1080

A coin is tossed 10 times and the sequence of scores recorded. How many sequences are there?

Answer

$$2^{10} = 1024$$

The die-coin experiment consists of rolling a die and then tossing a coin the number of times shown on the die. The sequence of coin results is recorded.

1. How many outcomes are there?

2. How many outcomes are there with all heads?

3. How many outcomes are there with exactly one head?

Answer

1. $\sum_{k=1}^6 2^k = 126$

2. 6

3. $\sum_{k=1}^6 k = 21$

Run the die-coin experiment 100 times and observe the outcomes.

Consider a deck of cards as a set D with 52 elements.

1. How many subsets of D are there?

2. How many functions are there from D into the set $\{1, 2, 3, 4\}$?

Answer

1. $2^{52} = 4\,503\,599\,627\,370\,496$

2. $4^{52} = 20\,282\,409\,603\,651\,670\,423\,947\,251\,286\,016$

Birthdays

Consider a group of 10 persons.

1. If we record the birth month of each person, how many outcomes are there?
2. If we record the birthday of each person (ignoring leap day), how many outcomes are there?

Answer

1. $12^{10} = 61\,917\,364\,224$
2. $365^{10} = 41\,969\,002\,243\,198\,805\,166\,015\,625$

Reliability

In the usual model of *structural reliability*, a system consists of *components*, each of which is either *working* or *defective*. The system as a whole is also either working or defective, depending on the states of the components and how the components are connected.

A string of lights has 20 bulbs, each of which may be good or defective. How many configurations are there?

Answer

$$2^{20} = 1\,048\,576$$

If the components are connected in *series*, then the system as a whole is working if and only if each component is working. If the components are connected *parallel*, then the system as a whole is working if and only if at least one component is working.

A system consists of three subsystems with 6, 5, and 4 components, respectively. Find the number of component states for which the system is working in each of the following cases:

1. The components in each subsystem are in parallel and the subsystems are in series.
2. The components in each subsystem are in series and the subsystems are in parallel.

Answer

1. $(2^6 - 1)(2^5 - 1)(2^4 - 1) = 29\,295$
2. $2^3 - 1 = 7$

Menus

Suppose that a sandwich at a restaurant consists of bread, meat, cheese, and various toppings. There are 4 choices for the bread, 3 choices for the meat, 5 choices for the cheese, and 10 different toppings (each of which may be chosen). How many sandwiches are there?

Answer

$$4 \cdot 3 \cdot 5 \cdot 2^{10} = 61\,440$$

At a wedding dinner, there are three choices for the entrée, four choices for the beverage, and two choices for the dessert.

1. How many different meals are there?
2. If there are 50 guests at the wedding and we record the meal requested for each guest, how many possible outcomes are there?

Answer

1. $3 \cdot 4 \cdot 2 = 24$
2. $24^{50} \approx 1.02462 \times 10^{69}$

Braille

Braille is a tactile writing system used by people who are visually impaired. The system is named for the French educator Louis Braille and uses raised dots in a 3×2 grid to encode characters. How many meaningful Braille configurations are there?

Answer

Figure 1.7.5: The Braille encoding of the number 2 and the letter *b*

Personality Typing

The *Meyers-Briggs* personality typing is based on four dichotomies: A person is typed as either *extroversion* (E) or *introversion* (I), either *sensing* (S) or *intuition* (I), either *thinking* (T) or *feeling* (F), and either *judgement* (J) or *perception* (P).

1. How many Meyers-Briggs personality types are there? List them.
2. Suppose that we list the personality types of 10 persons. How many possible outcomes are there?

Answer

1. 16
2. $16^{10} = 1\,099\,511\,627\,776$

The Galton Board

The *Galton Board*, named after Francis Galton, is a triangular array of pegs. Galton, apparently too modest to name the device after himself, called it a *quincunx* from the Latin word for five twelfths (go figure). The rows are numbered, from the top down, by $(0, 1, \dots)$. Row n has $n + 1$ pegs that are labeled, from left to right by $(0, 1, \dots, n)$. Thus, a peg can be uniquely identified by an ordered pair (n, k) where n is the row number and k is the peg number in that row.

A ball is dropped onto the top peg $(0, 0)$ of the Galton board. In general, when the ball hits peg (n, k) , it either bounces to the left to peg $(n + 1, k)$ or to the right to peg $(n + 1, k + 1)$. The sequence of pegs that the ball hits is a *path* in the Galton board.

There is a one-to-one correspondence between each pair of the following three collections:

1. Bit strings of length n
2. Paths in the Galton board from $(0, 0)$ to any peg in row n .
3. Subsets of a set with n elements.

Thus, each of these collections has 2^n elements.

Open the Galton board app.

1. Move the ball from $(0, 0)$ to $(10, 6)$ along a path of your choice. Note the corresponding bit string and subset.
2. Generate the bit string 0111001010 Note the corresponding subset and path.
3. Generate the subset $\{2, 4, 5, 9, 10\}$ Note the corresponding bit string and path.
4. Generate all paths from $(0, 0)$ to $(4, 2)$. How many paths are there?

Answer

4. 6

This page titled [1.7: Counting Measure](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

1.8: Combinatorial Structures

The purpose of this section is to study several combinatorial structures that are of basic importance in probability.

Permutations

Suppose that D is a set with $n \in \mathbb{N}$ elements. A *permutation* of length $k \in \{0, 1, \dots, n\}$ from D is an ordered sequence of k distinct elements of D ; that is, a sequence of the form (x_1, x_2, \dots, x_k) where $x_i \in D$ for each i and $x_i \neq x_j$ for $i \neq j$.

Statistically, a permutation of length k from D corresponds to an *ordered sample* of size k chosen *without replacement* from the population D .

The number of permutations of length k from an n element set is

$$n^{(k)} = n(n-1) \cdots (n-k+1) \quad (1.8.1)$$

Proof

This follows easily from the multiplication principle. There are n ways to choose the first element, $n-1$ ways to choose the second element, and so forth.

By convention, $n^{(0)} = 1$. Recall that, in general, a product over an empty index set is 1. Note that $n^{(k)}$ has k factors, starting at n , and with each subsequent factor one less than the previous factor. Some alternate notations for the number of permutations of size k from a set of n objects are $P(n, k)$, $P_{n,k}$, and ${}_nP_k$.

The number of permutations of length n from the n element set D (these are called simply *permutations* of D) is

$$n! = n^{(n)} = n(n-1) \cdots (1) \quad (1.8.2)$$

The function on \mathbb{N} given by $n \mapsto n!$ is the *factorial function*. The general permutation formula in (2) can be written in terms of factorials:

For $n \in \mathbb{N}$ and $k \in \{0, 1, \dots, n\}$

$$n^{(k)} = \frac{n!}{(n-k)!} \quad (1.8.3)$$

Although this formula is succinct, it's not always a good idea numerically. If n and $n-k$ are large, $n!$ and $(n-k)!$ are enormous, and division of the first by the second can lead to significant round-off errors.

Note that the basic permutation formula in (2) is defined for every real number n and nonnegative integer k . This extension is sometimes referred to as the *generalized permutation formula*. Actually, we will sometimes need an even more general formula of this type (particularly in the sections on [Pólya's urn](#) and the [beta-Bernoulli process](#)).

For $a \in \mathbb{R}$, $s \in \mathbb{R}$, and $k \in \mathbb{N}$, define

$$a^{(s,k)} = a(a+s)(a+2s) \cdots [a+(k-1)s] \quad (1.8.4)$$

1. $a^{(0,k)} = a^k$
2. $a^{(-1,k)} = a^{(k)}$
3. $a^{(1,k)} = a(a+1) \cdots (a+k-1)$
4. $1^{(1,k)} = k!$

The product $a^{(-1,k)} = a^{(k)}$ (our ordinary permutation formula) is sometimes called the *falling power* of a of order k , while $a^{(1,k)}$ is called the *rising power* of a of order k , and is sometimes denoted $a^{[k]}$. Note that $a^{(0,k)}$ is the ordinary k th power of a . In general, note that $a^{(s,k)}$ has k factors, starting at a and with each subsequent factor obtained by adding s to the previous factor.

Combinations

Consider again a set D with $n \in \mathbb{N}$ elements. A *combination* of size $k \in \{0, 1, \dots, n\}$ from D is an (unordered) subset of k distinct elements of D . Thus, a combination of size k from D has the form $\{x_1, x_2, \dots, x_k\}$, where $x_i \in D$ for each i and $x_i \neq x_j$ for $i \neq j$.

Statistically, a combination of size k from D corresponds to an *unordered sample* of size k chosen *without replacement* from the population D . Note that for each combination of size k from D , there are $k!$ distinct orderings of the elements of that combination. Each of these is a permutation of length k from D . The number of combinations of size k from an n -element set is denoted by $\binom{n}{k}$. Some alternate notations are $C(n, k)$, $C_{n,k}$, and ${}_nC_k$.

The number of combinations of size k from an n element set is

$$\binom{n}{k} = \frac{n^{(k)}}{k!} = \frac{n!}{k!(n-k)!} \quad (1.8.5)$$

Proof

An algorithm for generating all permutations of size k from D is to first select a combination of size k and then to select an ordering of the elements. From the multiplication principle it follows that $n^{(k)} = \binom{n}{k}k!$. Hence $\binom{n}{k} = n^{(k)} / k! = n! / [k!(n-k)!]$.

The number $\binom{n}{k}$ is called a *binomial coefficient*. Note that the formula makes sense for any real number n and nonnegative integer k since this is true of the generalized permutation formula $n^{(k)}$. With this extension, $\binom{n}{k}$ is called the *generalized binomial coefficient*. Note that if n and k are positive integers and $k > n$ then $\binom{n}{k} = 0$. By convention, we will also define $\binom{n}{k} = 0$ if $k < 0$. This convention sometimes simplifies formulas.

Properties of Binomial Coefficients

For some of the identities below, there are two possible proofs. An algebraic proof, of course, should be based on (5). A *combinatorial proof* is constructed by showing that the left and right sides of the identity are two different ways of counting the same collection.

$$\binom{n}{n} = \binom{n}{0} = 1.$$

Algebraically, the last result is trivial. It also makes sense combinatorially: There is only one way to select a subset of D with n elements (D itself), and there is only one way to select a subset of size 0 from D (the empty set \emptyset).

If $n, k \in \mathbb{N}$ with $k \leq n$ then

$$\binom{n}{k} = \binom{n}{n-k} \quad (1.8.6)$$

Combinatorial Proof

Note that if we select a subset of size k from a set of size n , then we leave a subset of size $n - k$ behind (the complement). Thus $A \mapsto A^c$ is a one-to-one correspondence between subsets of size k and subsets of size $n - k$.

The next result is one of the most famous and most important. It's known as *Pascal's rule* and is named for Blaise Pascal.

If $n, k \in \mathbb{N}_+$ with $k \leq n$ then

$$\binom{n}{k} = \binom{n-1}{k-1} + \binom{n-1}{k} \quad (1.8.7)$$

Combinatorial Proof

Suppose that we have n persons, one named Fred, and that we want to select a committee of size k . There are $\binom{n}{k}$ different committees. On the other hand, there are $\binom{n-1}{k-1}$ committees with Fred as a member, and $\binom{n-1}{k}$ committees without Fred as a member. The sum of these two numbers is also the number of committees.

Recall that the *Galton board* is a triangular array of pegs: the rows are numbered $n = 0, 1, \dots$ and the pegs in row n are numbered $k = 0, 1, \dots, n$. If each peg in the Galton board is replaced by the corresponding binomial coefficient, the resulting table of numbers is known as *Pascal's triangle*, named again for Pascal. By (8), each interior number in Pascal's triangle is the sum of the two numbers directly above it.

The following result is the *binomial theorem*, and is the reason for the term *binomial coefficient*.

If $a, b \in \mathbb{R}$ and $n \in \mathbb{N}$ is a positive integer, then

$$(a + b)^n = \sum_{k=0}^n \binom{n}{k} a^k b^{n-k} \quad (1.8.8)$$

Combinatorial Proof

Note that to get the term $a^k b^{n-k}$ in the expansion of $(a + b)^n$, we must select a from k of the factors and b from the remaining $n - k$ factors. The number of ways to do this is $\binom{n}{k}$.

If $j, k, n \in \mathbb{N}_+$ with $j \leq k \leq n$ then

$$k^{(j)} \binom{n}{k} = n^{(j)} \binom{n-j}{k-j} \quad (1.8.9)$$

Combinatorial Proof

Consider two procedures for selecting a committee of size k from a group of n persons, with j distinct members of the committee as officers (chair, vice chair, etc.). For the first procedure, select the committee from the population and then select the member of the committee to be the officers. The number of ways to perform the first step is $\binom{n}{k}$ and the number of ways to perform the second step is $k^{(j)}$. So by the multiplication principle, the number of ways to choose the committee is the left side of the equation. For the second procedure, select the officers of the committee from the population and then select $k - j$ other committee members from the remaining $n - j$ members of the population. The number of ways to perform the first step is $n^{(j)}$ and the number of ways to perform the second step is $\binom{n-j}{k-j}$. So by the multiplication principle, the number of committees is the right side of the equation.

The following result is known as *Vandermonde's identity*, named for Alexandre-Théophile Vandermonde.

If $m, n, k \in \mathbb{N}$ with $k \leq m + n$, then

$$\sum_{j=0}^k \binom{m}{j} \binom{n}{k-j} = \binom{m+n}{k} \quad (1.8.10)$$

Combinatorial Proof

Suppose that a committee of size k is chosen from a group of $m + n$ persons, consisting of m men and n women. The number of committees with exactly j men and $k - j$ women is $\binom{m}{j} \binom{n}{k-j}$. The sum of this product over j is the total number of committees, which is $\binom{m+n}{k}$.

The next result is a general identity for the sum of binomial coefficients.

If $m, n \in \mathbb{N}$ with $n \leq m$ then

$$\sum_{j=n}^m \binom{j}{n} = \binom{m+1}{n+1} \quad (1.8.11)$$

Combinatorial Proof

Suppose that we pick a subset of size $n + 1$ from the set $\{1, 2, \dots, m + 1\}$. For $j \in \{n, n + 1, \dots, m\}$, the number of subsets in which the largest element is $j + 1$ is $\binom{j}{n}$. Hence the sum of these numbers over j is the total number of subsets of size $n + 1$, which is also $\binom{m+1}{n+1}$.

For an even more general version of the last result, see the section on [Order Statistics](#) in the chapter on Finite Sampling Models. The following identity for the sum of the first m positive integers is a special case of the last result.

If $m \in \mathbb{N}$ then

$$\sum_{j=1}^m j = \binom{m+1}{2} = \frac{(m+1)m}{2} \quad (1.8.12)$$

Proof

Let $n = 1$ in previous result.

There is a one-to-one correspondence between each pair of the following collections. Hence the number objects in each of these collection is $\binom{n}{k}$.

1. Subsets of size k from a set of n elements.
2. Bit strings of length n with exactly k 1's.
3. Paths in the Galton board from $(0, 0)$ to (n, k) .

Proof

Let $S = \{x_1, x_2, \dots, x_n\}$ be a set with n elements. A one-to-one correspondence between the subsets A of S with k elements and the bit strings $\mathbf{b} = b_1 b_2 \dots b_n$ of length n with k 1's can be constructed by the rule that $x_i \in A$ if and only if $b_i = 1$. In turn, a one-to-one correspondence between the bit strings \mathbf{b} in part (b) and the paths in Galton board in part (c) can be constructed by the rule that in row $i \in \{0, 1, \dots, n-1\}$, turn right if $b_{i+1} = 1$ and turn left if $b_{i+1} = 0$.

The following identity is known as the *alternating sum identity* for binomial coefficients. It turns out to be useful in the [Irwin-Hall probability distribution](#). We give the identity in two equivalent forms, one for falling powers and one for ordinary powers.

If $n \in \mathbb{N}_+$, $j \in \{0, 1, \dots, n-1\}$ then

$$1. \quad \sum_{k=0}^n \binom{n}{k} (-1)^k k^{(j)} = 0 \quad (1.8.13)$$

$$2. \quad \sum_{k=0}^n \binom{n}{k} (-1)^k k^j = 0 \quad (1.8.14)$$

Proof

1. We use the [identity](#) above and the binomial theorem [binomial theorem](#):

$$\begin{aligned} \sum_{k=0}^n (-1)^k k^{(j)} \binom{n}{k} &= \sum_{k=j}^n (-1)^k k^{(j)} \binom{n}{k} = \sum_{k=j}^n (-1)^k n^{(j)} \binom{n-j}{k-j} \\ &= n^{(j)} (-1)^j \sum_{k=j}^n (-1)^{k-j} \binom{n-j}{k-j} = n^{(j)} (-1)^j \sum_{i=0}^{n-j} (-1)^i \binom{n-j}{i} \\ &= n^{(j)} (-1)^j (-1+1)^{n-j} = 0. \end{aligned}$$

Note that it's the last step where we need $j < n$.

2. This follows from (a), since k^j is a linear combination of $k^{(i)}$ for $i \in \{0, 1, \dots, j\}$. That is, there exists $c_i \in \mathbb{R}$ for $i \in \{0, 1, \dots, j\}$ such that $k^j = \sum_{i=0}^j c_i k^{(i)}$. Hence

$$\sum_{k=0}^n (-1)^k k^j \binom{n}{k} = \sum_{i=0}^j c_i \sum_{k=0}^n (-1)^k k^{(i)} \binom{n}{k} = 0 \quad (1.8.15)$$

Our next identity deals with a generalized binomial coefficient.

If $n, k \in \mathbb{N}$ then

$$\binom{-n}{k} = (-1)^k \binom{n+k-1}{k} \quad (1.8.16)$$

Proof

Note that

$$\binom{-n}{k} = \frac{(-n)^{(k)}}{k!} = \frac{(-n)(-n-1)\cdots(-n-k+1)}{k!} \quad (1.8.17)$$

$$= (-1)^k \frac{(n+k-1)(n+k-2)\cdots(n)}{k!} = (-1)^k \frac{(n+k-1)^{(k)}}{k!} = (-1)^k \binom{n+k-1}{k} \quad (1.8.18)$$

In particular, note that $\binom{-1}{k} = (-1)^k$. Our last result in this discussion concerns the binomial operator and its inverse.

The *binomial operator* takes a sequence of real numbers $\mathbf{a} = (a_0, a_1, a_2, \dots)$ and returns the sequence of real numbers $\mathbf{b} = (b_0, b_1, b_2, \dots)$ by means of the formula

$$b_n = \sum_{k=0}^n \binom{n}{k} a_k, \quad n \in \mathbb{N} \quad (1.8.19)$$

The *inverse binomial operator* recovers the sequence \mathbf{a} from the sequence \mathbf{b} by means of the formula

$$a_n = \sum_{k=0}^n (-1)^{n-k} \binom{n}{k} b_k, \quad n \in \mathbb{N} \quad (1.8.20)$$

Proof

Exponential generating functions can be used for an elegant proof. Exponential generating functions are the combinatorial equivalent of moment generating functions for discrete probability distributions on \mathbb{N} . So let G and H denote the exponential generating functions of the sequences \mathbf{a} and \mathbf{b} , respectively. Then

$$\begin{aligned} H(x) &= \sum_{n=0}^{\infty} \frac{b_n}{n!} x^n = \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{k=0}^n \binom{n}{k} a_k x^n = \sum_{k=0}^{\infty} \sum_{n=k}^{\infty} \frac{1}{n!} \frac{n!}{k!(n-k)!} a_k x^n \\ &= \sum_{k=0}^{\infty} \frac{1}{k!} a_k x^k \sum_{n=k}^{\infty} \frac{1}{(n-k)!} x^{n-k} = e^x \sum_{k=0}^{\infty} \frac{1}{k!} a_k x^k = e^x G(x) \end{aligned}$$

So it follows that

$$\begin{aligned} G(x) &= e^{-x} H(x) = \sum_{k=0}^{\infty} \frac{1}{k!} b_k x^k \sum_{n=k}^{\infty} \frac{1}{(n-k)!} (-1)^{n-k} x^{n-k} \\ &= \sum_{k=0}^{\infty} \sum_{n=k}^{\infty} \frac{1}{n!} \frac{n!}{k!(n-k)!} (-1)^{n-k} b_k x^n = \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{k=0}^n \binom{n}{k} (-1)^{n-k} b_k x^n \end{aligned}$$

But by definition,

$$G(x) = \sum_{n=0}^{\infty} \frac{a_n}{n!} x^n \quad (1.8.21)$$

and so the inverse formula follows.

Samples

The experiment of drawing a sample from a population is basic and important. There are two essential attributes of samples: whether or not *order* is important, and whether or not a sampled object is *replaced* in the population before the next draw. Suppose now that the population D contains n objects and we are interested in drawing a sample of k objects. Let's review what we know so far:

- If order is important and sampled objects are replaced, then the samples are just elements of the product set D^k . Hence, the number of samples is n^k .
- If order is important and sample objects are not replaced, then the samples are just permutations of size k chosen from D . Hence the number of samples is $n^{(k)}$.
- If order is not important and sample objects are not replaced, then the samples are just combinations of size k chosen from D . Hence the number of samples is $\binom{n}{k}$.

Thus, we have one case left to consider.

Unordered Samples With Replacement

An unordered sample chosen *with* replacement from D is called a *multiset*. A multiset is like an ordinary set except that elements may be repeated.

There is a one-to-one correspondence between each pair of the following collections:

1. Multisets of size k from a population D of n elements.
2. Bit strings of length $n + k - 1$ with exactly k 1s.
3. Nonnegative integer solutions (x_1, x_2, \dots, x_n) of the equation $x_1 + x_2 + \dots + x_n = k$.

Each of these collections has $\binom{n+k-1}{k}$ members.

Proof

Suppose that $D = \{d_1, d_2, \dots, d_n\}$. Consider a multiset of size k . Since order does not matter, we can list all of the occurrences of d_1 (if any) first, then the occurrences of d_2 (if any), and so forth, until we at last list the occurrences of d_n (if any). If we know we are using this data structure, we don't actually have to list the actual elements, we can simply use 1 as a placeholder with 0 as a separator. In the resulting bit string, 1 occurs k times and 0 occurs $n - 1$ times. Conversely, any such bit string uniquely defines a multiset of size k . Next, given a multiset of size k from D , let x_i denote the number of times that d_i occurs, for $i \in \{1, 2, \dots, n\}$. Then (x_1, x_2, \dots, x_n) satisfies the conditions in (c). Conversely, any solution to the equation in (c) uniquely defines a multiset of size k from D . We already know how to count the collection in (b): the number of bit strings of length $n + k - 1$ with 1 occurring k times is $\binom{n+k-1}{k} = \binom{n+k-1}{n-1}$.

Summary of Sampling Formulas

The following table summarizes the formulas for the number of samples of size k chosen from a population of n elements, based on the criteria of order and replacement.

Sampling formulas

Number of Samples	With order	Without
With replacement	n^k	$\binom{n+k-1}{k}$
Without	$n^{(k)}$	$\binom{n}{k}$

Multinomial Coefficients

Partitions of a Set

Recall that the binomial coefficient $\binom{n}{j}$ is the number of subsets of size j from a set S of n elements. Note also that when we select a subset A of size j from S , we effectively *partition* S into two disjoint subsets of sizes j and $n - j$, namely A and A^c . A natural generalization is to *partition* S into a union of k distinct, pairwise disjoint subsets (A_1, A_2, \dots, A_k) where $\#(A_i) = n_i$ for each $i \in \{1, 2, \dots, k\}$. Of course we must have $n_1 + n_2 + \dots + n_k = n$.

The number of ways to partition a set of n elements into a sequence of k sets of sizes (n_1, n_2, \dots, n_k) is

$$\binom{n}{n_1} \binom{n-n_1}{n_2} \dots \binom{n-n_1-\dots-n_{k-1}}{n_k} = \frac{n!}{n_1! n_2! \dots n_k!} \quad (1.8.22)$$

Proof

The left side follows from the multiplication rule. There are $\binom{n}{n_1}$ ways to select the first set in the partition, $\binom{n-n_1}{n_2}$ ways to select the second set in the partition, and so forth. The right side follows by writing the binomial coefficients on the left in terms of factorials and simplifying.

The number in (18) is called a *multinomial coefficient* and is denoted by

$$\binom{n}{n_1, n_2, \dots, n_k} = \frac{n!}{n_1! n_2! \dots n_k!} \quad (1.8.23)$$

If $n, k \in \mathbb{N}$ with $k \leq n$ then

$$\binom{n}{k, n-k} = \binom{n}{k} \quad (1.8.24)$$

Combinatorial Proof

As noted before, if we select a subset of size k from an n element set, then we partition the set into two subsets of sizes k and $n-k$.

Sequences

Consider now the set $T = \{1, 2, \dots, k\}^n$. Elements of this set are sequences of length n in which each coordinate is one of k values. Thus, these sequences generalize the bit strings of length n . Again, let (n_1, n_2, \dots, n_k) be a sequence of nonnegative integers with $\sum_{i=1}^k n_i = n$.

There is a one-to-one correspondence between the following collections:

1. Partitions of S into pairwise disjoint subsets (A_1, A_2, \dots, A_k) where $\#(A_j) = n_j$ for each $j \in \{1, 2, \dots, k\}$.
2. Sequences in $\{1, 2, \dots, k\}^n$ in which j occurs n_j times for each $j \in \{1, 2, \dots, k\}$.

Proof

Suppose that $S = \{s_1, s_2, \dots, s_n\}$. A one-to-one correspondence between a partition (A_1, A_2, \dots, A_k) of the type in (a) and a sequence $\mathbf{x} = (x_1, x_2, \dots, x_n)$ of the type in (b) can be constructed by the rule that $s_i \in A_j$ if and only if $x_i = j$.

It follows that the number of elements in both of these collections is

$$\binom{n}{n_1, n_2, \dots, n_k} = \frac{n!}{n_1! n_2! \dots n_k!} \quad (1.8.25)$$

Permutations with Indistinguishable Objects

Suppose now that we have n object of k different types, with n_i elements of type i for each $i \in \{1, 2, \dots, k\}$. Moreover, objects of a given type are considered identical. There is a one-to-one correspondence between the following collections:

1. Sequences in $\{1, 2, \dots, k\}^n$ in which j occurs n_j times for each $j \in \{1, 2, \dots, k\}$.
2. Distinguishable permutations of the n objects.

Proof

A one-to-one correspondence between a sequence $\mathbf{x} = (x_1, x_2, \dots, x_n)$ of the type in (a) and a permutation of the n objects can be constructed by the rule that we put an object of type j in position i if and only if $x_i = j$.

Once again, it follows that the number of elements in both collections is

$$\binom{n}{n_1, n_2, \dots, n_k} = \frac{n!}{n_1! n_2! \dots n_k!} \quad (1.8.26)$$

The Multinomial Theorem

The following result is the *multinomial theorem* which is the reason for the name of the coefficients.

If $x_1, x_2, \dots, x_k \in \mathbb{R}$ and $n \in \mathbb{N}$ then

$$(x_1 + x_2 + \cdots + x_k)^n = \sum \binom{n}{n_1, n_2, \dots, n_k} x_1^{n_1} x_2^{n_2} \cdots x_k^{n_k} \quad (1.8.27)$$

The sum is over sequences of nonnegative integers (n_1, n_2, \dots, n_k) with $n_1 + n_2 + \cdots + n_k = n$. There are $\binom{n+k-1}{n}$ terms in this sum.

Combinatorial Proof

Note that to get $x_1^{n_1} x_2^{n_2} \cdots x_k^{n_k}$ in the expansion of $(x_1 + x_2 + \cdots + x_k)^n$, we must choose x_i in n_i of the factors, for each i . The number of ways to do this is the multinomial coefficient $\binom{n}{n_1, n_2, \dots, n_k}$. The number of terms in the sum follows from the [formula above](#).

Computational Exercises

Arrangements

In a race with 10 horses, the first, second, and third place finishers are noted. How many outcomes are there?

Answer

720

Eight persons, consisting of four male-female couples, are to be seated in a row of eight chairs. How many seating arrangements are there in each of the following cases:

1. There are no other restrictions.
2. The men must sit together and the women must sit together.
3. The men must sit together.
4. Each couple must sit together.

Answer

1. 40 320
2. 1152
3. 2880
4. 384

Suppose that n people are to be seated at a round table. How many seating arrangements are there? The mathematical significance of a round table is that there is no dedicated *first* chair.

Answer

$(n - 1)!$. Seat one, distinguished person arbitrarily. Every seating arrangement can then be specified by giving the position of a person (say clockwise) relative to the distinguished person.

Twelve books, consisting of 5 math books, 4 science books, and 3 history books are arranged on a bookshelf. Find the number of arrangements in each of the following cases:

1. There are no restrictions.
2. The books of each type must be together.
3. The math books must be together.

Answer

1. 479 001 600
2. 103 680
3. 4 838 400

Find the number of distinct arrangements of the letters in each of the following words:

1. statistics
2. probability

3. mississippi
4. tennessee
5. alabama

Answer

1. 50 400
2. 9 979 200
3. 34 650
4. 3780
5. 210

A child has 12 blocks; 5 are red, 4 are green, and 3 are blue. In how many ways can the blocks be arranged in a line if blocks of a given color are considered identical?

Answer

27 720

Code Words

A license tag consists of 2 capital letters and 5 digits. Find the number of tags in each of the following cases:

1. There are no other restrictions
2. The letters and digits are all different.

Answer

1. 67 600 000
2. 19 656 000

Committees

A club has 20 members; 12 are women and 8 are men. A committee of 6 members is to be chosen. Find the number of different committees in each of the following cases:

1. There are no other restrictions.
2. The committee must have 4 women and 2 men.
3. The committee must have at least 2 women and at least 2 men.

Answer

1. 38 760
2. 13 860
3. 30 800

Suppose that a club with 20 members plans to form 3 distinct committees with 6, 5, and 4 members, respectively. In how many ways can this be done.

Answer

9 777 287 520 Note that the members *not* on a committee also form one of the sets in the partition.

Cards

A standard *card deck* can be modeled by the Cartesian product set

$$D = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, j, q, k\} \times \{\clubsuit, \diamondsuit, \heartsuit, \spadesuit\} \quad (1.8.28)$$

where the first coordinate encodes the *denomination* or *kind* (ace, 2-10, jack, queen, king) and where the second coordinate encodes the *suit* (clubs, diamonds, hearts, spades). Sometimes we represent a card as a *string* rather than an ordered pair (for example $q\heartsuit$).

A *poker hand* (in draw poker) consists of 5 cards dealt without replacement and without regard to order from a deck of 52 cards. Find the number of poker hands in each of the following cases:

1. There are no restrictions.
2. The hand is a *full house* (3 cards of one kind and 2 of another kind).
3. The hand has *4 of a kind*.
4. The cards are all in the same suit (so the hand is a *flush* or a *straight flush*).

Answer

1. 2 598 960
2. 3744
3. 624
4. 5148

The game of **poker** is studied in detail in the chapter on Games of Chance.

A *bridge hand* consists of 13 cards dealt without replacement and without regard to order from a deck of 52 cards. Find the number of bridge hands in each of the following cases:

1. There are no restrictions.
2. The hand has exactly 4 spades.
3. The hand has exactly 4 spades and 3 hearts.
4. The hand has exactly 4 spades, 3 hearts, and 2 diamonds.

Answer

1. 635 013 559 600
2. 151 519 319 380
3. 47 079 732 700
4. 11 404 407 300

A hand of cards that has no cards in a particular suit is said to be *void* in that suit. Use the inclusion-exclusion formula to find each of the following:

1. The number of poker hands that are void in at least one suit.
2. The number of bridge hands that are void in at least one suit.

Answer

1. 1 913 496
2. 32 427 298 180

A bridge hand that has no *honor cards* (cards of denomination 10, jack, queen, king, or ace) is said to be a *Yarborough*, in honor of the Second Earl of Yarborough. Find the number of Yarboroughs.

Answer

347 373 600

A *bridge deal* consists of dealing 13 cards (a *bridge hand*) to each of 4 distinct players (generically referred to as *north*, *south*, *east*, and *west*) from a standard deck of 52 cards. Find the number of bridge deals.

Answer

$53\,644\,737\,765\,488\,792\,839\,237\,440\,000 \approx 5.36 \times 10^{28}$

This staggering number is about the same order of magnitude as the number of atoms in your body, and is one of the reasons that bridge is a rich and interesting game.

Find the number of permutations of the cards in a standard deck.

Answer

$52! \approx 8.0658 \times 10^{67}$

This number is even more staggering. Indeed if you perform the experiment of dealing all 52 cards from a well-shuffled deck, you may well generate a pattern of cards that has never been generated before, thereby ensuring your immortality. Actually, this experiment shows that, in a sense, rare events can be very common. By the way, Persi Diaconis has shown that it takes about seven standard riffle shuffles to thoroughly randomize a deck of cards.

Dice and Coins

Suppose that 5 distinct, standard dice are rolled and the sequence of scores recorded.

1. Find the number of sequences.
2. Find the number of sequences with the scores all different.

Answer

1. 7776
2. 720

Suppose that 5 identical, standard dice are rolled. How many outcomes are there?

Answer

252

A coin is tossed 10 times and the outcome is recorded as a bit string (where 1 denotes heads and 0 tails).

1. Find the number of outcomes.
2. Find the number of outcomes with exactly 4 heads.
3. Find the number of outcomes with at least 8 heads.

Answer

1. 1024
2. 210
3. 56

Polynomial Coefficients

Find the coefficient of $x^3 y^4$ in $(2x - 4y)^7$.

Answer

71 680

Find the coefficient of x^5 in $(2 + 3x)^8$.

Answer

108 864

Find the coefficient of $x^3 y^7 z^5$ in $(x + y + z)^{15}$.

Answer

360 360

The Galton Board

In the Galton board game,

1. Move the ball from $(0, 0)$ to $(10, 6)$ along a path of your choice. Note the corresponding bit string and subset.
2. Generate the bit string 0011101001. Note the corresponding subset and path.
3. Generate the subset $\{1, 4, 5, 7, 8, 10\}$. Note the corresponding bit string and path.
4. Generate all paths from $(0, 0)$ to $(5, 3)$. How many paths are there?

Answer

4. 10

Generate Pascal's triangle up to $n = 10$.

Samples

A shipment contains 12 good and 8 defective items. A sample of 5 items is selected. Find the number of samples that contain exactly 3 good items.

Answer

6160

In the (n, k) lottery, k numbers are chosen without replacement from the set of integers from 1 to n (where $n, k \in \mathbb{N}_+$ and $k < n$). Order does not matter.

1. Find the number of outcomes in the general (n, k) lottery.
2. Explicitly compute the number of outcomes in the $(44, 6)$ lottery (a common format).

Answer

1. $\binom{n}{k}$
2. 7 059 052

For more on this topic, see the section on [Lotteries](#) in the chapter on Games of Chance.

Explicitly compute each formula in the [sampling table](#) above when $n = 10$ and $k = 4$.

Answer

1. Ordered samples with replacement: 10 000
2. Ordered samples without replacement: 5040
3. Unordered samples with replacement: 715
4. Unordered samples without replacement: 210

Greetings

Suppose there are n people who shake hands with each other. How many handshakes are there?

Answer

$\binom{n}{2}$. Note that a handshake can be thought of as a subset of size 2 from the set of n people.

There are m men and n women. The men shake hands with each other; the women hug each other; and each man bows to each woman.

1. How many handshakes are there?
2. How many hugs are there?
3. How many bows are there?
4. How many greetings are there?

Answer

1. $\binom{m}{2}$
2. $\binom{n}{2}$
3. mn
4. $\binom{m}{2} + \binom{n}{2} + mn = \binom{m+n}{2}$

Integer Solutions

Find the number of integer solutions of $x_1 + x_2 + x_3 = 10$ in each of the following cases:

1. $x_i \geq 0$ for each i .

2. $x_i > 0$ for each i .

Answer

1. 66
2. 36

Generalized Coefficients

Compute each of the following:

1. $(-5)^{(3)}$
2. $(\frac{1}{2})^{(4)}$
3. $(-\frac{1}{3})^{(5)}$

Answer

1. -210
2. $-\frac{15}{16}$
3. $-\frac{3640}{243}$

Compute each of the following:

1. $(\frac{1/2}{3})$
2. $(\frac{-5}{4})$
3. $(\frac{-1/3}{5})$

Answer

1. $\frac{1}{16}$
2. 70
3. $-\frac{91}{729}$

Birthdays

Suppose that n persons are selected and their birthdays noted. (Ignore leap years, so that a year has 365 days.)

1. Find the number of outcomes.
2. Find the number of outcomes with distinct birthdays.

Answer

1. 365^n .
2. $365^{(n)}$.

Chess

Note that the squares of a chessboard are distinct, and in fact are often identified with the Cartesian product set

$$\{a, b, c, d, e, f, g, h\} \times \{1, 2, 3, 4, 5, 6, 7, 8\} \quad (1.8.29)$$

Find the number of ways of placing 8 rooks on a chessboard so that no rook can capture another in each of the following cases.

1. The rooks are distinguishable.
2. The rooks are indistinguishable.

Answer

1. 1 625 702 400
2. 40 320

Gifts

Suppose that 20 identical candies are distributed to 4 children. Find the number of distributions in each of the following cases:

1. There are no restrictions.
2. Each child must get at least one candy.

Answer

1. 1771
2. 969

In the song *The Twelve Days of Christmas*, find the number of gifts given to the singer by her true love. (Note that the singer starts afresh with gifts each day, so that for example, the true love gets a new partridge in a pear tree each of the 12 days.)

Answer

364

Teams

Suppose that 10 kids are divided into two teams of 5 each for a game of basketball. In how many ways can this be done in each of the following cases:

1. The teams are distinguishable (for example, one team is labeled “Alabama” and the other team is labeled “Auburn”).
2. The teams are not distinguishable.

Answer

1. 252
2. 126

This page titled [1.8: Combinatorial Structures](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

1.9: Topological Spaces

Topology is one of the major branches of mathematics, along with other such branches as algebra (in the broad sense of algebraic structures), and analysis. Topology deals with spatial concepts involving distance, closeness, separation, convergence, and continuity. Needless to say, entire series of books have been written about the subject. Our goal in this section and the next is simply to review the basic definitions and concepts of topology that we will need for our study of probability and stochastic processes. You may want to refer to this section as needed.

Basic Theory

Definitions

A *topological space* consists of a nonempty set S and a collection \mathcal{S} of subsets of S that satisfy the following properties:

1. $S \in \mathcal{S}$ and $\emptyset \in \mathcal{S}$
2. If $\mathcal{A} \subseteq \mathcal{S}$ then $\bigcup \mathcal{A} \in \mathcal{S}$
3. If $\mathcal{A} \subseteq \mathcal{S}$ and \mathcal{A} is finite, then $\bigcap \mathcal{A} \in \mathcal{S}$

If $A \in \mathcal{S}$, then A is said to be *open* and A^c is said to be *closed*. The collection \mathcal{S} of open sets is a *topology* on S .

So the union of an arbitrary number of open sets is still open, as is the intersection of a finite number of open sets. The universal set S and the empty set \emptyset are both open and closed. There may or may not exist other subsets of S with this property.

Suppose that S is a nonempty set, and that \mathcal{S} and \mathcal{T} are topologies on S . If $\mathcal{S} \subseteq \mathcal{T}$ then \mathcal{T} is *finer* than \mathcal{S} , and \mathcal{S} is *coarser* than \mathcal{T} . *Coarser than* defines a partial order on the collection of topologies on S . That is, if \mathcal{R} , \mathcal{S} , \mathcal{T} are topologies on S then

1. \mathcal{R} is coarser than \mathcal{R} , the *reflexive property*.
2. If \mathcal{R} is coarser than \mathcal{S} and \mathcal{S} is coarser than \mathcal{R} then $\mathcal{R} = \mathcal{S}$, the *anti-symmetric property*.
3. If \mathcal{R} is coarser than \mathcal{S} and \mathcal{S} is coarser than \mathcal{T} then \mathcal{R} is coarser than \mathcal{T} , the *transitive property*.

A topology can be characterized just as easily by means of closed sets as open sets.

Suppose that S is a nonempty set. A collection of subsets \mathcal{C} is the collection of closed sets for a topology on S if and only if

1. $S \in \mathcal{C}$ and $\emptyset \in \mathcal{C}$
2. If $\mathcal{A} \subseteq \mathcal{C}$ then $\bigcap \mathcal{A} \in \mathcal{C}$.
3. If $\mathcal{A} \subseteq \mathcal{C}$ and \mathcal{A} is a finite then $\bigcup \mathcal{A} \in \mathcal{C}$.

Proof

The set $\mathcal{S} = \{A^c : A \in \mathcal{C}\}$ must satisfy the axioms of a topology. So the result follows DeMorgan's laws: if \mathcal{A} is a collection of subsets of S then

$$\begin{aligned} \left(\bigcup \mathcal{A}\right)^c &= \bigcap \{A^c : A \in \mathcal{A}\} \\ \left(\bigcap \mathcal{A}\right)^c &= \bigcup \{A^c : A \in \mathcal{A}\} \end{aligned}$$

Suppose that (S, \mathcal{S}) is a topological space, and that $x \in S$. A set $A \subseteq S$ is a *neighborhood* of x if there exists $U \in \mathcal{S}$ with $x \in U \subseteq A$.

So a neighborhood of a point $x \in S$ is simply a set with an open subset that contains x . The idea is that points in a “small” neighborhood of x are “close” to x in a sense. An open set can be defined in terms of the neighborhoods of the points in the set.

Suppose again that (S, \mathcal{S}) is a topological space. A set $U \subseteq S$ is open if and only if U is a neighborhood of every $x \in U$

Proof

If U is open, then clearly U is a neighborhood of every point $x \in U$ and clearly satisfies the condition in the theorem. Conversely, suppose that U is a neighborhood of every $x \in U$. Then by definition of neighborhood, for every $x \in U$ there exists an open set U_x with $x \in U_x \subseteq U$. But then $\bigcup_{x \in U} U_x$ is open, and clearly this set is U .

Although the proof seems trivial, the neighborhood concept is how you should think of openness. A set U is open if every point in U has a set of “nearby points” that are also in U .

Our next three definitions deal with *topological* sets that are naturally associated with a given subset.

Suppose again that (S, \mathcal{S}) is a topological space and that $A \subseteq S$. The *closure* of A is the set

$$\text{cl}(A) = \bigcap \{B \subseteq S : B \text{ is closed and } A \subseteq B\} \quad (1.9.1)$$

This is the smallest closed set containing A :

1. $\text{cl}(A)$ is closed.
2. $A \subseteq \text{cl}(A)$.
3. If B is closed and $A \subseteq B$ then $\text{cl}(A) \subseteq B$

Proof

Note that $\mathcal{B} = \{B \subseteq S : B \text{ is closed and } A \subseteq B\}$ is nonempty since $S \in \mathcal{B}$.

1. The sets in \mathcal{B} are closed so $\bigcap \mathcal{B}$ is closed.
2. By definition, $A \subseteq B$ for each $B \in \mathcal{B}$. Hence $A \subseteq \bigcap \mathcal{B}$.
3. If B is closed and $A \subseteq B$ then $B \in \mathcal{B}$ so $\bigcap \mathcal{B} \subseteq B$.

Of course, if A is closed then $A = \text{cl}(A)$. Complementary to the closure of a set is the interior of the set.

Suppose again that (S, \mathcal{S}) is a topological space and that $A \subseteq S$. The *interior* of A is the set

$$\text{int}(A) = \bigcup \{U \subseteq S : U \text{ is open and } U \subseteq A\} \quad (1.9.2)$$

This set is the largest open subset of A :

1. $\text{int}(A)$ is open.
2. $\text{int}(A) \subseteq A$.
3. If U is open and $U \subseteq A$ then $U \subseteq \text{int}(A)$

Proof

Note that $\mathcal{U} = \{U \subseteq S : U \text{ is open and } U \subseteq A\}$ is nonempty since $\emptyset \in \mathcal{U}$.

1. The sets in \mathcal{U} are open so $\bigcup \mathcal{U}$ is open.
2. By definition, $U \subseteq A$ for each $U \in \mathcal{U}$. Hence $\bigcup \mathcal{U} \subseteq A$.
3. If U is open and $U \subseteq A$ then $U \in \mathcal{U}$ so $U \subseteq \bigcup \mathcal{U}$.

Of course, if A is open then $A = \text{int}(A)$. The boundary of a set is the set difference between the closure and the interior.

Suppose again that (S, \mathcal{S}) is a topological space. The *boundary* of A is $\partial(A) = \text{cl}(A) \setminus \text{int}(A)$. This set is closed.

Proof

By definition, $\partial(A) = \text{cl}(A) \cap [\text{int}(A)]^c$, the intersection of two closed sets.

A topology on a set induces a natural topology on any subset of the set.

Suppose that (S, \mathcal{S}) is a topological space and that R is a nonempty subset of S . Then $\mathcal{R} = \{A \cap R : A \in \mathcal{S}\}$ is a topology on R , known as the *relative topology* induced by \mathcal{S} .

Proof

First $S \in \mathcal{S}$ and $S \cap R = R$, so $R \in \mathcal{R}$. Next, $\emptyset \in \mathcal{S}$ and $\emptyset \cap R = \emptyset$ so $\emptyset \in \mathcal{R}$. Suppose that $\mathcal{B} \subseteq \mathcal{R}$. For each $B \in \mathcal{B}$, select $A \in \mathcal{S}$ such that $B = A \cap R$. Let \mathcal{A} denote the collection of sets selected (we need the axiom of choice to do this).

Then $\bigcup \mathcal{A} \in \mathcal{S}$ and $\bigcup \mathcal{B} = (\bigcup \mathcal{A}) \cap R$, so $\bigcup \mathcal{B} \in \mathcal{R}$. Finally, suppose that $\mathcal{B} \subseteq \mathcal{R}$ is finite. Once again, for each $B \in \mathcal{B}$ there exists $A \in \mathcal{S}$ with $A \cap R = B$. Let \mathcal{A} denote the collection of sets selected. Then \mathcal{A} is finite so $\bigcap \mathcal{A} \in \mathcal{S}$. But $\bigcap \mathcal{B} = (\bigcap \mathcal{A}) \cap R$ so $\bigcap \mathcal{B} \in \mathcal{R}$.

In the context of the previous result, note that if R is itself open, then the relative topology is $\mathcal{R} = \{A \in \mathcal{S} : A \subseteq R\}$, the subsets of R that are open in the original topology.

Separation Properties

Separation properties refer to the ability to separate points or sets with disjoint open sets. Our first definition deals with separating two points.

Suppose that (S, \mathcal{S}) is a topological space and that x, y are distinct points in S . Then x and y can be *separated* if there exist disjoint open sets U and V with $x \in U$ and $y \in V$. If every pair of distinct points in S can be separated, then (S, \mathcal{S}) is called a *Hausdorff space*.

Hausdorff spaces are named for the German mathematician Felix Hausdorff. There are weaker separation properties. For example, there could be an open set U that contains x but not y , and an open set V that contains y but not x , but no disjoint open sets that contain x and y . Clearly if every open set that contains one of the points also contains the other, then the points are indistinguishable from a topological viewpoint. In a Hausdorff space, singletons are closed.

Suppose that (S, \mathcal{S}) is a Hausdorff space. Then $\{x\}$ is closed for each $x \in S$.

Proof

The definition shows immediately that $\{x\}^c$ is open: if $y \in \{x\}^c$, there exists an open set V with $y \in V \subseteq \{x\}^c$.

Our next definition deals with separating a point from a closed set.

Suppose again that (S, \mathcal{S}) is a topological space. A nonempty closed set $A \subseteq S$ and a point $x \in A^c$ can be *separated* if there exist disjoint open sets U and V with $A \subseteq U$ and $x \in V$. If every nonempty closed set A and point $x \in A^c$ can be separated, then the space (S, \mathcal{S}) is *regular*.

Clearly if (S, \mathcal{S}) is a regular space and singleton sets are closed, then (S, \mathcal{S}) is a Hausdorff space.

Bases

Topologies, like other set structures, are often defined by first giving some basic sets that should belong to the collection, and then extending the collection so that the defining axioms are satisfied. This idea is motivation for the following definition:

Suppose again that (S, \mathcal{S}) is a topological space. A collection $\mathcal{B} \subseteq \mathcal{S}$ is a *base* for \mathcal{S} if every set in \mathcal{S} can be written as a union of sets in \mathcal{B} .

So, a base is a smaller collection of open sets with the property that every other open set can be written as a union of basic open sets. But again, we often want to start with the basic open sets and extend this collection to a topology. The following theorem gives the conditions under which this can be done.

Suppose that S is a nonempty set. A collection \mathcal{B} of subsets of S is a base for a topology on S if and only if

1. $S = \bigcup \mathcal{B}$
2. If $A, B \in \mathcal{B}$ and $x \in A \cap B$, there exists $C \in \mathcal{B}$ with $x \in C \subseteq A \cap B$

Proof

Suppose that \mathcal{B} is a base for a topology \mathcal{S} on S . Since S is open, S is a union of sets in \mathcal{B} . Since every set in \mathcal{B} is a subset of S , we must have $S = \bigcup \mathcal{B}$. Suppose that $A, B \in \mathcal{B}$ and that $x \in A \cap B$. Since $A \cap B$ is open, it's a union of sets in \mathcal{B} . The point x must be in one of those sets, so there exists $C \in \mathcal{B}$ with $x \in C \subseteq A \cap B$.

Suppose now that \mathcal{B} satisfies the two conditions in the theorem. Let \mathcal{S} be the collection of all unions of sets in \mathcal{B} . Then $S \in \mathcal{S}$ by condition (a), and $\emptyset \in \mathcal{S}$ by taking a vacuous union. Suppose that $U_i \in \mathcal{S}$ for $i \in I$ where I is an arbitrary index

set. Then for each $i \in I$, there exists an index set J_i such that $U_i = \bigcup_{j \in J_i} B_{i,j}$ where $B_{i,j} \in \mathcal{B}$ for each $j \in J_i$. But then

$$\bigcup_{i \in I} U_i = \bigcup_{i \in I} \bigcup_{j \in J_i} B_{i,j} \in \mathcal{S} \quad (1.9.3)$$

Finally, suppose that $U, V \in \mathcal{S}$. Then there exist index sets I and J with $U = \bigcup_{i \in I} A_i$ and $V = \bigcup_{j \in J} B_j$ where $A_i \in \mathcal{B}$ for all $i \in I$ and $B_j \in \mathcal{B}$ for all $j \in J$. Then

$$U \cap V = \bigcup_{i \in I, j \in J} (A_i \cap B_j) \quad (1.9.4)$$

By condition (b), for each $i \in I, j \in J$, and $x \in A_i \cap B_j$ there exists $C_{x,i,j} \in \mathcal{B}$ with $x \in C_{x,i,j} \subseteq A_i \cap B_j$. But then clearly

$$U \cap V = \bigcup \{C_{x,i,j} : i \in I, j \in J, x \in A_i \cap B_j\} \in \mathcal{S} \quad (1.9.5)$$

Here is a slightly weaker condition, but one that is often satisfied in practice.

Suppose that S is a nonempty set. A collection \mathcal{B} of subsets of S that satisfies the following properties is a base for a topology on S :

1. $S = \bigcup \mathcal{B}$
2. If $A, B \in \mathcal{B}$ then $A \cap B \in \mathcal{B}$

Part (b) means that \mathcal{B} is closed under finite intersections.

Compactness

Our next discussion considers another very important type of set. Some additional terminology will make the discussion easier. Suppose that S is a set and $A \subseteq S$. A collection of subsets \mathcal{A} of S is said to *cover* A if $A \subseteq \bigcup \mathcal{A}$. So the word *cover* simply means a collection of sets whose union contains a given set. In a topological space, we can have open an open cover (that is, a cover with open sets), a closed cover (that is, a cover with closed sets), and so forth.

Suppose again that (S, \mathcal{S}) is a topological space. A set $C \subseteq S$ is *compact* if every open cover of C has a finite sub-cover. That is, if $\mathcal{A} \subseteq \mathcal{S}$ with $C \subseteq \bigcup \mathcal{A}$ then there exists a finite $\mathcal{B} \subseteq \mathcal{A}$ with $C \subseteq \bigcup \mathcal{B}$.

So intuitively, a compact set is *compact* in the ordinary sense of the word. No matter how “small” are the open sets in the covering of C , there will always exist a finite number of the open sets that cover C .

Suppose again that (S, \mathcal{S}) is a topological space and that $C \subseteq S$ is a compact. If $B \subseteq C$ is closed, then B is also compact.

Proof

Suppose that \mathcal{A} is an open cover of B . Since B is closed, B^c is open, so $\mathcal{A} \cup \{B^c\}$ is an open cover of C . Since C is compact, this last collection has a finite sub-cover of C , which is also a finite sub-cover of B .

Compactness is also preserved under finite unions.

Suppose again that (S, \mathcal{S}) is a topological space, and that $C_i \subseteq S$ is compact for each i in a finite index set I . Then $C = \bigcup_{i \in I} C_i$ is compact.

Proof

Suppose that \mathcal{A} is an open cover of C . Then trivially, \mathcal{A} is also an open cover of C_i for each $i \in I$. Hence there exists a finite subcover $\mathcal{A}_i \subseteq \mathcal{A}$ of C_i for each $i \in I$. But then $\bigcup_{i \in I} \mathcal{A}_i$ is also finite and is a covering of C .

As we saw above, closed subsets of a compact set are themselves compact. In a Hausdorff space, a compact set is itself closed.

Suppose that (S, \mathcal{S}) is a Hausdorff space. If $C \subseteq S$ is compact then C is closed.

Proof

We will show that C^c is open, so fix $x \in C^c$. For each $y \in C$, the points x and y can be separated, so there exist disjoint open sets U_y and V_y such that $x \in U_y$ and $y \in V_y$. Trivially, the collection $\{V_y : y \in C\}$ is an open cover of C , and hence there exist a finite subset $B \subseteq C$ such that $\{V_y : y \in B\}$ covers C . But then $U = \bigcap_{y \in B} U_y$ is open and is disjoint from $\bigcup_{y \in B} V_y$. Hence also U is disjoint from C . So to summarize, U is open and $x \in U \subseteq C^c$.

Also in a Hausdorff space, a point can be separated from a compact set that does not contain the point.

Suppose that (S, \mathcal{S}) is a Hausdorff space. If $x \in S$, $C \subseteq S$ is compact, and $x \notin C$, then there exist disjoint open sets U and V with $x \in U$ and $C \subseteq V$.

Proof

Since the space is Hausdorff, for each $y \in C$ there exist disjoint open sets U_y and V_y with $x \in U_y$ and $y \in V_y$. The collection $\{V_y : y \in C\}$ is an open cover of C , and hence there exists a finite set $B \subseteq C$ such that $\{V_y : y \in B\}$ covers C . Thus let $U = \bigcap_{y \in B} U_y$ and $V = \bigcup_{y \in B} V_y$. Then U is open, since B is finite, and V is open. Moreover U and V are disjoint, and $x \in U$ and $C \subseteq V$.

In a Hausdorff space, if a point has a neighborhood with a compact boundary, then there is a smaller, closed neighborhood.

Suppose again that (S, \mathcal{S}) is a Hausdorff space. If $x \in S$ and A is a neighborhood of x with $\partial(A)$ compact, then there exists a closed neighborhood B of x with $B \subseteq A$.

Proof

By (20), there exist disjoint open sets U and V with $x \in U$ and $\partial(A) \subseteq V$. Hence $\text{cl}(U)$ and $\partial(A)$ are disjoint. Let $B = \text{cl}(A \cap U)$. Note that B is closed, and is a neighborhood of x since U and A are neighborhoods of x . Moreover,

$$B \subseteq \text{cl}(A) \cap \text{cl}(U) = [A \cup \partial(A)] \cap \text{cl}(U) = [A \cap \text{cl}(U)] \cup [\partial(A) \cap \text{cl}(U)] = A \cap \text{cl}(U) \subseteq A \quad (1.9.6)$$

Generally, *local* properties in a topological space refer to properties that hold on the neighborhoods of a point $x \in S$.

A topological space (S, \mathcal{S}) is *locally compact* if every point $x \in S$ has a compact neighborhood.

This definition is important because many of the topological spaces that occur in applications (like probability) are not compact, but are locally compact. Locally compact Hausdorff spaces have a number of nice properties. In particular, in a locally compact Hausdorff space, there are arbitrarily “small” compact neighborhoods of a point.

Suppose that (S, \mathcal{S}) is a locally compact Hausdorff space. If $x \in S$ and A is a neighborhood of x , then there exists a compact neighborhood B of x with $B \subseteq A$.

Proof

Since S is locally compact, there exists a compact neighborhood C of x . Hence $A \cap C$ is a neighborhood of x . Moreover, $\partial(A \cap C)$ is closed and is a subset of C and hence is compact. From (21), there exists a closed neighborhood B of x with $B \subseteq A \cap C$. Since B is closed and $B \subseteq C$, B is compact. Of course also, $B \subseteq A$.

Countability Axioms

Our next discussion concerns topologies that can be “countably constructed” in a certain sense. Such axioms limit the “size” of the topology in a way, and are often satisfied by important topological spaces that occur in applications. We start with an important preliminary definition.

Suppose that (S, \mathcal{S}) is a topological space. A set $D \subseteq S$ is *dense* if $U \cap D$ is nonempty for every nonempty $U \in \mathcal{S}$.

Equivalently, D is dense if every neighborhood of a point $x \in S$ contains an element of D . So in this sense, one can find elements of D “arbitrarily close” to a point $x \in S$. Of course, the entire space S is dense, but we are usually interested in topological spaces that have dense sets of limited cardinality.

Suppose again that (S, \mathcal{S}) is a topological space. A set $D \subseteq S$ is dense if and only if $\text{cl}(D) = S$.

Proof

Suppose that D is dense. Since $\text{cl}(D)$ is closed, $[\text{cl}(D)]^c$ is open. If this set is nonempty, it must contain a point in D . But that's clearly a contradiction since $D \subseteq \text{cl}(D)$. Conversely, suppose that $\text{cl}(D) = S$. Suppose that U is a nonempty, open set. Then U^c is closed, and $U^c \neq S$. If $D \cap U = \emptyset$, then $D \subseteq U^c$. But then $\text{cl}(D) \subseteq U^c$ so $\text{cl}(D) \neq S$.

Here is our first countability axiom:

A topological space (S, \mathcal{S}) is *separable* if there exists a countable dense subset.

So in a separable space, there is a *countable* set D with the property that there are points in D “arbitrarily close” to every $x \in S$. Unfortunately, the term *separable* is similar to *separating points* that we discussed above in the definition of a Hausdorff space. But clearly the concepts are very different. Here is another important countability axiom.

A topological space (S, \mathcal{S}) is *second countable* if it has a countable base.

So in a second countable space, there is a countable collection of open sets \mathcal{B} with the property that every other open set is a union of sets in \mathcal{B} . Here is how the two properties are related:

If a topological space (S, \mathcal{S}) is second countable then it is separable.

Proof

Suppose that $\mathcal{B} = \{U_i : i \in I\}$ is a base for \mathcal{S} , where I is a countable index set. Select $x_i \in U_i$ for each $i \in I$, and let $D = \{x_i : i \in I\}$. Of course, D is countable. If U is open and nonempty, then $U = \bigcup_{j \in J} U_j$ for some nonempty $J \subseteq I$. But then $\{x_j : j \in J\} \subseteq U$, so D is dense.

As the terminology suggests, there are other axioms of countability (such as *first countable*), but the two we have discussed are the most important.

Connected and Disconnected Spaces

This discussion deals with the situation in which a topological space falls into two or more separated pieces, in a sense.

A topological space (S, \mathcal{S}) is *disconnected* if there exist nonempty, disjoint, open sets U and V with $S = U \cup V$. If (S, \mathcal{S}) is not disconnected, then it is *connected*.

Since $U = V^c$, it follows that U and V are also closed. So the space is disconnected if and only if there exists a proper subset U that is open and closed (sadly, such sets are sometimes called *clopen*). If S is disconnected, then S consists of two pieces U and V , and the points in U are not “close” to the points in V , in a sense. To study S topologically, we could simply study U and V separately, with their relative topologies.

Convergence

There is a natural definition for a convergent sequence in a topological space, but the concept is not as useful as one might expect.

Suppose again that (S, \mathcal{S}) is a topological space. A sequence of points $(x_n : n \in \mathbb{N}_+)$ in S *converges* to $x \in S$ if for every neighborhood A of x there exists $m \in \mathbb{N}_+$ such that $x_n \in A$ for $n > m$. We write $x_n \rightarrow x$ as $n \rightarrow \infty$.

So for every neighborhood of x , regardless of how “small”, all but finitely many of the terms of the sequence will be in the neighborhood. One would naturally hope that limits, when they exist, are unique, but this will only be the case if points in the space can be separated.

Suppose that (S, \mathcal{S}) is a Hausdorff space. If $(x_n : n \in \mathbb{N}_+)$ is a sequence of points in S with $x_n \rightarrow x \in S$ as $n \rightarrow \infty$ and $x_n \rightarrow y \in S$ as $n \rightarrow \infty$, then $x = y$.

Proof

If $x \neq y$, there exist disjoint neighborhoods A and B of x and y , respectively. There exist $k, m \in \mathbb{N}_+$ such that $x_n \in A$ for all $n > k$ and $x_n \in B$ for all $n > m$. But then if $n > \max\{k, m\}$, $x_n \in A$ and $x_n \in B$, a contradiction.

On the other hand, if distinct points $x, y \in S$ cannot be separated, then any sequence that converges to x will also converge to y .

Continuity

Continuity of functions is one of the most important concepts to come out of general topology. The idea, of course, is that if two points are close together in the domain, then the functional values should be close together in the range. The abstract topological definition, based on inverse images is very simple, but not very intuitive at first.

Suppose that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces. A function $f : S \rightarrow T$ is *continuous* if $f^{-1}(A) \in \mathcal{S}$ for every $A \in \mathcal{T}$.

So a continuous function has the property that the inverse image of an open set (in the range space) is also open (in the domain space). Continuity can equivalently be expressed in terms of closed subsets.

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces. A function $f : S \rightarrow T$ is continuous if and only if $f^{-1}(A)$ is a closed subset of S for every closed subset A of T .

Proof

Recall that $f^{-1}(A^c) = [f^{-1}(A)]^c$ for $A \subseteq T$. The result follows directly from the definition and the fact that a set is open if and only if its complement is closed.

Continuity preserves limits.

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces, and that $f : S \rightarrow T$ is continuous. If $(x_n : n \in \mathbb{N}_+)$ is a sequence of points in S with $x_n \rightarrow x \in S$ as $n \rightarrow \infty$, then $f(x_n) \rightarrow f(x)$ as $n \rightarrow \infty$.

Proof

Suppose that $V \subseteq T$ is open and $f(x) \in V$. Then $f^{-1}(V)$ is open in S and $x \in f^{-1}(V)$. Hence there exists $m \in \mathbb{N}_+$ such that $x_n \in f^{-1}(V)$ for every $n > m$. But then $f(x_n) \in V$ for $n > m$. So $f(x_n) \rightarrow f(x)$ as $n \rightarrow \infty$.

The converse of the last result is not true, so continuity of functions in a general topological space cannot be characterized in terms of convergent sequences. There are objects like sequences but more general, known as *nets*, that do characterize continuity, but we will not study these. Composition, the most important way to combine functions, preserves continuity.

Suppose that (S, \mathcal{S}) , (T, \mathcal{T}) , and (U, \mathcal{U}) are topological spaces. If $f : S \rightarrow T$ and $g : T \rightarrow U$ are continuous, then $g \circ f : S \rightarrow U$ is continuous.

Proof

If A is open in U then $g^{-1}(A)$ is open in T and therefore $f^{-1}[g^{-1}(A)] = (f^{-1} \circ g^{-1})(A)$ is open in S . But $(g \circ f)^{-1} = f^{-1} \circ g^{-1}$.

The next definition is very important. A recurring theme in mathematics is to recognize when two mathematical structures of a certain type are fundamentally the same, even though they may appear to be different.

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces. A one-to-one function f that maps S onto T with both f and f^{-1} continuous is a *homeomorphism* from (S, \mathcal{S}) to (T, \mathcal{T}) . When such a function exists, the topological spaces are said to be *homeomorphic*.

Note that in this definition, f^{-1} refers to the inverse function, not the mapping of inverse images. If f is a homeomorphism, then A is open in S if and only if $f(A)$ is open in T . It follows that the topological spaces are essentially equivalent: any purely topological property can be characterized in terms of open sets and therefore any such property is shared by the two spaces.

Being homeomorphic is an equivalence relation on the collection of topological spaces. That is, for spaces (S, \mathcal{S}) , (T, \mathcal{T}) , and (U, \mathcal{U}) ,

1. (S, \mathcal{S}) is homeomorphic to (S, \mathcal{S}) (the *reflexive property*).
2. If (S, \mathcal{S}) is homeomorphic to (T, \mathcal{T}) then (T, \mathcal{T}) is homeomorphic to (S, \mathcal{S}) (the *symmetric property*).

3. If (S, \mathcal{S}) is homeomorphic to (T, \mathcal{T}) and (T, \mathcal{T}) is homeomorphic to (U, \mathcal{U}) then (S, \mathcal{S}) is homeomorphic to (U, \mathcal{U}) (the *transitive property*).

Proof

1. The identity function $I : S \rightarrow S$ defined by $I(x) = x$ for $x \in S$ is a homeomorphism from the space (S, \mathcal{S}) to itself.
2. If f is a homeomorphism from (S, \mathcal{S}) to (T, \mathcal{T}) then f^{-1} is a homeomorphism from (T, \mathcal{T}) to (S, \mathcal{S}) .
3. If f is a homeomorphism from (S, \mathcal{S}) to (T, \mathcal{T}) and g is a homeomorphism from (T, \mathcal{T}) to (U, \mathcal{U}) , then $g \circ f$ is a homeomorphism from (S, \mathcal{S}) to (U, \mathcal{U}) .

Continuity can also be defined *locally*, by restricting attention to the neighborhoods of a point.

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces, and that $x \in S$. A function $f : S \rightarrow T$ is *continuous at x* if $f^{-1}(B)$ is a neighborhood of x in S whenever B is a neighborhood of $f(x)$ in T . If $A \subseteq S$, then f is *continuous on A* if f is continuous at each $x \in A$.

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces, and that $f : S \rightarrow T$. Then f is continuous if and only if f is continuous at each $x \in S$.

Proof

Suppose that f is continuous. Let $x \in S$ and let B be a neighborhood of $f(x)$. Then there exists an open set V in T with $f(x) \in V \subseteq B$. But then $f^{-1}(V)$ is open in S , and $x \in f^{-1}(V) \subseteq f^{-1}(B)$, so $f^{-1}(B)$ is a neighborhood of x . Hence f is continuous at x .

Conversely, suppose that f is continuous at each $x \in S$, and suppose that $V \in \mathcal{T}$. If V contains no points in the range of f , then $f^{-1}(V) = \emptyset \in \mathcal{S}$. Otherwise, there exists $x \in S$ with $f(x) \in V$. But then V is a neighborhood of $f(x)$, so $U = f^{-1}(V)$ is a neighborhood of x . Let $y \in U$. Then $f(y) \in V$ also, so U is also a neighborhood of y . Hence $U \in \mathcal{S}$.

Properties that are defined for a topological space can be applied to a subset of the space, with the relative topology. But one has to be careful.

Suppose again that (S, \mathcal{S}) are topological spaces and that $f : S \rightarrow T$. Suppose also that $A \subseteq S$, and let \mathcal{A} denote the relative topology on A induced by \mathcal{S} , and let f_A denote the restriction of f to A . If f is continuous on A then f_A is continuous relative to the spaces (A, \mathcal{A}) and (T, \mathcal{T}) . The converse is not generally true.

Proof

Suppose that $V \in \mathcal{T}$. If $f(A) \cap V = \emptyset$ then $f_A^{-1}(V) = \emptyset \in \mathcal{A}$. Otherwise, suppose there exists $x \in A$ with $f(x) \in V$. Then V is a neighborhood of $f(x)$ in T so $f^{-1}(V)$ is a neighborhood of x in (S, \mathcal{S}) . Hence $f^{-1}(V) \cap A = f_A^{-1}(V)$ is a neighborhood of x in (A, \mathcal{A}) . Since f_A is continuous (relative to (A, \mathcal{A})) at each $x \in A$, f_A is continuous from the previous result.

For a simple counterexample, suppose that f is not continuous at a particular $x \in S$. The set $\{x\}$ has the trivial relative topology $\{\emptyset, \{x\}\}$ and so f restricted to $\{x\}$ is trivially continuous.

Product Spaces

Cartesian product sets are ubiquitous in mathematics, so a natural question is this: given topological spaces (S, \mathcal{S}) and (T, \mathcal{T}) , what is a natural topology for $S \times T$? The answer is very simple using the concept of a [base](#) above.

Suppose that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces. The collection $\mathcal{B} = \{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\}$ is a base for a topology on $S \times T$, called the *product topology* associated with the given spaces.

Proof

Trivially, $S \times T = \bigcup \mathcal{B}$. In fact $S \times T \in \mathcal{B}$. Next if $A \times B \in \mathcal{B}$ and $C \times D \in \mathcal{B}$, so that A, C are open in S and B, D are open in T , then

$$(A \times B) \cap (C \times D) = (A \cap C) \times (B \cap D) \in \mathcal{B} \quad (1.9.7)$$

Hence \mathcal{B} is a base for a topology on $S \times T$.

So basically, we want the product of open sets to be open in the product space. The product topology is the smallest topology that makes this happen. The definition above can be extended to very general product spaces, but to state the extension, let's recall how general product sets are constructed. Suppose that S_i is a set for each i in a nonempty index set I . Then the product set $\prod_{i \in I} S_i$ is the set of all functions $x : I \rightarrow \bigcup_{i \in I} S_i$ such that $x(i) \in S_i$ for $i \in I$.

Suppose that (S_i, \mathcal{S}_i) is a topological space for each i in a nonempty index set I . Then

$$\mathcal{B} = \left\{ \prod_{i \in I} A_i : A_i \in \mathcal{S}_i \text{ for all } i \in I \text{ and } A_i = S_i \text{ for all but finitely many } i \in I \right\} \quad (1.9.8)$$

is a base for a topology on $\prod_{i \in I} S_i$, known as the *product topology* associated with the given spaces.

Proof

The proof is just as before, except for the more complicated notation. Trivially $\prod_{i \in I} S_i = \bigcup \mathcal{B}$, and \mathcal{B} is closed under finite intersections.

Suppose again that S_i is a set for each i in a nonempty index set I . For $j \in I$, recall that *projection function* $p_j : \prod_{i \in I} S_i \rightarrow S_j$ is defined by $p_j(x) = x(j)$.

Suppose again that (S_i, \mathcal{S}_i) is a topological space for each $i \in I$, and give the product space $\prod_{i \in I} S_i$ the product topology. The projection function p_j is continuous for each $j \in I$.

Proof

If U is open in S_j then $p_j^{-1}(U) = \prod_{i \in I} A_i$ where $A_i = S_i$ for $i \in I$ with $i \neq j$, and $A_j = U$, so clearly this inverse image is open in the product space.

As a special case of all this, suppose that (S, \mathcal{S}) is a topological space, and that $S_i = S$ for all $i \in I$. Then the product space $\prod_{i \in I} S_i$ is the set of all functions from I to S , sometimes denoted S^I . In this case, the base for the product topology on S^I is

$$\mathcal{B} = \left\{ \prod_{i \in I} A_i : A_i \in \mathcal{S} \text{ for all } i \in I \text{ and } A_i = S \text{ for all but finitely many } i \in I \right\} \quad (1.9.9)$$

For $j \in I$, the projection function p_j just returns the value of a function $x : I \rightarrow S$ at j : $p_j(x) = x(j)$. This projection function is continuous. Note in particular that no topology is necessary on the domain I .

Examples and Special Cases

The Trivial Topology

Suppose that S is a nonempty set. Then $\{S, \emptyset\}$ is a topology on S , known as the *trivial topology*.

With the trivial topology, no two distinct points can be separated. So the topology cannot distinguish between points, in a sense, and all points in S are close to each other. Clearly, this topology is not very interesting, except as a place to start. Since there is only one nonempty open set (S itself), the space is connected, and every subset of S is compact. A sequence in S converges to every point in S .

Suppose that S has the trivial topology and that (T, \mathcal{T}) is another topological space.

1. Every function from T to S is continuous.
2. If (T, \mathcal{T}) is a Hausdorff space then the only continuous functions from S to T are constant functions.

Proof

1. Suppose $f : T \rightarrow S$. Then $f^{-1}(S) = T \in \mathcal{T}$ and $f^{-1}(\emptyset) = \emptyset \in \mathcal{T}$, so f is continuous.
2. Suppose that $f : S \rightarrow T$ is continuous and that u, v are distinct elements in the range of f . There exist disjoint open sets $U, V \in \mathcal{T}$ with $u \in U$ and $v \in V$. But $f^{-1}(U)$ and $f^{-1}(V)$ are nonempty and so must be S . If $x \in S$, $f(x) \in U$ and $f(x) \in V$, a contradiction.

The Discrete Topology

At the opposite extreme from the trivial topology, with the smallest collection of open sets, is the discrete topology, with the largest collection of open sets.

Suppose that S is a nonempty set. The power set $\mathcal{P}(S)$ (consisting of all subsets of S) is a topology, known as the *discrete topology*.

So in the discrete topology, every set is both open and closed. All points are separated, and in a sense, widely so. No point is close to another point. With the discrete topology, S is Hausdorff, disconnected, and the compact subsets are the finite subsets. A sequence in S converges to $x \in S$, if and only if all but finitely many terms of the sequence are x .

Suppose that S has the discrete topology and that (T, \mathcal{T}) is another topological space.

1. Every function from S to T is continuous.
2. If (T, \mathcal{T}) is connected, then the only continuous functions from T to S are constant functions.

Proof

1. Trivially, if $f : S \rightarrow T$, then $f^{-1}(U) \in \mathcal{P}(S)$ for $U \in \mathcal{T}$ so f is continuous.
2. Suppose that $f : T \rightarrow S$ is continuous and that x is in the range of f . Then $\{x\}$ is open and closed in S , so $f^{-1}\{x\}$ is open and closed in T . If T is connected, this means that $f^{-1}\{x\} = T$.

Euclidean Spaces

The standard topologies used in the Euclidean spaces are the topologies built from open sets that you familiar with.

For the set of real numbers \mathbb{R} , let $\mathcal{B} = \{(a, b) : a, b \in \mathbb{R}, a < b\}$, the collection of open intervals. Then \mathcal{B} is a base for a topology \mathcal{R} on \mathbb{R} , known as the *Euclidean topology*.

Proof

Clearly the conditions for \mathcal{B} to be a base given above are satisfied. First $\mathbb{R} = \bigcup \mathcal{B}$. Next, if $(a, b) \in \mathcal{B}$ and $(c, d) \in \mathcal{B}$ and $x \in (a, b) \cap (c, d)$, then $x \in (\max\{a, c\}, \min\{b, d\}) \subseteq (a, b) \cap (c, d)$.

The space $(\mathbb{R}, \mathcal{R})$ satisfies many properties that are motivations for definitions in topology in the first place. The convergence of a sequence in \mathbb{R} , in the topological sense given above, is the same as the definition of convergence in calculus. The same statement holds for the continuity of a function f from \mathbb{R} to \mathbb{R} .

Before listing other topological properties, we give a characterization of compact sets, known as the *Heine-Borel theorem*, named for Eduard Heine and Émile Borel. Recall that $A \subseteq \mathbb{R}$ is *bounded* if $A \subseteq [a, b]$ for some $a, b \in \mathbb{R}$ with $a < b$.

A subset $C \subseteq \mathbb{R}$ is compact if and only if C is closed and bounded.

So in particular, closed, bounded intervals of the form $[a, b]$ with $a, b \in \mathbb{R}$ and $a < b$ are compact.

The space $(\mathbb{R}, \mathcal{R})$ has the following properties:

1. Hausdorff.
2. Connected.
3. Locally compact.
4. Second countable.

Proof

1. Distinct points in \mathbb{R} can be separated by open intervals.
2. \mathbb{R} has no proper subset that is both open and closed.
3. If A is a neighborhood of $x \in \mathbb{R}$, then there exists $a, b \in \mathbb{R}$ with $a < b$ such that $x \in [a, b] \subseteq A$. The closed interval $[a, b]$ is compact.
4. The collection $\mathcal{Q} = \{(a, b) : a, b \in \mathbb{Q}, a < b\}$ is a countable base for \mathcal{R} , where as usual, \mathbb{Q} is the set of rational real numbers.

As noted in the proof, \mathbb{Q} , the set of rationals, is countable and is dense in \mathbb{R} . Another countable, dense subset is $\mathbb{D} = \{j/2^n : n \in \mathbb{N} \text{ and } j \in \mathbb{Z}\}$, the set of dyadic rationals (or *binary rationals*). For the higher-dimensional Euclidean spaces, we can use the product topology based on the topology of the real numbers.

For $n \in \{2, 3, \dots\}$, let $(\mathbb{R}^n, \mathcal{R}_n)$ be the n -fold product space corresponding to the space $(\mathbb{R}, \mathcal{R})$. Then \mathcal{R}_n is the *Euclidean topology* on \mathbb{R}^n .

A subset $A \subseteq \mathbb{R}^n$ is *bounded* if there exists $a, b \in \mathbb{R}$ with $a < b$ such that $A \subseteq [a, b]^n$, so that A fits inside of an n -dimensional “block”.

A subset $C \subseteq \mathbb{R}^n$ is compact if and only if C is closed and bounded.

The space $(\mathbb{R}^n, \mathcal{R}_n)$ has the following properties:

1. Hausdorff.
2. Connected.
3. Locally compact.
4. Second countable.

1.10: Metric Spaces

Basic Theory

Most of the important topological spaces that occur in applications (like probability) have an additional structure that gives a *distance* between points in the space.

Definitions

A *metric space* consists of a nonempty set S and a function $d : S \times S \rightarrow [0, \infty)$ that satisfies the following axioms: For $x, y, z \in S$,

1. $d(x, y) = 0$ if and only if $x = y$.
2. $d(x, y) = d(y, x)$.
3. $d(x, z) \leq d(x, y) + d(y, z)$.

The function d is known as a *metric* or a *distance function*.

So as the name suggests, $d(x, y)$ is the *distance* between points $x, y \in S$. The axioms are intended to capture the essential properties of distance from geometry. Part (a) is the *positive property*; the distance is strictly positive if and only if the points are distinct. Part (b) is the *symmetric property*; the distance from x to y is the same as the distance from y to x . Part (c) is the *triangle inequality*; going from x to z cannot be longer than going from x to z by way of a third point y .

Note that if (S, d) is a metric space, and A is a nonempty subset of S , then the set A with d restricted to $A \times A$ is also a metric space (known as a *subspace*). The next definitions also come naturally from geometry:

Suppose that (S, d) is a metric space, and that $x \in S$ and $r \in (0, \infty)$.

1. $B(x, r) = \{y \in S : d(x, y) < r\}$ is the *open ball* with center x and radius r .
2. $C(x, r) = \{y \in S : d(x, y) \leq r\}$ is the *closed ball* with center x and radius r .

A metric on a space induces a topology on the space in a natural way.

Suppose that (S, d) is a metric space. By definition, a set $U \subseteq S$ is *open* if for every $x \in U$ there exists $r \in (0, \infty)$ such that $B(x, r) \subseteq U$. The collection \mathcal{S}_d of open subsets of S is a topology.

Proof

1. Trivially S is open and vacuously \emptyset is open.
2. Suppose that A_i is open for i in an arbitrary index set I , and let $A = \bigcup_{i \in I} A_i$. If $x \in A$ then $x \in A_i$ for some $i \in I$. Since A_i is open, there exists $r \in (0, \infty)$ with $B(x, r) \subseteq A_i$. But then $B(x, r) \subseteq A$ so A is open.
3. Suppose that A_i is open for i in a finite index set I , and let $A = \bigcap_{i \in I} A_i$. If $x \in A$ then $x \in A_i$ for every $i \in I$. Hence for each $i \in I$ there exist $r_i \in (0, \infty)$ such that $B(x, r_i) \subseteq A_i$. Let $r = \min\{r_i : i \in I\}$. Since I is finite, $r > 0$ and $B(x, r) \subseteq B(x, r_i) \subseteq A_i$ for each $i \in I$. Hence $B(x, r) \subseteq A$, so A is open.

As the names suggests, an open ball is in fact *open* and a closed ball is in fact *closed*.

Suppose again that (S, d) is a metric space, and that $x \in S$ and $r \in (0, \infty)$. Then

1. $B(x, r)$ is open.
2. $C(x, r)$ is closed.

Proof

1. Let $y \in B(x, r)$, and let $a = d(x, y)$, so that $a < r$. If $z \in B(y, r - a)$ then we have $d(x, y) = a$ and $d(y, z) < r - a$, so by the triangle inequality, $d(x, z) < a + (r - a) = r$. Hence $z \in B(x, r)$. Thus $B(y, r - a) \subseteq B(x, r)$. It follows that $B(x, r)$ is open.
2. We show that $U = [C(x, r)]^c$ is open. Suppose that $y \in U$, and let $a = d(x, y)$, so that $a > r$. Let $z \in B(y, a - r)$ and suppose that $z \in C(x, r)$, so that $d(z, x) \leq r$. By the triangle inequality again,

$$d(x, y) \leq d(x, z) + d(z, y) < r + (a - r) = a \quad (1.10.1)$$

a contradiction. Hence $z \in U$. So $B(y, a - r) \subseteq U$.

Recall that for a general topological space, a *neighborhood* of a point $x \in S$ is a set $A \subseteq S$ with the property that there exists an open set U with $x \in U \subseteq A$. It follows that in a metric space, $A \subseteq S$ is a neighborhood of x if and only if there exists $r > 0$ such that $B(x, r) \subseteq A$. In words, a neighborhood of a point must contain an open ball about that point.

It's easy to construct new metrics from ones that we already have. Here's one such result.

Suppose that S is a nonempty set, and that d, e are metrics on S , and $c \in (0, \infty)$. Then the following are also metrics on S :

1. cd
2. $d + e$

Proof

1. Recall that cd is the function defined by $(cd)(x, y) = cd(x, y)$ for $(x, y) \in S^2$. Since $c > 0$, it's easy to see that the axioms are satisfied.
2. Recall that $d + e$ is the function defined by $(d + e)(x, y) = d(x, y) + e(x, y)$ for $(x, y) \in S^2$. Again, it's easy to see that the axioms are satisfied.

Since a metric space produces a topological space, all of the definitions for general topological spaces apply to metric spaces as well. In particular, in a metric space, distinct points can always be separated.

A metric space (S, d) is a Hausdorff space.

Proof

Let x, y be distinct points in S . Then $r = d(x, y) > 0$. The sets $B(x, r/2)$ and $B(y, r/2)$ are open, and contain x and y , respectively. Suppose that $z \in B(x, r/2) \cap B(y, r/2)$. By the triangle inequality,

$$d(x, y) \leq d(x, z) + d(z, y) < \frac{r}{2} + \frac{r}{2} = r \quad (1.10.2)$$

a contradiction. Hence $B(x, r/2)$ and $B(y, r/2)$ are disjoint.

Metrizable Spaces

Again, every metric space is a topological space, but not conversely. A non-Hausdorff space, for example, cannot correspond to a metric space. We know there are such spaces; a set S with more than one point, and with the trivial topology $\mathcal{S} = \{S, \emptyset\}$ is non-Hausdorff.

Suppose that (S, \mathcal{S}) is a topological space. If there exists a metric d on S such that $\mathcal{S} = \mathcal{S}_d$, then (S, \mathcal{S}) is said to be *metrizable*.

It's easy to see that different metrics can induce the same topology. For example, if d is a metric and $c \in (0, \infty)$, then the metrics d and cd induce the same topology.

Let S be a nonempty set. Metrics d and e on S are *equivalent*, and we write $d \equiv e$, if $\mathcal{S}_d = \mathcal{S}_e$. The relation \equiv is an equivalence relation on the collection of metrics on S . That is, for metrics d, e, f on S ,

1. $d \equiv d$, the *reflexive property*.
2. If $d \equiv e$ then $e \equiv d$, the *symmetric property*.
3. If $d \equiv e$ and $e \equiv f$ then $d \equiv f$, the *transitive property*.

There is a simple condition that characterizes when the topology of one metric is finer than the topology of another metric, and then this in turn leads to a condition for equivalence of metrics.

Suppose again that S is a nonempty set and that d, e are metrics on S . Then \mathcal{S}_e is finer than \mathcal{S}_d if and only if every open ball relative to d contains an open ball relative to e .

Proof

Suppose that $\mathcal{S}_d \subseteq \mathcal{S}_e$ so that \mathcal{S}_e is finer than \mathcal{S}_d . If $x \in S$ and $a \in (0, \infty)$, then the open ball $B_d(x, a)$ centered at x of radius a for the metric d is in \mathcal{S}_d and hence in \mathcal{S}_e . Thus there exists $b \in (0, \infty)$ such that $B_e(x, b) \subseteq B_d(x, a)$. Conversely, suppose that the condition in the theorem holds and suppose that $U \in \mathcal{S}_d$. If $x \in U$ there exists $a \in (0, \infty)$ such that $B_d(x, a) \subseteq U$. Hence there exists $b \in (0, \infty)$ such that $B_e(x, b) \subseteq B_d(x, a) \subseteq U$. So $U \in \mathcal{S}_e$.

It follows that metrics d and e on S are equivalent if and only if every open ball relative to one of the metrics contains an open ball relative to the other metric.

So every metrizable topology on S corresponds to an equivalence class of metrics that produce that topology. Sometimes we want to know that a topological space is metrizable, because of the nice properties that it will have, but we don't really need to use a specific metric that generates the topology. At any rate, it's important to have conditions that are sufficient for a topological space to be metrizable. The most famous such result is the *Urysohn metrization theorem*, named for the Russian mathematician Pavel Uryshon:

Suppose that (S, \mathcal{S}) is a regular, second-countable, Hausdorff space. Then (S, \mathcal{S}) is metrizable.

Review of the terms

Recall that *regular* means that every closed set and point not in the set can be separated by disjoint open sets. As discussed earlier, *Hausdorff* means that any two distinct points can be separated by disjoint open sets. Finally, *second-countable* means that there is a countable base for the topology, that is, there is a countable collection of open sets with the property that every other open set is a union of sets in the collection.

Convergence

With a distance function, the convergence of a sequence can be characterized in a manner that is just like calculus. Recall that for a general topological space (S, \mathcal{S}) , if $(x_n : n \in \mathbb{N}_+)$ is a sequence of points in S and $x \in S$, then $x_n \rightarrow x$ as $n \rightarrow \infty$ means that for every neighborhood U of x , there exists $m \in \mathbb{N}_+$ such that $x_n \in U$ for $n > m$.

Suppose that (S, d) is a metric space, and that $(x_n : n \in \mathbb{N}_+)$ is a sequence of points in S and $x \in S$. Then $x_n \rightarrow x$ as $n \rightarrow \infty$ if and only if for every $\epsilon > 0$ there exists $m \in \mathbb{N}_+$ such that if $n > m$ then $d(x_n, x) < \epsilon$. Equivalently, $x_n \rightarrow x$ as $n \rightarrow \infty$ if and only if $d(x_n, x) \rightarrow 0$ as $n \rightarrow \infty$ (in the usual calculus sense).

Proof

Suppose that $x_n \rightarrow x$ as $n \rightarrow \infty$, and let $\epsilon > 0$. Then $B(x, \epsilon)$ is a neighborhood of x , so there exists $m \in \mathbb{N}_+$ such that $x_n \in B(x, \epsilon)$ for $n > m$, which is the condition in the theorem. Conversely, suppose that condition in the theorem holds, and let U be a neighborhood of x . Then there exists $\epsilon > 0$ such that $B(x, \epsilon) \subseteq U$. By assumption, there exists $m \in \mathbb{N}_+$ such that if $n > m$ then $x_n \in B(x, \epsilon) \subseteq U$.

So, no matter how tiny $\epsilon > 0$ may be, all but finitely many terms of the sequence are within ϵ distance of x . As one might hope, limits are unique.

Suppose again that (S, d) is a metric space. Suppose also that $(x_n : n \in \mathbb{N}_+)$ is a sequence of points in S and that $x, y \in S$. If $x_n \rightarrow x$ as $n \rightarrow \infty$ and $x_n \rightarrow y$ as $n \rightarrow \infty$ then $x = y$.

Proof

This follows immediately since a metric space is a Hausdorff space, and the limit of a sequence in a Hausdorff space is unique. Here's a direct proof: Let $\epsilon > 0$. Then there exists $k \in \mathbb{N}_+$ such that $d(x_n, x) < \epsilon/2$ for $n > k$, and there exists $m \in \mathbb{N}_+$ such that $d(x_n, y) < \epsilon/2$ for $n > m$. Let $n > \max\{k, m\}$. By the triangle inequality,

$$d(x, y) \leq d(x, x_n) + d(x_n, y) < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \quad (1.10.3)$$

So we have $d(x, y) < \epsilon$ for every $\epsilon > 0$ and hence $d(x, y) = 0$ and thus $x = y$.

Convergence of a sequence is a topological property, and so is preserved under equivalence of metrics.

Suppose that d, e are equivalent metrics on S , and that $(x_n : n \in \mathbb{N}_+)$ is a sequence of points in S and $x \in S$. Then $x_n \rightarrow x$ as $n \rightarrow \infty$ relative to d if and only if $x_n \rightarrow x$ as $n \rightarrow \infty$ relative to e .

Closed subsets of a metric space have a simple characterization in terms of convergent sequences, and this characterization is more intuitive than the abstract axioms in a general topological space.

Suppose again that (S, d) is a metric space. Then $A \subseteq S$ is closed if and only if whenever a sequence of points in A converges, the limit is also in A .

Proof

Suppose that A is closed and that $(x_n : n \in \mathbb{N}_+)$ is a sequence of points in A with $x_n \rightarrow x \in S$ as $n \rightarrow \infty$. Suppose that $x \in A^c$. Since A^c is open, $x_n \in A^c$ for n sufficiently large, a contradiction. Hence $x \in A$. Conversely, suppose that A has the sequential closure property, but that A is not closed. Then A^c is not open. This means that there exists $x \in A^c$ with the property that every neighborhood of x has points in A . Specifically, for each $n \in \mathbb{N}_+$ there exists $x_n \in B(x, 1/n)$ with $x_n \in A$. But clearly $x_n \rightarrow x$ as $n \rightarrow \infty$, again a contradiction.

The following definition also shows up in standard calculus. The idea is to have a criterion for convergence of a sequence that does not require knowing *a-priori* the limit. But for metric spaces, this definition takes on added importance.

Suppose again that (S, d) is a metric space. A sequence of points $(x_n : n \in \mathbb{N}_+)$ in S is a *Cauchy sequence* if for every $\epsilon > 0$ there exist $k \in \mathbb{N}_+$ such that if $m, n \in \mathbb{N}_+$ with $m > k$ and $n > k$ then $d(x_m, x_n) < \epsilon$.

Cauchy sequences are named for the ubiquitous Augustin Cauchy. So for a Cauchy sequence, no matter how tiny $\epsilon > 0$ may be, all but finitely many terms of the sequence will be within ϵ distance of each other. A convergent sequence is always Cauchy.

Suppose again that (S, d) is a metric space. If a sequence of points $(x_n : n \in \mathbb{N}_+)$ in S converges, then the sequence is Cauchy.

Proof

By assumption, there exists $x \in S$ such that $x_n \rightarrow x$ as $n \rightarrow \infty$. Let $\epsilon > 0$. There exists $k \in \mathbb{N}_+$ such that if $n \in \mathbb{N}_+$ and $n > k$ then $d(x_n, x) < \epsilon/2$. Hence if $m, n \in \mathbb{N}_+$ with $m > k$ and $n > k$ then by the triangle inequality,

$$d(x_m, x_n) \leq d(x_m, x) + d(x, x_n) < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \quad (1.10.4)$$

So the sequence is Cauchy.

Conversely, one might think that a Cauchy sequence should converge, but it's relatively trivial to create a situation where this is false. Suppose that (S, d) is a metric space, and that there is a point $x \in S$ that is the limit of a sequence of points in S that are all distinct from x . Then the space $T = S - \{x\}$ with the metric d restricted to $T \times T$ has a Cauchy sequence that does not converge. Essentially, we have created a “convergence hole”. So our next definition is very natural and very important.

Suppose again that (S, d) is metric space and that $A \subseteq S$. Then A is *complete* if every Cauchy sequence in A converges to a point in A .

Of course, completeness can be applied to the entire space S . Trivially, a complete set must be closed.

Suppose again that (S, d) is a metric space, and that $A \subseteq S$. If A is complete, then A is closed.

Proof

Suppose that $\mathbf{x} = (x_n : n \in \mathbb{N})$ is a sequence of points in A and that $x_n \rightarrow x \in S$ as $n \rightarrow \infty$. Then \mathbf{x} is a Cauchy sequence, and so by completeness, $x \in A$. Hence A is closed by (12).

Completeness is such a crucial property that it is often imposed as an assumption on metric spaces that occur in applications. Even though a Cauchy sequence may not converge, here is a partial result that will be useful later: if a Cauchy sequence has a convergent subsequence, then the sequence itself converges.

Suppose again the (S, d) is a metric space, and that $(x_n : n \in \mathbb{N}_+)$ is a Cauchy sequence in S . If there exists a subsequence $(x_{n_k} : k \in \mathbb{N}_+)$ such that $x_{n_k} \rightarrow x \in S$ as $k \rightarrow \infty$, then $x_n \rightarrow x$ as $n \rightarrow \infty$.

Proof

Recall that in the construction of a subsequence, the indices $(n_k : k \in \mathbb{N}_+)$ must be a strictly increasing sequence in \mathbb{N}_+ . In particular, $n_k \rightarrow \infty$ as $k \rightarrow \infty$. So let $\epsilon > 0$. From the hypotheses, there exists $j \in \mathbb{N}_+$ such that if $k > j$ then $d(x_{n_k}, x) < \epsilon/2$. There exists $N \in \mathbb{N}_+$ such that if $m > N$ and $p > N$ then $d(x_m, x_p) < \epsilon/2$. Now let $m > N$. Pick $k \in \mathbb{N}_+$ such that $k > j$ and $n_k > N$. By the triangle inequality,

$$d(x_m, x) \leq d(x_m, x_{n_k}) + d(x_{n_k}, x) \leq \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon \quad (1.10.5)$$

Continuity

In metric spaces, continuity of functions also has simple characterizations in terms of that are familiar from calculus. We start with local continuity. Recall that the general topological definition is that $f : S \rightarrow T$ is continuous at $x \in S$ if $f^{-1}(V)$ is a neighborhood of x in S for every open set V of $f(x)$ in T .

Suppose that (S, d) and (T, e) are metric spaces, and that $f : S \rightarrow T$. The continuity of f at $x \in S$ is equivalent to each of the following conditions:

1. If $(x_n : n \in \mathbb{N}_+)$ is a sequence in S with $x_n \rightarrow x$ as $n \rightarrow \infty$ then $f(x_n) \rightarrow f(x)$ as $n \rightarrow \infty$.
2. For every $\epsilon > 0$, there exists $\delta > 0$ such that if $y \in S$ and $d(x, y) < \delta$ then $e[f(y) - f(x)] < \epsilon$.

Proof

1. This condition is *sequential continuity* at x . Continuity at x implies sequential continuity at x for general topological spaces, and hence for metric spaces. Conversely, suppose that sequential continuity holds at $x \in S$, and let V be a neighborhood of $f(x)$ in T . If $U = f^{-1}(V)$ is not a neighborhood of x in S , then for every $n \in \mathbb{N}_+$, there exists $x_n \in B(x, 1/n)$ with $x_n \notin U$. But then clearly $x_n \rightarrow x$ as $n \rightarrow \infty$ but $f(x_n)$ does not converge to $f(x)$ as $n \rightarrow \infty$, a contradiction.
2. Suppose that f is continuous at x . For $\epsilon > 0$, $B_T[f(x), \epsilon]$ is a neighborhood of $f(x)$, and hence $U = f^{-1}(B_T[f(x), \epsilon])$ is a neighborhood of x . Hence there exists $\delta > 0$ such that $B_S(x, \delta) \subseteq U$. But this means that if $d(y, x) < \delta$ then $e[f(y), f(x)] < \epsilon$. Conversely suppose that the condition in (b) holds, and suppose that V is a neighborhood of $f(x)$. Then there exists $\epsilon > 0$ such that $B_T[f(x), \epsilon] \subseteq V$. By assumption, there exists $\delta > 0$ such that if $y \in B_S(x, \delta)$ then $f(y) \in B_T[f(x), \epsilon] \subseteq V$. This means that $f^{-1}(V)$ is a neighborhood of x .

More generally, recall that f continuous on $A \subseteq S$ means that f is continuous at each $x \in A$, and that f continuous means that f is continuous on S . So general continuity can be characterized in terms of sequential continuity and the ϵ - δ condition.

On a metric space, there are stronger versions of continuity.

Suppose again that (S, d) and (T, e) are metric spaces and that $f : S \rightarrow T$. Then f is *uniformly continuous* if for every $\epsilon > 0$ there exists $\delta > 0$ such that if $x, y \in S$ with $d(x, y) < \delta$ then $e[f(x), f(y)] < \epsilon$.

In the ϵ - δ formulation of ordinary point-wise continuity above, δ depends on the point x in addition to ϵ . With uniform continuity, there exists a δ depending only on ϵ that works *uniformly* in $x \in S$.

Suppose again that (S, d) and (T, e) are metric spaces, and that $f : S \rightarrow T$. If f is uniformly continuous then f is continuous.

Here is an even stronger version of continuity.

Suppose again that (S, d) and (T, e) are metric spaces, and that $f : S \rightarrow T$. Then f is *Hölder continuous* with exponent $\alpha \in (0, \infty)$ if there exists $C \in (0, \infty)$ such that $e[f(x), f(y)] \leq C[d(x, y)]^\alpha$ for all $x, y \in S$.

The definition is named for Otto Höder. The exponent α is more important than the constant C , which generally does not have a name. If $\alpha = 1$, f is said to be *Lipschitz continuous*, named for the German mathematician Rudolf Lipschitz.

Suppose again that (S, d) and (T, e) are metric spaces, and that $f : S \rightarrow T$. If f is Hölder continuous with exponent $\alpha > 0$ then f is uniformly continuous.

The case where $\alpha = 1$ and $C < 1$ is particularly important.

Suppose again that (S, d) and (T, e) are metric spaces. A function $f : S \rightarrow T$ is a *contraction* if there exists $C \in (0, 1)$ such that

$$e[f(x), f(y)] \leq Cd(x, y), \quad x, y \in S \quad (1.10.6)$$

So contractions shrink distance. By the result above, a contraction is uniformly continuous. Part of the importance of contraction maps is due to the famous *Banach fixed-point theorem*, named for Stefan Banach.

Suppose that (S, d) is a complete metric space and that $f : S \rightarrow S$ is a contraction. Then f has a unique *fixed point*. That is, there exists exactly one $x^* \in S$ with $f(x^*) = x^*$. Let $x_0 \in S$, and recursively define $x_n = f(x_{n-1})$ for $n \in \mathbb{N}_+$. Then $x_n \rightarrow x^*$ as $n \rightarrow \infty$.

Functions that preserve distance are particularly important. The term *isometry* means distance-preserving.

Suppose again that (S, d) and (T, e) are metric spaces, and that $f : S \rightarrow T$. Then f is an *isometry* if $e[f(x), f(y)] = d(x, y)$ for every $x, y \in S$.

Suppose again that (S, d) and (T, e) are metric spaces, and that $f : S \rightarrow T$. If f is an isometry, then f is one-to-one and Lipschitz continuous.

Proof

If $x, y \in S$ with $x \neq y$, then $e[f(x), f(y)] = d(x, y) > 0$, so $f(x) \neq f(y)$. Hence f is one-to-one. Directly from the definition, f is Hölder continuous with exponent $\alpha = 1$ and constant multiple $C = 1$.

In particular, an isometry f is uniformly continuous. If one metric space can be mapped isometrically *onto* another metric space, the spaces are essentially the same.

Metric spaces (S, d) and (T, e) are *isometric* if there exists an isometry f that maps S onto T . Isometry is an equivalence relation on metric spaces. That is, for metric spaces (S, d) , (T, e) , and (U, ρ) ,

1. (S, d) is isometric to (S, d) , the *reflexive property*.
2. If (S, d) is isometric to (T, e) then (T, e) is isometric to (S, d) , the *symmetric property*.
3. If (S, d) is isometric to (T, e) and (T, e) is isometric to (U, ρ) , then (S, d) is isometric to (U, ρ) , the *transitive property*.

Proof

1. The identity function $I : S \rightarrow S$ defined by $I(x) = x$ for $x \in S$ is an isometry from (S, d) onto (S, d) .
2. If f is an isometry from (S, d) onto (T, e) then f^{-1} is an isometry from (T, e) onto (S, d) .
3. If f is an isometry from (S, d) onto (T, e) and g is an isometry from (T, e) onto (U, ρ) , then $g \circ f$ is an isometry from (S, d) to (U, ρ) .

In particular, if metric spaces (S, d) and (T, e) are isometric, then as topological spaces, they are homeomorphic.

Compactness and Boundedness

In a metric space, various definitions related to a set being *bounded* are natural, and are related to the general concept of compactness.

Suppose again that (S, d) is a metric space, and that $A \subseteq S$. Then A is *bounded* if there exists $r \in (0, \infty)$ such that $d(x, y) \leq r$ for all $x, y \in A$. The *diameter* of A is

$$\text{diam}(A) = \inf\{r > 0 : d(x, y) < r \text{ for all } x, y \in A\} \quad (1.10.7)$$

Additional details

Recall that $\inf(\emptyset) = \infty$, so $\text{diam}(A) = \infty$ if A is unbounded. In the bounded case, note that if the distance between points in A is bounded by $r \in (0, \infty)$, then the distance is bounded by any $s \in [r, \infty)$. Hence the diameter definition makes sense.

So A is bounded if and only if $\text{diam}(A) < \infty$. Diameter is an increasing function relative to the subset partial order.

Suppose again that (S, d) is a metric space, and that $A \subseteq B \subseteq S$. Then $\text{diam}(A) \leq \text{diam}(B)$.

Our next definition is stronger, but first let's review some terminology that we used for general topological spaces: If S is a set, A a subset of S , and \mathcal{A} a collection of subsets of S , then \mathcal{A} is said to *cover* A if $A \subseteq \bigcup \mathcal{A}$. So with this terminology, we can talk about open covers, closed covers, finite covers, disjoint covers, and so on.

Suppose again that (S, d) is a metric space, and that $A \subseteq S$. Then A is *totally bounded* if for every $r > 0$ there is a finite cover of A with open balls of radius r .

Recall that for a general topological space, a set A is *compact* if every open cover of A has a finite subcover. So in a metric space, the term *precompact* is sometimes used instead of *totally bounded*: The set A is totally bounded if every cover of A with open balls of radius r has a finite subcover.

Suppose again that (S, d) is a metric space. If $A \subseteq S$ is totally bounded then A is bounded.

Proof

There exists a finite cover of A with open balls of radius 1. Let C denote the set of centers of the balls, and let $c = \max\{d(u, v) : u, v \in C\}$, the maximum distance between two centers. Since C is finite, $c < \infty$. Now let $x, y \in A$. Since the balls cover A , there exist $u, v \in C$ with $x \in B(u, 1)$ and $y \in B(v, 1)$. By the triangle inequality (what else?)

$$d(x, y) \leq d(x, u) + d(u, v) + d(v, y) \leq 2 + c \quad (1.10.8)$$

Hence A is bounded.

Since a metric space is a Hausdorff space, a compact subset of a metric space is closed. Compactness also has a simple characterization in terms of convergence of sequences.

Suppose again that (S, d) is a metric space. A subset $C \subseteq S$ is compact if and only if every sequence of points in C has a subsequence that converges to a point in C .

Proof

The condition in the theorem is known as *sequential compactness*, so we want to show that sequential compactness is equivalent to compactness. The proof is harder than most of the others in this section, but the proof presented here is the nicest I have found, and is due to Anton Schep.

Suppose that C is compact and that $\mathbf{x} = (x_n : n \in \mathbb{N}_+)$ is a sequence of points in C . Let $A = \{x_n : n \in \mathbb{N}_+\} \subseteq C$, the unordered set of distinct points in the sequence. If A is finite, then some element of $a \in A$ must occur infinitely many times in the sequence. In this case, we can construct a subsequence of \mathbf{x} all of whose terms are a , and so this subsequence trivially converges to $a \in C$. Suppose next that A is infinite. Since the space is Hausdorff, C is closed, and therefore $\text{cl}(A) \subseteq C$. Our next claim is that there exists $a \in \text{cl}(A)$ such that for every $r > 0$, the set $A \cap B(a, r)$ is infinite. If the claim is false, then for each $a \in \text{cl}(A)$ there exists $r_a > 0$ such that $A \cap B(a, r_a)$ is finite. It then follows that for each $a \in A$, there exists $\epsilon_a > 0$ such that $A \cap B(a, \epsilon_a) = \{a\}$. But then $\mathcal{U} = \{B(a, \epsilon_a) : a \in \text{cl}(A)\} \cup \{\text{cl}(A)^c\}$ is an open cover of C that has no finite subcover, a contradiction. So the claim is true and for some $a \in \text{cl}(A)$, the set $A \cap B(a, r)$ is infinite for each $r > 0$. We can construct a subsequence of \mathbf{x} that converges to $a \in C$.

Conversely, suppose that C is sequentially compact. If $\mathbf{x} = (x_n : n \in \mathbb{N}_+)$ is a Cauchy sequence in C , then by assumption, \mathbf{x} has a subsequence that converges to some $x \in C$. But then by (17) the sequence \mathbf{x} itself converges to x , so it follows that C is complete. We next show that C is totally bounded. Our goal is to show that C can be covered by a finite number of balls of an arbitrary radius $r > 0$. Pick $x_1 \in C$. If $C \subseteq B(x_1, r)$ then we are done. Otherwise, pick $x_2 \in C \setminus B(x_1, r)$. If $C \subseteq B(x_1, r) \cup B(x_2, r)$ then again we are done. Otherwise there exists $x_3 \in C \setminus [B(x_1, r) \cup B(x_2, r)]$. This process must terminate in a finite number of steps or otherwise we would have a sequence of points $(x_n : n \in \mathbb{N}_+)$ in C with the property that $d(x_n, x_m) \geq r$ for every $n, m \in \mathbb{N}_+$. Such a sequence does not have a convergent subsequence. Suppose now that \mathcal{U} is an open cover of C and let $c = \text{diam}(C)$. Then C can be covered by a finite number of closed balls of with centers in C and with radius $c/4$. It follows that at least one of these balls cannot be covered by a finite subcover from \mathcal{U} . Let C_1 denote the intersection of this ball with C . Then C_1 is closed and is sequentially compact with $\text{diam}(C_1) \leq c/4$. Repeating the argument, we generate a nested sequence of close sets (C_1, C_2, \dots) such that $\text{diam}(C_n) \leq c/2^n$, and with the property that C_n cannot be finitely covered by \mathcal{U} for each $n \in \mathbb{N}_+$. Pick $x_n \in C_n$ for each $n \in \mathbb{N}_+$. Then $\mathbf{x} = (x_n : n \in \mathbb{N}_+)$ is a Cauchy sequence in C and hence has a subsequence that converges to some $x \in C$. Then $x \in \bigcap_{n=1}^{\infty} C_n$ and since $\text{diam}(C_n) \rightarrow 0$ as $n \rightarrow \infty$ it follows that in fact, $\bigcap_{n=1}^{\infty} C_n = \{x\}$. Now, since \mathcal{U} covers C , there exists $U \in \mathcal{U}$ such that $x \in U$. Since U is open, there exists $r > 0$

such that $B(x, r) \subseteq U$. Now let $n \in \mathbb{N}_+$ be sufficiently large that $d(x, x_n) \leq r/2$ and $\text{diam}(C_n) < r/2$. Then $C_n \subseteq B(x, r) \subseteq U$, which contradicts the fact that C_n cannot be finitely covered by \mathcal{U} .

Hausdorff Measure and Dimension

Our last discussion is somewhat advanced, but is important for the study of certain random processes, particularly Brownian motion. The idea is to measure the “size” of a set in a metric space in a topological way, and then use this measure to define a type of “dimension”. We need a preliminary definition, using our convenient *cover* terminology. If (S, d) is a metric space, $A \subseteq S$, and $\delta \in (0, \infty)$, then a *countable δ cover* of A is a countable cover \mathcal{B} of A with the property that $\text{diam}(B) < \delta$ for each $B \in \mathcal{B}$.

Suppose again that (S, d) is a metric space and that $A \subseteq S$. For $\delta \in (0, \infty)$ and $k \in [0, \infty)$, define

$$H_\delta^k(A) = \inf \left\{ \sum_{B \in \mathcal{B}} [\text{diam}(B)]^k : \mathcal{B} \text{ is a countable } \delta \text{ cover of } A \right\} \quad (1.10.9)$$

The k -dimensional *Hausdorff measure* of A is

$$H^k(A) = \sup \{ H_\delta^k(A) : \delta > 0 \} = \lim_{\delta \downarrow 0} H_\delta^k(A) \quad (1.10.10)$$

Additional details

Note that if \mathcal{B} is a countable δ cover of A then it is also a countable ϵ cover of A for every $\epsilon > \delta$. This means that $H_\delta^k(A)$ is decreasing in $\delta \in (0, \infty)$ for fixed $k \in [0, \infty)$. Hence

$$\sup \{ H_\delta^k(A) : \delta > 0 \} = \lim_{\delta \downarrow 0} H_\delta^k(A) \quad (1.10.11)$$

Note that the k -dimensional Hausdorff measure is defined for every $k \in [0, \infty)$, not just nonnegative integers. Nonetheless, the integer dimensions are interesting. The 0-dimensional measure of A is the number of points in A . In Euclidean space, which we consider in (36), the measures of dimension 1, 2, and 3 are related to length, area, and volume, respectively.

Suppose again that (S, d) is a metric space and that $A \subseteq S$. The *Hausdorff dimension* of A is

$$\dim_H(A) = \inf \{ k \in [0, \infty) : H^k(A) = 0 \} \quad (1.10.12)$$

Of special interest, as before, is the case when $S = \mathbb{R}^n$ for some $n \in \mathbb{N}_+$ and d is the standard Euclidean distance, reviewed in (36). As you might guess, the Hausdorff dimension of a point is 0, the Hausdorff dimension of a “simple curve” is 1, the Hausdorff dimension of a “simple surface” is 2, and so on. But there are also sets with fractional Hausdorff dimension, and the stochastic process Brownian motion provides some fascinating examples. The graph of standard Brownian motion has Hausdorff dimension $3/2$ while the set of zeros has Hausdorff dimension $1/2$.

Examples and Special Cases

Normed Vector Spaces

A norm on a vector space generates a metric on the space in a very simple, natural way.

Suppose that $(S, +, \cdot)$ is a vector space, and that $\|\cdot\|$ is a norm on the space. Then d defined by $d(x, y) = \|y - x\|$ for $x, y \in S$ is a metric on S .

Proof

The metric axioms follow easily from the norm axioms.

1. The positive property for d follows since $\|x\| = 0$ if and only if $x = 0$.
2. The symmetric property for d follows since $\| -x \| = \|x\|$.
3. The triangle inequality for d follows from the triangle inequality for the norm: $\|x + y\| \leq \|x\| + \|y\|$.

On \mathbb{R}^n , we have a variety of norms, and hence a variety of metrics.

For $n \in \mathbb{N}_+$ and $k \in [1, \infty)$, the function d_k given below is a metric on \mathbb{R}^n :

$$d_k(\mathbf{x}, \mathbf{y}) = \left(\sum_{i=1}^n |x_i - y_i|^k \right)^{1/k}, \quad \mathbf{x} = (x_1, x_2, \dots, x_n), \mathbf{y} = (y_1, y_2, \dots, y_n) \in \mathbb{R}^n \quad (1.10.13)$$

Proof

This follows from the general result above, since $\|\cdot\|_k$ defined below is a norm on \mathbb{R}^n :

$$\|\mathbf{x}\|_k = \left(\sum_{i=1}^n |x_i|^k \right)^{1/k}, \quad \mathbf{x} = (x_1, x_2, \dots, x_n) \in \mathbb{R}^n \quad (1.10.14)$$

Of course the metric d_2 is *Euclidean distance*, named for Euclid of course. This is the most important one, in a practical sense because it's the usual one that we use in the real world, and in a mathematical sense because the associated norm corresponds to the standard inner product on \mathbb{R}^n given by

$$\langle \mathbf{x}, \mathbf{y} \rangle = \sum_{i=1}^n x_i y_i, \quad \mathbf{x} = (x_1, x_2, \dots, x_n), \mathbf{y} = (y_1, y_2, \dots, y_n) \in \mathbb{R}^n \quad (1.10.15)$$

For $n \in \mathbb{N}_+$, the function d_∞ defined below is a metric on \mathbb{R}^n :

$$d_\infty(\mathbf{x}, \mathbf{y}) = \max\{|x_i - y_i| : i \in \{1, 2, \dots, n\}\}, \quad \mathbf{x} = (x_1, x_2, \dots, x_n) \in \mathbb{R}^n \quad (1.10.16)$$

Proof

This follows from the general result above, since $\|\cdot\|_\infty$ defined below is a norm on \mathbb{R}^n :

$$\|\mathbf{x}\|_\infty = \max\{|x_i| : i \in \{1, 2, \dots, n\}\}, \quad \mathbf{x} = (x_1, x_2, \dots, x_n) \in \mathbb{R}^n \quad (1.10.17)$$

To justify the notation, recall that $\|\mathbf{x}\|_k \rightarrow \|\mathbf{x}\|_\infty$ as $k \rightarrow \infty$ for $\mathbf{x} \in \mathbb{R}^n$, and hence $d_k(\mathbf{x}, \mathbf{y}) \rightarrow d_\infty(\mathbf{x}, \mathbf{y})$ as $k \rightarrow \infty$ for $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$.

Figure 1.10.1: From inside out, the boundaries of the unit balls centered at the origin in \mathbb{R}^2 for the metrics d_k with $k \in \{1, 3/4, 2, 3, \infty\}$.

Suppose now that S is a nonempty set. Recall that the collection \mathcal{V} of all functions $f : S \rightarrow \mathbb{R}$ is a vector space under the usual pointwise definition of addition and scalar multiplication. That is, if $f, g \in \mathcal{V}$ and $c \in \mathbb{R}$, then $f + g \in \mathcal{V}$ and $cf \in \mathcal{V}$ are defined by $(f + g)(x) = f(x) + g(x)$ and $(cf)(x) = cf(x)$ for $x \in S$. Recall further that the collection \mathcal{U} of *bounded* functions $f : S \rightarrow \mathbb{R}$ is a vector subspace of \mathcal{V} , and moreover, $\|\cdot\|$ defined by $\|f\| = \sup\{|f(x)| : x \in S\}$ is a norm on \mathcal{U} , known as the *supremum norm*. It follows that \mathcal{U} is a metric space with the metric d defined by

$$d(f, g) = \|f - g\| = \sup\{|f(x) - g(x)| : x \in S\} \quad (1.10.18)$$

Vector spaces of bounded, real-valued functions, with the supremum norm are very important in the study of probability and stochastic processes. Note that the supremum norm on \mathcal{U} generalizes the [maximum norm](#) on \mathbb{R}^n , since we can think of a point in \mathbb{R}^n as a function from $\{1, 2, \dots, n\}$ into \mathbb{R} . Later, as part of our discussion on integration with respect to a positive measure, we will see how to generalize the k norms on \mathbb{R}^n to spaces of functions.

Products of Metric Spaces

If we have a finite number of metric spaces, then we can combine the individual metrics, together with an norm on the vector space \mathbb{R}^n , to create a norm on the Cartesian product space.

Suppose $n \in \{2, 3, \dots\}$, and that (S_i, d_i) is a metric space for each $i \in \{1, 2, \dots, n\}$. Suppose also that $\|\cdot\|$ is a norm on \mathbb{R}^n . Then the function d given as follows is a metric on $S = S_1 \times S_2 \times \dots \times S_n$:

$$d(\mathbf{x}, \mathbf{y}) = \|(d_1(x_1, y_1), d_2(x_2, y_2), \dots, d_n(x_n, y_n))\|, \quad \mathbf{x} = (x_1, x_2, \dots, x_n), \mathbf{y} = (y_1, y_2, \dots, y_n) \in S \quad (1.10.19)$$

Proof

1. Note that $d(\mathbf{x}, \mathbf{y}) = 0$ if and only if $d_i(x_i, y_i) = 0$ for $i \in \{1, 2, \dots, n\}$ if and only if $x_i = y_i$ for $i \in \{1, 2, \dots, n\}$ if and only if $\mathbf{x} = \mathbf{y}$.
2. Since $d_i(x_i, y_i) = d_i(y_i, x_i)$ for $i \in \{1, 2, \dots, n\}$ we have $d(\mathbf{x}, \mathbf{y}) = d(\mathbf{y}, \mathbf{x})$.
3. The triangle inequality follows from the triangle inequality for each metric, and the triangle inequality for the norm.

Graphs

Recall that a *graph* (in the combinatorial sense) consists of a countable set S of *vertices* and a set $E \subseteq S \times S$ of *edges*. In this discussion, we assume that the graph is *undirected* in the sense that $(x, y) \in E$ if and only if $(y, x) \in E$, and has no loops so that $(x, x) \notin E$ for $x \in S$. Finally, recall that a *path* of length $n \in \mathbb{N}_+$ from $x \in S$ to $y \in S$ is a sequence $(x_0, x_1, \dots, x_n) \in S^{n+1}$ such that $x_0 = x$, $x_n = y$, and $(x_{i-1}, x_i) \in E$ for $i \in \{1, 2, \dots, n\}$. The graph is *connected* if there exists a path of finite length between any two distinct vertices in S . Such a graph has a natural metric:

Suppose that $G = (S, E)$ is a connected graph. Then d defined as follows is a metric on S : $d(x, x) = 0$ for $x \in S$, and $d(x, y)$ is the length of the shortest path from x to y for distinct $x, y \in S$.

Proof

1. The positive property follows from the definition: $d(x, y) = 0$ if and only if $x = y$.
2. The symmetric property follows since the graph is undirected: $d(x, y) = d(y, x)$ for all $x, y \in S$.
3. For the triangle inequality, suppose that $x, y, z \in S$, and that $m = d(x, y)$ and $n = d(y, z)$. Then there is a path of length m from x to y and a path of length n from y to z . Concatenating the paths produces a path of length $m + n$ from x to z . But $d(x, z)$ is the length of the shortest such path, so it follows that $d(x, z) \leq m + n$.

The Discrete Topology

Suppose that S is a nonempty set. Recall that the discrete topology on S is $\mathcal{P}(S)$, the power set of S , so that every subset of S is open (and closed). The discrete topology is [metrizable](#), and there are lots of metrics that generate this topology.

Suppose again that S is a nonempty set. A metric d on S with the property that there exists $c \in (0, \infty)$ such that $d(x, y) \geq c$ for distinct $x, y \in S$ generates the discrete topology.

Proof

Note that $B(x, c) = \{x\}$ for $x \in S$. Hence $\{x\}$ is open for each $x \in S$.

So any metric that is bounded from below (for distinct points) generates the discrete topology. It's easy to see that there are such metrics.

Suppose again that S is a nonempty set. The function d on $S \times S$ defined by $d(x, x) = 0$ for $x \in S$ and $d(x, y) = 1$ for distinct $x, y \in S$ is a metric on S , known as the *discrete metric*. This metric generates the discrete topology.

Proof

Clearly $d(x, y) = 0$ if and only if $x = y$, and $d(x, y) = d(y, x)$ for $x, y \in S$, so the positive and symmetric properties hold. For the triangle inequality, suppose $x, y, z \in S$. The inequality trivially holds if the points are not distinct. If the points are distinct, then $d(x, z) = 1$ and $d(x, y) + d(y, z) = 2$.

In probability applications, the discrete topology is often appropriate when S is countable. Note also that the discrete metric is the graph distance if S is made into the *complete graph*, so that (x, y) is an edge for every pair of distinct vertices $x, y \in S$.

1.11: Measurable Spaces

In this section we discuss some topics from measure theory that are a bit more advanced than the topics in the early sections of this chapter. However, measure-theoretic ideas are essential for a deep understanding of probability, since probability is itself a measure. The most important of the definitions is the σ -algebra, a collection of subsets of a set with certain closure properties. Such collections play a fundamental role, even for applied probability, in encoding the state of information about a random experiment.

On the other hand, we won't be overly pedantic about measure-theoretic details in this text. Unless we say otherwise, we assume that all sets that appear are measurable (that is, members of the appropriate σ -algebras), and that all functions are measurable (relative to the appropriate σ -algebras).

Although this section is somewhat abstract, many of the proofs are straightforward. Be sure to try the proofs yourself before reading the ones in the text.

Algebras and σ -Algebras

Suppose that S is a set, playing the role of a universal set for a particular mathematical model. It is sometimes impossible to include *all* subsets of S in our model, particularly when S is uncountable. In a sense, the more sets that we include, the harder it is to have consistent theories. However, we almost always want the collection of admissible subsets to be *closed* under the basic set operations. This leads to some important definitions.

Algebras of Sets

Suppose that \mathcal{S} is a nonempty collection of subsets of S . Then \mathcal{S} is an *algebra* (or *field*) if it is closed under complement and union:

1. If $A \in \mathcal{S}$ then $A^c \in \mathcal{S}$.
2. If $A \in \mathcal{S}$ and $B \in \mathcal{S}$ then $A \cup B \in \mathcal{S}$.

If \mathcal{S} is an algebra of subsets of S then

1. $S \in \mathcal{S}$
2. $\emptyset \in \mathcal{S}$

Proof

1. Since \mathcal{S} is nonempty, there exists $A \in \mathcal{S}$. Hence $A^c \in \mathcal{S}$ so $S = A \cup A^c \in \mathcal{S}$.
2. $\emptyset = S^c \in \mathcal{S}$

Suppose that \mathcal{S} is an algebra of subsets of S and that $A_i \in \mathcal{S}$ for each i in a finite index set I .

1. $\bigcup_{i \in I} A_i \in \mathcal{S}$
2. $\bigcap_{i \in I} A_i \in \mathcal{S}$

Proof

1. This follows by induction on the number of elements in I .
2. This follows from (a) and DeMorgan's law. If $A_i \in \mathcal{S}$ for $i \in I$ then $A_i^c \in \mathcal{S}$ for $i \in I$. Therefore $\bigcup_{i \in I} A_i^c \in \mathcal{S}$ and hence $\bigcap_{i \in I} A_i = \left(\bigcup_{i \in I} A_i^c\right)^c \in \mathcal{S}$.

Thus it follows that an algebra of sets is closed under a finite number of set operations. That is, if we start with a finite number of sets in the algebra \mathcal{S} , and build a new set with a finite number of set operations (union, intersection, complement), then the new set is also in \mathcal{S} . However in many mathematical theories, probability in particular, this is not sufficient; we often need the collection of admissible subsets to be closed under a *countable* number of set operations.

σ -Algebras of Sets

Suppose that \mathcal{S} is a nonempty collection of subsets of S . Then \mathcal{S} is a σ -algebra (or σ -field) if the following axioms are satisfied:

1. If $A \in \mathcal{S}$ then $A^c \in \mathcal{S}$.
2. If $A_i \in \mathcal{S}$ for each i in a countable index set I , then $\bigcup_{i \in I} A_i \in \mathcal{S}$.

Clearly a σ -algebra of subsets is also an algebra of subsets, so the basic results for [algebras](#) above still hold. In particular, $S \in \mathcal{S}$ and $\emptyset \in \mathcal{S}$.

If $A_i \in \mathcal{S}$ for each i in a countable index set I , then $\bigcap_{i \in I} A_i \in \mathcal{S}$.

Proof

The proof is just like the one [above](#) for algebras. If $A_i \in \mathcal{S}$ for $i \in I$ then $A_i^c \in \mathcal{S}$ for $i \in I$. Therefore $\bigcup_{i \in I} A_i^c \in \mathcal{S}$ and hence $\bigcap_{i \in I} A_i = (\bigcup_{i \in I} A_i^c)^c \in \mathcal{S}$.

Thus a σ -algebra of subsets of S is closed under countable unions and intersections. This is the reason for the symbol σ in the name. As mentioned in the introductory paragraph, σ -algebras are of fundamental importance in mathematics generally and probability theory specifically, and thus deserve a special definition:

If S is a set and \mathcal{S} a σ -algebra of subsets of S , then the pair (S, \mathcal{S}) is called a *measurable space*.

The term *measurable space* will make more sense in the next chapter, when we discuss positive measures (and in particular, probability measures) on such spaces.

Suppose that S is a set and that \mathcal{S} is a finite algebra of subsets of S . Then \mathcal{S} is also a σ -algebra.

Proof

Any countable union of sets in \mathcal{S} reduces to a finite union.

However, there are algebras that are not σ -algebras. Here is the classic example:

Suppose that S is an infinite set. The collection of *finite and co-finite* subsets of S defined below is an algebra of subsets of S , but not a σ -algebra:

$$\mathcal{F} = \{A \subseteq S : A \text{ is finite or } A^c \text{ is finite}\} \quad (1.11.1)$$

Proof

$S \in \mathcal{F}$ since $S^c = \emptyset$ is finite. If $A \in \mathcal{F}$ then $A^c \in \mathcal{F}$ by the symmetry of the definition. Suppose that $A, B \in \mathcal{F}$. If A and B are both finite then $A \cup B$ is finite. If A^c or B^c is finite, then $(A \cup B)^c = A^c \cap B^c$ is finite. In either case, $A \cup B \in \mathcal{F}$. Thus \mathcal{F} is an algebra of subsets of S .

Since S is infinite, it contains a countably infinite subset $\{x_0, x_1, x_2, \dots\}$. Let $A_n = \{x_{2n}\}$ for $n \in \mathbb{N}$. Then A_n is finite, so $A_n \in \mathcal{F}$ for each $n \in \mathbb{N}$. Let $E = \bigcup_{n=0}^{\infty} A_n = \{x_0, x_2, x_4, \dots\}$. Then E is infinite by construction. Also $\{x_1, x_3, x_5, \dots\} \subseteq E^c$, so E^c is infinite as well. Hence $E \notin \mathcal{F}$ and so \mathcal{F} is not a σ -algebra.

General Constructions

Recall that $\mathcal{P}(S)$ denotes the collection of *all* subsets of S , called the *power set* of S . Trivially, $\mathcal{P}(S)$ is the largest σ -algebra of S . The power set is often the appropriate σ -algebra if S is countable, but as noted above, is sometimes too large to be useful if S is uncountable. At the other extreme, the smallest σ -algebra of S is given in the following result:

The collection $\{\emptyset, S\}$ is a σ -algebra.

Proof

Clearly $\{\emptyset, S\}$ is a finite algebra: S and \emptyset are complements of each other, and $S \cup \emptyset = S$. Hence $\{S, \emptyset\}$ is a σ -algebra by the [result above](#).

In many cases, we want to construct a σ -algebra that contains certain basic sets. The next two results show how to do this.

Suppose that \mathcal{S}_i is a σ -algebra of subsets of S for each i in a nonempty index set I . Then $\mathcal{S} = \bigcap_{i \in I} \mathcal{S}_i$ is also a σ -algebra of subsets of S .

Proof

The proof is completely straightforward. First, $S \in \mathcal{S}_i$ for each $i \in I$ so $S \in \mathcal{S}$. If $A \in \mathcal{S}$ then $A \in \mathcal{S}_i$ for each $i \in I$ and hence $A^c \in \mathcal{S}_i$ for each $i \in I$. Therefore $A^c \in \mathcal{S}$. Finally suppose that $A_j \in \mathcal{S}$ for each j in a countable index set J . Then $A_j \in \mathcal{S}_i$ for each $i \in I$ and $j \in J$ and therefore $\bigcup_{j \in J} A_j \in \mathcal{S}_i$ for each $i \in I$. It follows that $\bigcup_{j \in J} A_j \in \mathcal{S}$.

Note that no restrictions are placed on the index set I , other than it be nonempty, so in particular it may well be uncountable.

Suppose that S is a set and that \mathcal{B} is a collection of subsets of S . The σ -algebra generated by \mathcal{B} is

$$\sigma(\mathcal{B}) = \bigcap \{ \mathcal{S} : \mathcal{S} \text{ is a } \sigma\text{-algebra of subsets of } S \text{ and } \mathcal{B} \subseteq \mathcal{S} \} \quad (1.11.2)$$

If \mathcal{B} is countable then $\sigma(\mathcal{B})$ is said to be *countably generated*.

So the σ -algebra generated by \mathcal{B} is the intersection of all σ -algebras that contain \mathcal{B} , which by the previous result really is a σ -algebra. Note that the collection of σ -algebras in the intersection is not empty, since $\mathcal{P}(S)$ is in the collection. Think of the sets in \mathcal{B} as *basic sets* that we want to be measurable, but do not form a σ -algebra.

The σ -algebra $\sigma(\mathcal{B})$ is the smallest σ algebra containing \mathcal{B} .

1. $\mathcal{B} \subseteq \sigma(\mathcal{B})$
2. If \mathcal{S} is a σ -algebra of subsets of S and $\mathcal{B} \subseteq \mathcal{S}$ then $\sigma(\mathcal{B}) \subseteq \mathcal{S}$.

Proof

Both of these properties follows from the definition of $\sigma(\mathcal{B})$ as the intersection of all σ -algebras that contain \mathcal{B} .

Note that the conditions in the last theorem completely characterize $\sigma(\mathcal{B})$. If \mathcal{S}_1 and \mathcal{S}_2 satisfy the conditions, then by (a), $\mathcal{B} \subseteq \mathcal{S}_1$ and $\mathcal{B} \subseteq \mathcal{S}_2$. But then by (b), $\mathcal{S}_1 \subseteq \mathcal{S}_2$ and $\mathcal{S}_2 \subseteq \mathcal{S}_1$.

If A is a subset of S then $\sigma\{A\} = \{\emptyset, A, A^c, S\}$

Proof

Let $\mathcal{S} = \{\emptyset, A, A^c, S\}$. Clearly \mathcal{S} is an algebra: A and A^c are complements of each other, as are \emptyset and S . Also,

$$\begin{aligned} A \cup A^c &= A \cup S = A^c \cup S = S \cup S = \emptyset \cup S = S \\ A \cup \emptyset &= A \cup A = A \\ A^c \cup \emptyset &= A^c \cup A^c = A^c \\ \emptyset \cup \emptyset &= \emptyset \end{aligned}$$

Since \mathcal{S} is finite, it is a σ -algebra by (7). Next, $A \in \mathcal{S}$. Conversely, if \mathcal{T} is a σ -algebra and $A \in \mathcal{T}$ then of course $\emptyset, S, A^c \in \mathcal{T}$ so $\mathcal{S} \subseteq \mathcal{T}$. Hence $\mathcal{S} = \sigma\{A\}$

We can generalize the previous result. Recall that a collection of subsets $\mathcal{A} = \{A_i : i \in I\}$ is a *partition* of S if $A_i \cap A_j = \emptyset$ for $i, j \in I$ with $i \neq j$, and $\bigcup_{i \in I} A_i = S$.

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ is a countable partition of S into nonempty subsets. Then $\sigma(\mathcal{A})$ is the collection of all unions of sets in \mathcal{A} . That is,

$$\sigma(\mathcal{A}) = \left\{ \bigcup_{j \in J} A_j : J \subseteq I \right\} \quad (1.11.3)$$

Proof

Let $\mathcal{S} = \left\{ \bigcup_{j \in J} A_j : J \subseteq I \right\}$. Note that $S \in \mathcal{S}$ since $S = \bigcup_{i \in I} A_i$. Next, suppose that $B \in \mathcal{S}$. Then $B = \bigcup_{j \in J} A_j$ for some $J \subseteq I$. But then $B^c = \bigcup_{j \in J^c} A_j$, so $B^c \in \mathcal{S}$. Next, suppose that $B_k \in \mathcal{S}$ for $k \in K$ where K is a countable index set. Then for each $k \in K$ there exists $J_k \subseteq I$ such that $B_k = \bigcup_{j \in J_k} A_j$. But then $\bigcup_{k \in K} B_k = \bigcup_{k \in K} \bigcup_{j \in J_k} A_j = \bigcup_{j \in J} A_j$ where $J = \bigcup_{k \in K} J_k$. Hence $\bigcup_{k \in K} B_k \in \mathcal{S}$. Therefore \mathcal{S} is a σ -algebra of subsets of S . Trivially, $\mathcal{A} \subseteq \mathcal{S}$. If \mathcal{T} is a σ -algebra of subsets of S and $\mathcal{A} \subseteq \mathcal{T}$, then clearly $\bigcup_{j \in J} A_j \in \mathcal{T}$ for every $J \subseteq I$. Hence $\mathcal{S} \subseteq \mathcal{T}$.

A σ -algebra of this form is said to be *generated by a countable partition*. Note that since $A_i \neq \emptyset$ for $i \in I$, the representation of a set in $\sigma(\mathcal{A})$ as a union of sets in \mathcal{A} is unique. That is, if $J, K \subseteq I$ and $J \neq K$ then $\bigcup_{j \in J} A_j \neq \bigcup_{k \in K} A_k$. In particular, if there are n nonempty sets in \mathcal{A} , so that $\#(I) = n$, then there are 2^n subsets of I and hence 2^n sets in $\sigma(\mathcal{A})$.

Suppose now that $\mathcal{A} = \{A_1, A_2, \dots, A_n\}$ is a collection of n subsets of S (not necessarily disjoint). To describe the σ -algebra generated by \mathcal{A} we need a bit more notation. For $x = (x_1, x_2, \dots, x_n) \in \{0, 1\}^n$ (a bit string of length n), let $B_x = \bigcap_{i=1}^n A_i^{x_i}$ where $A_i^1 = A_i$ and $A_i^0 = A_i^c$.

In the setting above,

1. $\mathcal{B} = \{B_x : x \in \{0, 1\}^n\}$ partitions S .
2. $A_i = \bigcup \{B_x : x \in \{0, 1\}^n, x_i = 1\}$ for $i \in \{1, 2, \dots, n\}$.
3. $\sigma(\mathcal{A}) = \sigma(\mathcal{B}) = \{\bigcup_{x \in J} B_x : J \subseteq \{0, 1\}^n\}$.

Proof

1. Suppose that $x, y \in \{0, 1\}^n$ and that $x \neq y$. Without loss of generality we can suppose that for some $j \in \{1, 2, \dots, n\}$, $x_j = 0$ while $y_j = 1$. Then $B_x \subseteq A_j^c$ and $B_y \subseteq A_j$ so B_x and B_y are disjoint. Suppose that $s \in S$. Construct $x \in \{0, 1\}^n$ by $x_i = 1$ if $s \in A_i$ and $x_i = 0$ if $s \notin A_i$, for each $i \in \{1, 2, \dots, n\}$. Then by definition, $s \in B_x$. Hence \mathcal{B} partitions S .
2. Fix $i \in \{1, 2, \dots, n\}$. Again if $x \in \{0, 1\}^n$ and $x_i = 1$ then $B_x \subseteq A_i$. Hence $\bigcup \{B_x : x \in \{0, 1\}^n, x_i = 1\} \subseteq A_i$. Conversely, suppose $s \in A_i$. Define $y \in \{0, 1\}^n$ by $y_j = 1$ if $s \in A_j$ and $y_j = 0$ if $s \notin A_j$ for each $j \in \{1, 2, \dots, n\}$. Then $y_i = 1$ and $s \in B_y$. Hence $s \in \bigcup \{B_x : x \in \{0, 1\}^n, x_i = 1\}$.
3. Clearly, every σ -algebra of subsets of S that contains \mathcal{A} must also contain \mathcal{B} , and every σ -algebra of subsets of S that contains \mathcal{B} must also contain \mathcal{A} . It follows that $\sigma(\mathcal{A}) = \sigma(\mathcal{B})$. The characterization in terms of unions now follows from the [previous result](#).

Recall that there are 2^n bit strings of length n . The sets in \mathcal{A} are said to be in *general position* if the sets in \mathcal{B} are distinct (and hence there are 2^n of them) and are nonempty. In this case, there are 2^{2^n} sets in $\sigma(\mathcal{A})$.

Open the Venn diagram app. This app shows two subsets A and B of S in general position, and lists the 16 sets in $\sigma\{A, B\}$.

1. Select each of the 4 sets that partition S : $A \cap B$, $A \cap B^c$, $A^c \cap B$, $A^c \cap B^c$.
2. Select each of the other 12 sets in $\sigma\{A, B\}$ and note how each is a union of some of the sets in (a).

Sketch a Venn diagram with sets A_1, A_2, A_3 in general position. Identify the set B_x for each $x \in \{0, 1\}^3$.

If a σ -algebra is generated by a collection of basic sets, then each set in the σ -algebra is generated by a countable number of the basic sets.

Suppose that S is a set and \mathcal{B} a nonempty collection of subsets of S . Then

$$\sigma(\mathcal{B}) = \{A \subseteq S : A \in \sigma(\mathcal{C}) \text{ for some countable } \mathcal{C} \subseteq \mathcal{B}\} \quad (1.11.4)$$

Proof

Let \mathcal{S} denote the collection on the right. We first show that \mathcal{S} is a σ -algebra. First, pick $B \in \mathcal{B}$, which we can do since \mathcal{B} is nonempty. Then $S \in \sigma\{B\}$ so $S \in \mathcal{S}$. Let $A \in \mathcal{S}$ so that $A \in \sigma(\mathcal{C})$ for some countable $\mathcal{C} \subseteq \mathcal{B}$. Then $A^c \in \sigma(\mathcal{C})$ so $A^c \in \mathcal{S}$. Finally, suppose that $A_i \in \mathcal{S}$ for i in a countable index set I . Then for each $i \in I$, there exists a countable $\mathcal{C}_i \subseteq \mathcal{B}$ such that $A_i \in \sigma(\mathcal{C}_i)$. But then $\bigcup_{i \in I} \mathcal{C}_i$ is also countable and $\bigcup_{i \in I} A_i \in \sigma(\bigcup_{i \in I} \mathcal{C}_i)$. Hence $\bigcup_{i \in I} A_i \in \mathcal{S}$.

Next if $B \in \mathcal{B}$ then $B \in \sigma\{B\}$ so $B \in \mathcal{S}$. Hence $\sigma(\mathcal{B}) \subseteq \mathcal{S}$. Conversely, if $A \in \sigma(\mathcal{C})$ for some countable $\mathcal{C} \subseteq \mathcal{B}$ then trivially $A \in \sigma(\mathcal{B})$.

A σ -algebra on a set naturally leads to a σ -algebra on a subset.

Suppose that (S, \mathcal{S}) is a measurable space, and that $R \subseteq S$. Let $\mathcal{R} = \{A \cap R : A \in \mathcal{S}\}$. Then

1. \mathcal{R} is a σ -algebra of subsets of R .
2. If $R \in \mathcal{S}$ then $\mathcal{R} = \{B \in \mathcal{S} : B \subseteq R\}$.

Proof

1. First, $S \in \mathcal{S}$ and $S \cap R = R$ so $R \in \mathcal{R}$. Next suppose that $B \in \mathcal{R}$. Then there exists $A \in \mathcal{S}$ such that $B = A \cap R$. But then $A^c \in \mathcal{S}$ and $R \setminus B = R \cap B^c = R \cap A^c$, so $R \setminus B \in \mathcal{R}$. Finally, suppose that $B_i \in \mathcal{R}$ for i in a countable index set I . For each $i \in I$ there exists $A_i \in \mathcal{S}$ such that $B_i = A_i \cap R$. But then $\bigcup_{i \in I} A_i \in \mathcal{S}$ and $\bigcup_{i \in I} B_i = (\bigcup_{i \in I} A_i) \cap R$, so $\bigcup_{i \in I} B_i \in \mathcal{R}$.
2. Suppose that $R \in \mathcal{S}$. Then $A \cap R \in \mathcal{S}$ for every $A \in \mathcal{S}$, and of course, $A \cap R \subseteq R$. Conversely, if $B \in \mathcal{S}$ and $B \subseteq R$ then $B = B \cap R$ so $B \in \mathcal{R}$.

The σ -algebra \mathcal{R} is the σ -algebra on R induced by \mathcal{S} . The following construction is useful for counterexamples. Compare this example with the one for [finite and co-finite sets](#).

Let S be a nonempty set. The collection of *countable and co-countable* subsets of S is

$$\mathcal{C} = \{A \subseteq S : A \text{ is countable or } A^c \text{ is countable}\} \quad (1.11.5)$$

1. \mathcal{C} is a σ -algebra
2. $\mathcal{C} = \sigma\{\{x\} : x \in S\}$, the σ -algebra generated by the singleton sets.

Proof

1. First, $S \in \mathcal{C}$ since $S^c = \emptyset$ is countable. If $A \in \mathcal{C}$ then $A^c \in \mathcal{C}$ by the symmetry of the definition. Suppose that $A_i \in \mathcal{C}$ for each i in a countable index set I . If A_i is countable for each $i \in I$ then $\bigcup_{i \in I} A_i$ is countable. If A_j^c is countable for some $j \in I$ then $(\bigcup_{i \in I} A_i)^c = \bigcap_{i \in I} A_i^c \subseteq A_j^c$ is countable. In either case, $\bigcup_{i \in I} A_i \in \mathcal{C}$.
2. Let $\mathcal{D} = \sigma\{\{x\} : x \in S\}$. Clearly $\{x\} \in \mathcal{C}$ for $x \in S$. Hence $\mathcal{D} \subseteq \mathcal{C}$. Conversely, suppose that $A \in \mathcal{C}$. If A is countable, then $A = \bigcup_{x \in A} \{x\} \in \mathcal{D}$. If A^c is countable, then by an identical argument, $A^c \in \mathcal{D}$ and hence $A \in \mathcal{D}$.

Of course, if S is itself countable then $\mathcal{C} = \mathcal{P}(S)$. On the other hand, if S is uncountable, then there exists $A \subseteq S$ such that A and A^c are uncountable. Thus, $A \notin \mathcal{C}$, but $A = \bigcup_{x \in A} \{x\}$, and of course $\{x\} \in \mathcal{C}$. Thus, we have an example of a σ -algebra that is not closed under general unions.

Topology and Measure

One of the most important ways to generate a σ -algebra is by means of topology. Recall that a topological space consists of a set S and a topology \mathcal{S} , the collection of *open* subsets of S . Most spaces that occur in probability and stochastic processes are topological spaces, so it's crucial that the topological and measure-theoretic structures are compatible.

Suppose that (S, \mathcal{S}) is a topological space. Then $\sigma(\mathcal{S})$ is the *Borel σ -algebra* on S , and $(S, \sigma(\mathcal{S}))$ is a *Borel measurable space*.

So the Borel σ -algebra on S , named for Émile Borel is generated by the open subsets of S . Thus, a *topological space* (S, \mathcal{S}) naturally leads to a *measurable space* $(S, \sigma(\mathcal{S}))$. Since a closed set is simply the complement of an open set, the Borel σ -algebra contains the closed sets as well (and in fact is generated by the closed sets). Here are some other sets that are in the Borel σ -algebra:

Suppose again that (S, \mathcal{S}) is a topological space and that I is a countable index set.

1. If A_i is open for each $i \in I$ then $\bigcap_{i \in I} A_i \in \sigma(\mathcal{S})$. Such sets are called G_δ sets.
2. If A_i is closed for each $i \in I$ then $\bigcup_{i \in I} A_i \in \sigma(\mathcal{S})$. Such sets are called F_σ sets.
3. If (S, \mathcal{S}) is Hausdorff then $\{x\} \in \mathcal{S}$ for every $x \in S$.

Proof

1. This follows direction from the closure property for [intersections](#).
2. This follows from the [definition](#).
3. This follows since $\{x\}$ is closed for each $x \in S$ if the topology is Hausdorff.

In terms of part (c), recall that a topological space is *Hausdorff*, named for Felix Hausdorff, if the topology can distinguish individual points. Specifically, if $x, y \in S$ are distinct then there exist disjoint open sets U, V with $x \in U$ and $y \in V$. This is a

very basic property possessed by almost all topological spaces that occur in applications. A simple corollary of (c) is that if the topological space (S, \mathcal{S}) is Hausdorff then $A \in \sigma(\mathcal{S})$ for every countable $A \subseteq S$.

Let's note the extreme cases. If S has the *discrete topology* $\mathcal{P}(S)$, so that every set is open (and closed), then of course the Borel σ -algebra is also $\mathcal{P}(S)$. As noted above, this is often the appropriate σ -algebra if S is countable, but is often too large if S is uncountable. If S has the trivial topology $\{S, \emptyset\}$, then the Borel σ -algebra is also $\{S, \emptyset\}$, and so is also trivial.

Recall that a *base* for a topological space (S, \mathcal{T}) is a collection $\mathcal{B} \subseteq \mathcal{T}$ with the property that every set in \mathcal{T} is a union of a collection of sets in \mathcal{B} . In short, every open set is a union of some of the basic open sets.

Suppose that (S, \mathcal{S}) is a topological space with a countable base \mathcal{B} . Then $\sigma(\mathcal{B}) = \sigma(\mathcal{S})$.

Proof

Since $\mathcal{B} \subseteq \mathcal{S}$ it follows trivially that $\sigma(\mathcal{B}) \subseteq \sigma(\mathcal{S})$. Conversely, if $U \in \mathcal{S}$, there exists a collection of sets in \mathcal{B} whose union is U . Since \mathcal{B} is countable, $U \in \sigma(\mathcal{B})$.

The topological spaces that occur in probability and stochastic processes are usually assumed to have a countable base (along with other nice properties such as the Hausdorff property and locally compactness). The σ -algebra used for such a space is usually the Borel σ -algebra, which by the previous result, is countably generated.

Measurable Functions

Recall that a set usually comes with a σ -algebra of admissible subsets. A natural requirement on a function is that the inverse image of an admissible set in the range space be admissible in the domain space. Here is the formal definition.

Suppose that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces. A function $f : S \rightarrow T$ is *measurable* if $f^{-1}(A) \in \mathcal{S}$ for every $A \in \mathcal{T}$.

If the σ -algebra in the range space is generated by a collection of basic sets, then to check the measurability of a function, we need only consider inverse images of basic sets:

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces, and that $\mathcal{T} = \sigma(\mathcal{B})$ for a collection of subsets \mathcal{B} of T . Then $f : S \rightarrow T$ is measurable if and only if $f^{-1}(B) \in \mathcal{S}$ for every $B \in \mathcal{B}$.

Proof

First $\mathcal{B} \subseteq \mathcal{T}$, so if $f : S \rightarrow T$ is measurable then the condition in the theorem trivially holds. Conversely, suppose that the condition in the theorem holds, and let $\mathcal{U} = \{A \in \mathcal{T} : f^{-1}(A) \in \mathcal{S}\}$. Then $T \in \mathcal{U}$ since $f^{-1}(T) = S \in \mathcal{S}$. If $A \in \mathcal{U}$ then $f^{-1}(A^c) = [f^{-1}(A)]^c \in \mathcal{S}$, so $A^c \in \mathcal{U}$. If $A_i \in \mathcal{U}$ for i in a countable index set I , then $f^{-1}(\bigcup_{i \in I} A_i) = \bigcup_{i \in I} f^{-1}(A_i) \in \mathcal{S}$, and hence $\bigcup_{i \in I} A_i \in \mathcal{U}$. Thus \mathcal{U} is a σ -algebra of subsets of T . But $\mathcal{B} \subseteq \mathcal{U}$ by assumption, so $\mathcal{T} = \sigma(\mathcal{B}) \subseteq \mathcal{U}$. Of course $\mathcal{U} \subseteq \mathcal{T}$ by definition, so $\mathcal{U} = \mathcal{T}$ and hence f is measurable.

If you have reviewed the section on topology then you may have noticed a striking parallel between the definition of *continuity* for functions on topological spaces and the definition of *measurability* for functions on measurable spaces: A function from one topological space to another is *continuous* if the inverse image of an open set in the range space is open in the domain space. A function from one measurable space to another is *measurable* if the inverse image of a measurable set in the range space is measurable in the domain space. If we start with topological spaces, which we often do, and use the Borel σ -algebras to get measurable spaces, then we get the following (hardly surprising) connection.

Suppose that (S, \mathcal{S}) and (T, \mathcal{T}) are topological spaces, and that we give S and T the Borel σ -algebras $\sigma(\mathcal{S})$ and $\sigma(\mathcal{T})$ respectively. If $f : S \rightarrow T$ is continuous, then f is measurable.

Proof

If $V \in \mathcal{T}$ then $f^{-1}(V) \in \mathcal{S} \subseteq \sigma(\mathcal{S})$. Hence f is measurable by the previous theorem.

Measurability is preserved under composition, the most important method for combining functions.

Suppose that (R, \mathcal{R}) , (S, \mathcal{S}) , and (T, \mathcal{T}) are measurable spaces. If $f : R \rightarrow S$ is measurable and $g : S \rightarrow T$ is measurable, then $g \circ f : R \rightarrow T$ is measurable.

Proof

If $A \in \mathcal{T}$ then $g^{-1}(A) \in \mathcal{S}$ since g is measurable, and hence $(g \circ f)^{-1}(A) = f^{-1}[g^{-1}(A)] \in \mathcal{R}$ since f is measurable.

If T is given the smallest possible σ -algebra or if S is given the largest one, then any function from S into T is measurable.

Every function $f : S \rightarrow T$ is measurable in each of the following cases:

1. $\mathcal{T} = \{\emptyset, T\}$ and \mathcal{S} is an arbitrary σ -algebra of subsets of S
2. $\mathcal{S} = \mathcal{P}(S)$ and \mathcal{T} is an arbitrary σ -algebra of subsets of T .

Proof

1. Suppose that $\mathcal{T} = \{\emptyset, T\}$ and that \mathcal{S} is an arbitrary σ -algebra on S . If $f : S \rightarrow T$, then $f^{-1}(T) = S \in \mathcal{S}$ and $f^{-1}(\emptyset) = \emptyset \in \mathcal{S}$ so f is measurable.
2. Suppose that $\mathcal{S} = \mathcal{P}(S)$ and that \mathcal{T} is an arbitrary σ -algebra on T . If $f : S \rightarrow T$, then trivially $f^{-1}(A) \in \mathcal{S}$ for every $A \in \mathcal{T}$ so f is measurable.

When there are several σ -algebras for the same set, then we use the phrase *with respect to* so that we can be precise. If a function is measurable with respect to a given σ -algebra on its domain, then it's measurable with respect to any larger σ -algebra on this space. If the function is measurable with respect to a σ -algebra on the range space then it's measurable with respect to any smaller σ -algebra on this space.

Suppose that S has σ -algebras \mathcal{R} and \mathcal{S} with $\mathcal{R} \subseteq \mathcal{S}$, and that T has σ -algebras \mathcal{T} and \mathcal{U} with $\mathcal{T} \subseteq \mathcal{U}$. If $f : S \rightarrow T$ is measurable with respect to \mathcal{R} and \mathcal{U} , then f is measurable with respect to \mathcal{S} and \mathcal{T} .

Proof

If $A \in \mathcal{T}$ then $A \in \mathcal{U}$. Hence $f^{-1}(A) \in \mathcal{R}$ so $f^{-1}(A) \in \mathcal{S}$.

The following construction is particularly important in probability theory:

Suppose that S is a set and (T, \mathcal{T}) is a measurable space. Suppose also that $f : S \rightarrow T$ and define $\sigma(f) = \{f^{-1}(A) : A \in \mathcal{T}\}$. Then

1. $\sigma(f)$ is a σ -algebra on S .
2. $\sigma(f)$ is the smallest σ -algebra on S that makes f measurable.

Proof

1. The key to the proof is that the inverse image preserves all set operations. First, $S \in \sigma(f)$ since $T \in \mathcal{T}$ and $f^{-1}(T) = S$. If $B \in \sigma(f)$ then $B = f^{-1}(A)$ for some $A \in \mathcal{T}$. But then $A^c \in \mathcal{T}$ and hence $B^c = f^{-1}(A^c) \in \sigma(f)$. Finally, suppose that $B_i \in \sigma(f)$ for i in a countable index set I . Then for each $i \in I$ there exists $A_i \in \mathcal{T}$ such that $B_i = f^{-1}(A_i)$. But then $\bigcup_{i \in I} A_i \in \mathcal{T}$ and $\bigcup_{i \in I} B_i = f^{-1}(\bigcup_{i \in I} A_i)$. Hence $\bigcup_{i \in I} B_i \in \sigma(f)$.
2. If \mathcal{S} is a σ -algebra on S and f is measurable with respect to \mathcal{S} and \mathcal{T} , then by definition $f^{-1}(A) \in \mathcal{S}$ for every $A \in \mathcal{T}$, so $\sigma(f) \subseteq \mathcal{S}$.

Appropriately enough, $\sigma(f)$ is called the σ -algebra generated by f . Often, S will have a given σ -algebra \mathcal{S} and f will be measurable with respect to \mathcal{S} and \mathcal{T} . In this case, $\sigma(f) \subseteq \mathcal{S}$. We can generalize to an arbitrary collection of functions on S .

Suppose S is a set and that (T_i, \mathcal{T}_i) is a measurable space for each i in a nonempty index set I . Suppose also that $f_i : S \rightarrow T_i$ for each $i \in I$. The σ -algebra generated by this collection of functions is

$$\sigma\{f_i : i \in I\} = \sigma\{\sigma(f_i) : i \in I\} = \sigma\{f_i^{-1}(A) : i \in I, A \in \mathcal{T}_i\} \quad (1.11.6)$$

Again, this is the smallest σ -algebra on S that makes f_i measurable for each $i \in I$.

Product Sets

Product sets arise naturally in the form of the higher-dimensional Euclidean spaces \mathbb{R}^n for $n \in \{2, 3, \dots\}$. In addition, product spaces are particularly important in probability, where they are used to describe the spaces associated with sequences of random variables. More general product spaces arise in the study of stochastic processes. We start with the product of two sets; the generalization to products of n sets and to general products is straightforward, although the notation gets more complicated.

Suppose that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces. The *product σ -algebra* on $S \times T$ is

$$\mathcal{S} \otimes \mathcal{T} = \sigma\{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\} \quad (1.11.7)$$

So the definition is natural: the product σ -algebra is generated by products of measurable sets. Our next goal is to consider the measurability of functions defined on, or mapping into, product spaces. Of basic importance are the projection functions. If S and T are sets, let $p_1 : S \times T \rightarrow S$ and $p_2 : S \times T \rightarrow T$ be defined by $p_1(x, y) = x$ and $p_2(x, y) = y$ for $(x, y) \in S \times T$. Recall that p_1 is the *projection onto the first coordinate* and p_2 is the *projection onto the second coordinate*. The product σ algebra is the smallest σ -algebra that makes the projections measurable:

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces. Then $\mathcal{S} \otimes \mathcal{T} = \sigma\{p_1, p_2\}$.

Proof

If $A \in \mathcal{S}$ then $p_1^{-1}(A) = A \times T \in \mathcal{S} \otimes \mathcal{T}$. Similarly, if $B \in \mathcal{T}$ then $p_2^{-1}(B) = S \times B \in \mathcal{S} \otimes \mathcal{T}$. Hence p_1 and p_2 are measurable, so $\sigma\{p_1, p_2\} \subseteq \mathcal{S} \otimes \mathcal{T}$. Conversely, if $A \in \mathcal{S}$ and $B \in \mathcal{T}$ then $A \times B = p_1^{-1}(A) \cap p_2^{-1}(B) \in \sigma\{p_1, p_2\}$. Since sets of this form generate the product σ -algebra, we have $\mathcal{S} \otimes \mathcal{T} \subseteq \sigma\{p_1, p_2\}$.

Projection functions make it easy to study functions mapping into a product space.

Suppose that (R, \mathcal{R}) , (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces, and that $S \times T$ is given the product σ -algebra $\mathcal{S} \otimes \mathcal{T}$. Suppose also that $f : R \rightarrow S \times T$, so that $f(x) = (f_1(x), f_2(x))$ for $x \in R$, where $f_1 : R \rightarrow S$ and $f_2 : R \rightarrow T$ are the *coordinate functions*. Then f is measurable if and only if f_1 and f_2 are measurable.

Proof

Note that $f_1 = p_1 \circ f$ and $f_2 = p_2 \circ f$. So if f is measurable then f_1 and f_2 are compositions of measurable functions, and hence are measurable. Conversely, suppose that f_1 and f_2 are measurable. If $A \in \mathcal{S}$ and $B \in \mathcal{T}$ then $f^{-1}(A \times B) = f_1^{-1}(A) \cap f_2^{-1}(B) \in \mathcal{R}$. Since products of measurable sets generate $\mathcal{S} \otimes \mathcal{T}$, it follows that f is measurable.

Our next goal is to consider cross sections of sets in a product space and cross sections of functions defined on a product space. It will help to introduce some new functions, which in a sense are complementary to the projection functions.

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces, and that $S \times T$ is given the product σ -algebra $\mathcal{S} \otimes \mathcal{T}$.

1. For $x \in S$ the function $1_x : T \rightarrow S \times T$, defined by $1_x(y) = (x, y)$ for $y \in T$, is measurable.
2. For $y \in T$ the function $2_y : S \rightarrow S \times T$, defined by $2_y(x) = (x, y)$ for $x \in S$, is measurable.

Proof

To show that the functions are measurable, it suffices to consider inverse images of products of measurable sets, since such sets generate $\mathcal{S} \otimes \mathcal{T}$. Thus, let $A \in \mathcal{S}$ and $B \in \mathcal{T}$.

1. For $x \in S$ note that $1_x^{-1}(A \times B)$ is B if $x \in A$ and is \emptyset if $x \notin A$. In either case, $1_x^{-1}(A \times B) \in \mathcal{T}$.
2. Similarly, for $y \in T$ note that $2_y^{-1}(A \times B)$ is A if $y \in B$ and is \emptyset if $y \notin B$. In either case, $2_y^{-1}(A \times B) \in \mathcal{S}$.

Now our work is easy.

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces, and that $C \in \mathcal{S} \otimes \mathcal{T}$. Then

1. For $x \in S$, $\{y \in T : (x, y) \in C\} \in \mathcal{T}$.
2. For $y \in T$, $\{x \in S : (x, y) \in C\} \in \mathcal{S}$.

Proof

These result follow immediately from the measurability of the functions 1_x and 2_y :

1. For $x \in S$, $1_x^{-1}(C) = \{y \in T : (x, y) \in C\}$.
2. For $y \in T$, $2_y^{-1}(C) = \{x \in S : (x, y) \in C\}$.

The set in (a) is the *cross section of C in the first coordinate at x* , and the set in (b) is the *cross section of C in the second coordinate at y* . As a simple corollary to the theorem, note that if $A \subseteq S$, $B \subseteq T$ and $A \times B \in \mathcal{S} \otimes \mathcal{T}$ then $A \in \mathcal{S}$ and $B \in \mathcal{T}$. That is, the only measurable product sets are products of measurable sets. Here is the measurability result for cross-sectional functions:

Suppose again that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces, and that $S \times T$ is given the product σ -algebra $\mathcal{S} \otimes \mathcal{T}$. Suppose also that (U, \mathcal{U}) is another measurable space, and that $f : S \times T \rightarrow U$ is measurable. Then

1. The function $y \mapsto f(x, y)$ from T to U is measurable for each $x \in S$.
2. The function $x \mapsto f(x, y)$ from S to U is measurable for each $y \in T$.

Proof

Note that the function in (a) is just $f \circ 1_x$, and the function in (b) is just $f \circ 2_y$, both are compositions of measurable functions

The results for products of two spaces generalize in a completely straightforward way to a product of n spaces.

Suppose $n \in \mathbb{N}_+$ and that (S_i, \mathcal{S}_i) is a measurable space for each $i \in \{1, 2, \dots, n\}$. The *product σ -algebra* on the Cartesian product set $S_1 \times S_2 \times \dots \times S_n$ is

$$\mathcal{S}_1 \otimes \mathcal{S}_2 \otimes \dots \otimes \mathcal{S}_n = \sigma \{A_1 \times A_2 \times \dots \times A_n : A_i \in \mathcal{S}_i \text{ for all } i \in \{1, 2, \dots, n\}\} \quad (1.11.8)$$

So again, the product σ -algebra is generated by products of measurable sets. Results analogous to the theorems above hold. In the special case that $(S_i, \mathcal{S}_i) = (S, \mathcal{S})$ for $i \in \{1, 2, \dots, n\}$, the Cartesian product becomes S^n and the corresponding product σ -algebra is denoted \mathcal{S}^n . The notation is natural, but potentially confusing. Note that \mathcal{S}^n is not the Cartesian product of \mathcal{S} n times, but rather the σ -algebra generated by sets of the form $A_1 \times A_2 \times \dots \times A_n$ where $A_i \in \mathcal{S}$ for $i \in \{1, 2, \dots, n\}$.

We can also extend these ideas to a general product. To recall the definition, suppose that S_i is a set for each i in a nonempty index set I . The product set $\prod_{i \in I} S_i$ consists of all functions $x : I \rightarrow \bigcup_{i \in I} S_i$ such that $x(i) \in S_i$ for each $i \in I$. To make the notation look more like a simple Cartesian product, we often write x_i instead of $x(i)$ for the value of a function in the product set at $i \in I$. The next definition gives the appropriate σ -algebra for the product set.

Suppose that (S_i, \mathcal{S}_i) is a measurable space for each i in a nonempty index set I . The *product σ -algebra* on the product set $\prod_{i \in I} S_i$ is

$$\sigma \left\{ \prod_{i \in I} A_i : A_i \in \mathcal{S}_i \text{ for each } i \in I \text{ and } A_i = S_i \text{ for all but finitely many } i \in I \right\} \quad (1.11.9)$$

If you have reviewed the section on topology, the definition should look familiar. If the spaces were *topological spaces* instead of *measurable spaces*, with \mathcal{S}_i the topology of S_i for $i \in I$, then the set of products in the displayed expression above is a base for the product topology on $\prod_{i \in I} S_i$.

The definition can also be understood in terms of projections. Recall that the *projection* onto coordinate $j \in I$ is the function $p_j : \prod_{i \in I} S_i \rightarrow S_j$ given by $p_j(x) = x_j$. The product σ -algebra is the smallest σ -algebra on the product set that makes all of the projections measurable.

Suppose again that (S_i, \mathcal{S}_i) is a measurable space for each i in a nonempty index set I , and let \mathfrak{S} denote the product σ -algebra on the product set $S_I = \prod_{i \in I} S_i$. Then $\mathfrak{S} = \sigma\{p_i : i \in I\}$.

Proof

Let $j \in I$ and $A \in \mathcal{S}_j$. Then $p_j^{-1}(A) = \prod_{i \in I} A_i$ where $A_i = S_i$ for $i \neq j$ and $A_j = A$. This set is in \mathfrak{S} so p_j is measurable. Hence $\sigma\{p_i : i \in I\} \subseteq \mathfrak{S}$. For the other direction, consider a product set $\prod_{i \in I} A_i$ where $A_i = S_i$ except for $i \in J$, where

$J \subseteq I$ is finite. Then $\prod_{i \in I} A_i = \bigcap_{j \in J} p_j^{-1}(A_j)$. This set is in $\sigma\{p_i : i \in I\}$. Product sets of this form generate \mathfrak{S} so it follows that $\mathfrak{S} \subseteq \sigma\{p_i : i \in I\}$.

In the special case that (S, \mathcal{S}) is a fixed measurable space and $(S_i, \mathcal{S}_i) = (S, \mathcal{S})$ for all $i \in I$, the product set $\prod_{i \in I} S$ is just the collection of functions from I into S , often denoted S^I . The product σ -algebra is then denoted \mathcal{S}^I , a notation that is natural, but again potentially confusing. Here is the main measurability result for a function mapping into a product space.

Suppose that (R, \mathcal{R}) is a measurable space, and that (S_i, \mathcal{S}_i) is a measurable space for each i in a nonempty index set I . As before, let $\prod_{i \in I} S_i$ have the product σ -algebra. Suppose now that $f : R \rightarrow \prod_{i \in I} S_i$. For $i \in I$ let $f_i : R \rightarrow S_i$ denote the i th coordinate function of f , so that $f_i(x) = [f(x)]_i$ for $x \in R$. Then f is measurable if and only if f_i is measurable for each $i \in I$.

Proof

Suppose that f is measurable. For $i \in I$ note that $f_i = p_i \circ f$ is a composition of measurable functions, and hence is measurable. Conversely, suppose that f_i is measurable for each $i \in I$. To show that measurability of f we need only consider inverse images of sets that generate the product σ -algebra. Thus, suppose that $A_j \in \mathcal{S}_j$ for j in a finite subset $J \subseteq I$, and let $A_i = S_i$ for $i \in I - J$. Then $f^{-1}(\prod_{i \in I} A_i) = \bigcap_{j \in J} f_j^{-1}(A_j)$. This set is in \mathcal{R} since the intersection is over a finite index set.

Just as with the product of two sets, cross-sectional sets and functions are measurable with respect to the product measure. Again, it's best to work with some special functions.

Suppose that (S_i, \mathcal{S}_i) is a measurable space for each i in an index set I with at least two elements. For $j \in I$ and $u \in S_j$, define the function $j_u : \prod_{i \in I - \{j\}} S_i \rightarrow \prod_{i \in I} S_i$ by $j_u(x) = y$ where $y_i = x_i$ for $i \neq j$ and $y_j = u$. Then j_u is measurable with respect to the product σ -algebras.

Proof

Once again, it suffices to consider the inverse image of the sets that generate the product σ -algebra. So suppose $A_i \in \mathcal{S}_i$ for $i \in I$ with $A_i = S_i$ for all but finitely many $i \in I$. Then $j_u^{-1}(\prod_{i \in I} A_i) = \prod_{i \in I - \{j\}} A_i$ if $u \in A_j$, and the inverse image is \emptyset otherwise. In either case, $j_u^{-1}(\prod_{i \in I} A_i)$ is in the product σ -algebra on $\prod_{i \in I - \{j\}} S_i$.

In words, for $j \in I$ and $u \in S_j$, the function j_u takes a point in the product set $\prod_{i \in I - \{j\}} S_i$ and assigns u to coordinate j to give a point in $\prod_{i \in I} S_i$. If $A \subseteq \prod_{i \in I} S_i$, then $j_u^{-1}(A)$ is the cross section of A in coordinate j at u . So it follows immediately from the previous result that the cross sections of a measurable set are measurable. Cross sections of measurable functions are also measurable. Suppose that (T, \mathcal{T}) is another measurable space, and that $f : \prod_{i \in I} S_i \rightarrow T$ is measurable. The cross section of f in coordinate $j \in I$ at $u \in S_j$ is simply $f \circ j_u : S_{I - \{j\}} \rightarrow T$, a composition of measurable functions.

However, a non-measurable set can have measurable cross sections, even in a product of two spaces.

Suppose that S is an uncountable set with the σ -algebra \mathcal{C} of countable and co-countable sets as in (21). Consider $S \times S$ with the product σ -algebra $\mathcal{C} \otimes \mathcal{C}$. Let $D = \{(x, x) : x \in S\}$, the *diagonal* of $S \times S$. Then D has measurable cross sections, but D is not measurable.

Proof

For $x \in S$, the cross section of D in the first coordinate at x is $\{y \in S : (x, y) \in D\} = \{x\} \in \mathcal{C}$. Similarly, for $y \in S$, the cross section of D in the second coordinate at y is $\{x \in S : (x, y) \in D\} = \{y\} \in \mathcal{C}$. But D cannot be generated by a countable collection of sets of the form $A \times B$ with $A, B \in \mathcal{C}$, so $D \notin \mathcal{C} \otimes \mathcal{C}$, by the result above.

Special Cases

Most of the sets encountered in applied probability are either countable, or subsets of \mathbb{R}^n for some n , or more generally, subsets of a product of a countable number of sets of these types. In the study of stochastic processes, various spaces of functions play an important role. In this subsection, we will explore the most important special cases.

Discrete Spaces

If S is countable and $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S , then (S, \mathcal{S}) is a *discrete measurable space*.

Thus if (S, \mathcal{S}) is discrete, all subsets of S are measurable and every function from S to another measurable space is measurable. The power set is also the discrete topology on S , so \mathcal{S} is a Borel σ -algebra as well. As a topological space, (S, \mathcal{S}) is complete, locally compact, Hausdorff, and since S is countable, separable. Moreover, the discrete topology corresponds to the discrete metric d , defined by $d(x, x) = 0$ for $x \in S$ and $d(x, y) = 1$ for $x, y \in S$ with $x \neq y$.

Euclidean Spaces

Recall that for $n \in \mathbb{N}_+$, the Euclidean topology on \mathbb{R}^n is generated by the standard Euclidean metric d_n given by

$$d_n(\mathbf{x}, \mathbf{y}) = \sqrt{\sum_{i=1}^n (x_i - y_i)^2}, \quad \mathbf{x} = (x_1, x_2, \dots, x_n), \mathbf{y} = (y_1, y_2, \dots, y_n) \in \mathbb{R}^n \quad (1.11.10)$$

With this topology, \mathbb{R}^n is complete, connected, locally compact, Hausdorff, and separable.

For $n \in \mathbb{N}_+$, the n -dimensional *Euclidean measurable space* is $(\mathbb{R}^n, \mathcal{R}_n)$ where \mathcal{R}_n is the Borel σ -algebra corresponding to the standard Euclidean topology on \mathbb{R}^n .

The one-dimensional case is particularly important. In this case, the standard Euclidean metric d is given by $d(x, y) = |x - y|$ for $x, y \in \mathbb{R}$. The Borel σ -algebra \mathcal{R} can be generated by various collections of intervals.

Each of the following collections generates \mathcal{R} .

1. $\mathcal{B}_1 = \{I \subseteq \mathbb{R} : I \text{ is an interval}\}$
2. $\mathcal{B}_2 = \{(a, b] : a, b \in \mathbb{R}, a < b\}$
3. $\mathcal{B}_3 = \{(-\infty, b] : b \in \mathbb{R}\}$

Proof

The proof involves showing that each set in any one of the collections is in the σ -algebra of any other collection. Let $\mathcal{S}_i = \sigma(\mathcal{B}_i)$ for $i \in \{1, 2, 3\}$

1. Clearly $\mathcal{B}_2 \subseteq \mathcal{B}_1$ and $\mathcal{B}_3 \subseteq \mathcal{B}_1$ so $\mathcal{S}_2 \subseteq \mathcal{S}_1$ and $\mathcal{S}_3 \subseteq \mathcal{S}_1$.
2. If $a, b \in \mathbb{R}$ with $a \leq b$ then $[a, b] = \bigcap_{n=1}^{\infty} (a - \frac{1}{n}, b]$ and $(a, b) = \bigcup_{n=1}^{\infty} (a, b - \frac{1}{n}]$, so $[a, b], (a, b) \in \mathcal{S}_2$. Also $[a, b) = \bigcup_{n=1}^{\infty} [a, b - \frac{1}{n}]$ so $[a, b) \in \mathcal{S}_2$. Thus all bounded intervals are in \mathcal{S}_2 . Next, $[a, \infty) = \bigcup_{n=1}^{\infty} [a, a + n)$, $(-\infty, a] = \bigcap_{n=1}^{\infty} (a - n, a]$, and $(-\infty, a) = \bigcup_{n=1}^{\infty} (a - n, a)$, so each of these intervals is in \mathcal{S}_2 . Of course $\mathbb{R} \in \mathcal{S}_2$, so we now have that $I \in \mathcal{S}_2$ for every interval I . Thus $\mathcal{S}_1 \subseteq \mathcal{S}_2$, and so from (a), $\mathcal{S}_2 = \mathcal{S}_1$.
3. If $a, b \in \mathbb{R}$ with $a < b$ then $(a, b] = (-\infty, b] - (-\infty, a]$ so $(a, b] \in \mathcal{S}_3$. Hence $\mathcal{S}_2 \subseteq \mathcal{S}_3$. But then from (a) and (b) it follows that $\mathcal{S}_3 = \mathcal{S}_1$.

Since the Euclidean topology has a countable base, \mathcal{R} is countably generated. In fact each collection of intervals above, but with endpoints restricted to \mathbb{Q} , generates \mathcal{R} . Moreover, \mathcal{R} can also be constructed from σ -algebras that are generated by [countable partitions](#). First recall that for $n \in \mathbb{N}$, the set of dyadic rationals (or *binary rationals*) of rank n or less is $\mathbb{D}_n = \{j/2^n : j \in \mathbb{Z}\}$. Note that \mathbb{D}_n is countable and $\mathbb{D}_n \subseteq \mathbb{D}_{n+1}$ for $n \in \mathbb{N}$. Moreover, the set $\mathbb{D} = \bigcup_{n \in \mathbb{N}} \mathbb{D}_n$ of *all* dyadic rationals is dense in \mathbb{R} . The dyadic rationals are often useful in various applications because \mathbb{D}_n has the natural ordered enumeration $j \mapsto j/2^n$ for each $n \in \mathbb{N}$. Now let

$$\mathcal{D}_n = \{(j/2^n, (j+1)/2^n] : j \in \mathbb{Z}\}, \quad n \in \mathbb{N} \quad (1.11.11)$$

Then \mathcal{D}_n is a countable partition of \mathbb{R} into nonempty intervals of equal size $1/2^n$, so $\mathcal{E}_n = \sigma(\mathcal{D}_n)$ consists of unions of sets in \mathcal{D}_n as described [above](#). Every set \mathcal{D}_n is the union of two sets in \mathcal{D}_{n+1} so clearly $\mathcal{E}_n \subseteq \mathcal{E}_{n+1}$ for $n \in \mathbb{N}$. Finally, the Borel σ -algebra on \mathbb{R} is $\mathcal{R} = \sigma(\bigcup_{n=0}^{\infty} \mathcal{E}_n) = \sigma(\bigcup_{n=0}^{\infty} \mathcal{D}_n)$. This construction turns out to be useful in a number of settings.

For $n \in \{2, 3, \dots\}$, the Euclidean topology on \mathbb{R}^n is the n -fold product topology formed from the Euclidean topology on \mathbb{R} . So the Borel σ -algebra \mathcal{R}^n is also the n -fold power σ -algebra formed from \mathcal{R} . Finally, \mathcal{R}^n can be generated by n -fold products of sets in any of the three collections in the [previous theorem](#).

Space of Real Functions

Suppose that (S, \mathcal{S}) is a measurable space. From our general discussion of functions, recall that the usual arithmetic operations on functions from S into \mathbb{R} are defined pointwise.

If $f : S \rightarrow \mathbb{R}$ and $g : S \rightarrow \mathbb{R}$ are measurable and $a \in \mathbb{R}$, then each of the following functions from S into \mathbb{R} is also measurable:

1. $f + g$
2. $f - g$
3. fg
4. af

Proof

These results follow from the fact that the arithmetic operators are continuous, and hence measurable. That is, $(x, y) \mapsto x + y$, $(x, y) \mapsto x - y$, and $(x, y) \mapsto xy$ are continuous as functions from \mathbb{R}^2 into \mathbb{R} . Thus, if $f, g : S \rightarrow \mathbb{R}$ are measurable, then $(f, g) : S \rightarrow \mathbb{R}^2$ is measurable by the [result above](#). Then, $f + g$, $f - g$, fg are the compositions, respectively, of $+$, $-$, \cdot with (f, g) . Of course, (d) is a simple corollary of (c).

Similarly, if $f : S \rightarrow \mathbb{R} \setminus \{0\}$ is measurable, then so is $1/f$. Recall that the set of functions from S into \mathbb{R} is a vector space, under the pointwise definitions of addition and scalar multiplication. But once again, we usually want to restrict our attention to *measurable* functions. Thus, it's nice to know that the measurable functions from S into \mathbb{R} also form a vector space. This follows immediately from the *closure properties* (a) and (d) of the previous theorem. Of particular importance in probability and stochastic processes is the vector space of bounded, measurable functions $f : S \rightarrow \mathbb{R}$, with the supremum norm

$$\|f\| = \sup \{|f(x)| : x \in S\} \quad (1.11.12)$$

The *elementary functions* that we encounter in calculus and other areas of applied mathematics are functions from subsets of \mathbb{R} into \mathbb{R} . The elementary functions include algebraic functions (which in turn include the polynomial and rational functions), the usual transcendental functions (exponential, logarithm, trigonometric), and the usual functions constructed from these by composition, the arithmetic operations, and by piecing together. As we might hope, all of the elementary functions are measurable.

1.12: Special Set Structures

There are several other types of algebraic set structures that are weaker than σ -algebras. These are not particularly important in themselves, but are important for constructing σ -algebras and the measures on these σ -algebras. You may want to skip this section if you are not interested in questions of existence and uniqueness of positive measures.

Basic Theory

Definitions

Throughout this section, we assume that S is a set and \mathcal{S} is a nonempty collection of subsets of S . Here are the main definitions we will need.

\mathcal{S} is a π -system if \mathcal{S} is closed under finite intersections: if $A, B \in \mathcal{S}$ then $A \cap B \in \mathcal{S}$.

Closure under intersection is clearly a very simple property, but π systems turn out to be useful enough to deserve a name.

\mathcal{S} is a λ -system if it is closed under complements and countable *disjoint* unions.

1. If $A \in \mathcal{S}$ then $A^c \in \mathcal{S}$.
2. If $A_i \in \mathcal{S}$ for i in a countable index set I and $A_i \cap A_j = \emptyset$ for $i \neq j$ then $\bigcup_{i \in I} A_i \in \mathcal{S}$.

\mathcal{S} is a *semi-algebra* if it is closed under intersection and if complements can be written as finite, disjoint unions:

1. If $A, B \in \mathcal{S}$ then $A \cap B \in \mathcal{S}$.
2. If $A \in \mathcal{S}$ then there exists a finite, disjoint collection $\{B_i : i \in I\} \subseteq \mathcal{S}$ such that $A^c = \bigcup_{i \in I} B_i$.

For our final structure, recall that a sequence (A_1, A_2, \dots) of subsets of S is *increasing* if $A_n \subseteq A_{n+1}$ for all $n \in \mathbb{N}_+$. The sequence is *decreasing* if $A_{n+1} \subseteq A_n$ for all $n \in \mathbb{N}_+$. Of course, these are the standard meanings of *increasing* and *decreasing* relative to the ordinary order \leq on \mathbb{N}_+ and the subset partial order \subseteq on $\mathcal{P}(S)$.

\mathcal{S} is a *monotone class* if it is closed under increasing unions and decreasing intersections:

1. If (A_1, A_2, \dots) is an increasing sequence of sets in \mathcal{S} then $\bigcup_{n=1}^{\infty} A_n \in \mathcal{S}$.
2. If (A_1, A_2, \dots) is a decreasing sequence of sets in \mathcal{S} then $\bigcap_{n=1}^{\infty} A_n \in \mathcal{S}$.

If (A_1, A_2, \dots) is an increasing sequence of sets then we sometimes write $\bigcup_{n=1}^{\infty} A_n = \lim_{n \rightarrow \infty} A_n$. Similarly, if (A_1, A_2, \dots) is a decreasing sequence of sets we sometimes write $\bigcap_{n=1}^{\infty} A_n = \lim_{n \rightarrow \infty} A_n$. The reason for this notation will become clear in the section on Convergence in the chapter on Probability Spaces. With this notation, a monotone class \mathcal{S} is defined by the condition that if (A_1, A_2, \dots) is an increasing or decreasing sequence of sets in \mathcal{S} then $\lim_{n \rightarrow \infty} A_n \in \mathcal{S}$.

Basic Theorems

Our most important set structure, the σ -algebra, has all of the properties in the definitions above.

If \mathcal{S} is a σ -algebra then \mathcal{S} is a π -system, a λ -system, a semi-algebra, and a monotone class.

If \mathcal{S} is a λ -system then $S \in \mathcal{S}$ and $\emptyset \in \mathcal{S}$.

Proof

The proof is just like the one for an algebra. There exists $A \in \mathcal{S}$ since \mathcal{S} is non-empty. Hence $A^c \in \mathcal{S}$ and so $S = A \cup A^c \in \mathcal{S}$. Finally $\emptyset = S^c \in \mathcal{S}$.

Any type of algebraic structure on subsets of S that is defined purely in terms of *closure properties* will be preserved under intersection. That is, we will have results that are analogous to how σ -algebras are generated from more basic sets, with completely straightforward and analogous proofs. In the following two theorems, the term *system* could mean π -system, λ -system, or monotone class of subsets of S .

If \mathcal{S}_i is a system for each i in an index set I and $\bigcap_{i \in I} \mathcal{S}_i$ is nonempty, then $\bigcap_{i \in I} \mathcal{S}_i$ is a system of the same type.

The condition that $\bigcap_{i \in I} \mathcal{S}_i$ be nonempty is unnecessary for a λ -system, by the [result above](#). Now suppose that \mathcal{B} is a nonempty collection of subsets of S , thought of as basic sets of some sort. Then the system generated by \mathcal{B} is the intersection of all systems that contain \mathcal{B} .

The system \mathcal{S} generated by \mathcal{B} is the smallest system containing \mathcal{B} , and is characterized by the following properties:

1. $\mathcal{B} \subseteq \mathcal{S}$.
2. If \mathcal{T} is a system and $\mathcal{B} \subseteq \mathcal{T}$ then $\mathcal{S} \subseteq \mathcal{T}$.

Note however, that the previous two results do not apply to semi-algebras, because the semi-algebra is not defined purely in terms of closure properties (the condition on A^c is not a closure property).

If \mathcal{S} is a monotone class and an algebra, then \mathcal{S} is a σ -algebra.

Proof

All that is needed is to prove closure under countable unions. Thus, suppose that $A_i \in \mathcal{S}$ for $i \in \mathbb{N}_+$. Then $B_n = \bigcup_{i=1}^n A_i \in \mathcal{S}$ since \mathcal{S} is an algebra. The sequence (B_1, B_2, \dots) is increasing, so $\bigcup_{n=1}^{\infty} B_n \in \mathcal{S}$, since \mathcal{S} is a monotone class. But $\bigcup_{n=1}^{\infty} B_n = \bigcup_{i=1}^{\infty} A_i$.

By definition, a semi-algebra is a π -system. More importantly, a semi-algebra can be used to construct an algebra.

Suppose that \mathcal{S} is a semi-algebra of subsets of S . Then the collection \mathcal{S}^* of finite, disjoint unions of sets in \mathcal{S} is an algebra.

Proof

Suppose that $A, B \in \mathcal{S}^*$. Then there exist finite, disjoint collections $\{A_i : i \in I\} \subseteq \mathcal{S}$ and $\{B_j : j \in J\} \subseteq \mathcal{S}$ such that $A = \bigcup_{i \in I} A_i$ and $B = \bigcup_{j \in J} B_j$. Hence

$$A \cap B = \bigcup_{(i,j) \in I \times J} (A_i \cap B_j) \quad (1.12.1)$$

But $\{A_i \cap B_j : (i,j) \in I \times J\}$ is a finite, disjoint collection of sets in \mathcal{S} , so $A \cap B \in \mathcal{S}^*$. Suppose $A \in \mathcal{S}^*$, so that there exists a finite, disjoint collection $\{A_i : i \in I\}$ such that $A = \bigcup_{i \in I} A_i$. Then $A^c = \bigcap_{i \in I} A_i^c$. But $A_i^c \in \mathcal{S}^*$ by definition of semi-algebra, and we just showed that \mathcal{S}^* is closed under finite intersections, so $A^c \in \mathcal{S}^*$.

We will say that our nonempty collection \mathcal{S} is *closed under proper set difference* if $A, B \in \mathcal{S}$ and $A \subseteq B$ implies $B \setminus A \in \mathcal{S}$. The following theorem gives the basic relationship between λ -systems and monotone classes.

Suppose that \mathcal{S} is a nonempty collection of subsets of S .

1. If \mathcal{S} is a λ -system then \mathcal{S} is a monotone class and is closed under proper set difference.
2. If \mathcal{S} is a monotone class, is closed under proper set difference, and contains S , then \mathcal{S} is a λ -system.

Proof

1. Suppose that \mathcal{S} is a λ -system. Suppose that $A, B \in \mathcal{S}$ and $A \subseteq B$. Then $B^c \in \mathcal{S}$, and A and B^c are disjoint, so $A \cup B^c \in \mathcal{S}$. But then $(A \cup B^c)^c = B \cap A^c = B \setminus A \in \mathcal{S}$. Hence \mathcal{S} is closed under proper set difference. Next suppose that (A_1, A_2, \dots) is an increasing sequence of sets in \mathcal{S} . Let $B_1 = A_1$ and $B_n = A_n \setminus A_{n-1}$ for $n \in \{2, 3, \dots\}$. Then $B_i \in \mathcal{S}$ for each $i \in \mathbb{N}_+$. But the sequence (B_1, B_2, \dots) is disjoint and has the same union as (A_1, A_2, \dots) . Hence $\bigcup_{i=1}^{\infty} A_i = \bigcup_{i=1}^{\infty} B_i \in \mathcal{S}$. Finally, suppose that (A_1, A_2, \dots) is a decreasing sequence of sets in \mathcal{S} . Then $A_i^c \in \mathcal{S}$ for each $i \in \mathbb{N}_+$ and (A_1^c, A_2^c, \dots) is increasing. Hence $\bigcup_{i=1}^{\infty} A_i^c \in \mathcal{S}$ and therefore $(\bigcup_{i=1}^{\infty} A_i^c)^c = \bigcap_{i=1}^{\infty} A_i \in \mathcal{S}$.
2. Suppose that \mathcal{S} is a monotone class, is closed under proper set difference, and $S \in \mathcal{S}$. If $A \in \mathcal{S}$ then trivially $A \subseteq S$ so $A^c = S \setminus A \in \mathcal{S}$. Next, suppose that $A, B \in \mathcal{S}$ are disjoint. Then $A^c \in \mathcal{S}$ and $B \subseteq A^c$, so $A^c \setminus B = A^c \cap B^c \in \mathcal{S}$. Hence $A \cup B = (A^c \cap B^c)^c \in \mathcal{S}$. Finally, suppose that (A_1, A_2, \dots) is a disjoint sequence of sets in \mathcal{S} . We just showed that \mathcal{S} is closed under finite, disjoint unions, so $B_n = \bigcup_{i=1}^n A_i \in \mathcal{S}$. But the sequence (B_1, B_2, \dots) is increasing, and hence $\bigcup_{n=1}^{\infty} B_n = \bigcup_{i=1}^{\infty} A_i \in \mathcal{S}$.

The following theorem is known as the *monotone class theorem*, and is due to the mathematician Paul Halmos.

Suppose that \mathcal{A} is an algebra, \mathcal{M} is a monotone class, and $\mathcal{A} \subseteq \mathcal{M}$. Then $\sigma(\mathcal{A}) \subseteq \mathcal{M}$.

Proof

First let $m(\mathcal{A})$ denote the monotone class generated by \mathcal{A} , as defined [above](#). The outline of the proof is to show that $m(\mathcal{A})$ is an algebra, so that by [\(9\)](#), $m(\mathcal{A})$ is a σ -algebra. It then follows that $\sigma(\mathcal{A}) \subseteq m(\mathcal{A}) \subseteq \mathcal{M}$. To show that $m(\mathcal{A})$ is an algebra, we first show that it is closed under complements and then under simple union.

Since $m(\mathcal{A})$ is a monotone class, the collection $m^*(\mathcal{A}) = \{A \subseteq S : A^c \in m(\mathcal{A})\}$ is also a monotone class. Moreover, $\mathcal{A} \subseteq m^*(\mathcal{A})$ so it follows that $m(\mathcal{A}) \subseteq m^*(\mathcal{A})$. Hence if $A \in m(\mathcal{A})$ then $A \in m^*(\mathcal{A})$ so $A^c \in m(\mathcal{A})$. Thus $m(\mathcal{A})$ is closed under complements.

Let $\mathcal{M}_1 = \{A \subseteq S : A \cup B \in m(\mathcal{A}) \text{ for all } B \in \mathcal{A}\}$. Then \mathcal{M}_1 is a monotone class and $\mathcal{A} \subseteq \mathcal{M}_1$ so $m(\mathcal{A}) \subseteq \mathcal{M}_1$. Next let $\mathcal{M}_2 = \{A \subseteq S : A \cup B \in m(\mathcal{A}) \text{ for all } B \in m(\mathcal{A})\}$. Then \mathcal{M}_2 is also a monotone class. Let $A \in \mathcal{A}$. If $B \in m(\mathcal{A})$ then $B \in \mathcal{M}_1$ and hence $A \cup B \in m(\mathcal{A})$. Hence $A \in \mathcal{M}_2$. Thus we have $\mathcal{A} \subseteq \mathcal{M}_2$, so $m(\mathcal{A}) \subseteq \mathcal{M}_2$. Finally, let $A, B \in m(\mathcal{A})$. Then $A \in \mathcal{M}_2$ so $A \cup B \in m(\mathcal{A})$ and therefore $m(\mathcal{A})$ is closed under simple union.

As noted in [\(5\)](#), a σ -algebra is both a π -system and a λ -system. The converse is also true, and is one of the main reasons for studying these structures.

If \mathcal{S} is a π -system and a λ -system then \mathcal{S} is a σ -algebra.

Proof

$S \in \mathcal{S}$, and if $A \in \mathcal{S}$ then $A^c \in \mathcal{S}$ by definition of a λ -system. Thus, all that is left is to show closure under countable unions. Thus, suppose that (A_1, A_2, \dots) is a sequence of sets in \mathcal{S} . Then $A_i^c \in \mathcal{S}$ for each $i \in \mathbb{N}_+$. Since \mathcal{S} is also a π -system, it follows that for each $n \in \mathbb{N}_+$, $B_n = A_n \cap A_1^c \cap \dots \cap A_{n-1}^c \in \mathcal{S}$ (by convention $B_1 = A_1$). But the sequence (B_1, B_2, \dots) is disjoint and has the same union as (A_1, A_2, \dots) . Hence $\bigcup_{i=1}^{\infty} A_i = \bigcup_{i=1}^{\infty} B_i \in \mathcal{S}$.

The importance of π -systems and λ -systems stems in part from Dynkin's π - λ theorem given next. It's named for the mathematician Eugene Dynkin.

Suppose that \mathcal{A} is a π -system of subsets of S , \mathcal{B} is a λ -system of subsets of S , and $\mathcal{A} \subseteq \mathcal{B}$. Then $\sigma(\mathcal{A}) \subseteq \mathcal{B}$.

Proof

Let \mathcal{L} denote the λ -system generated by \mathcal{A} . Then of course $\mathcal{A} \subseteq \mathcal{L} \subseteq \mathcal{B}$. For $A \in \mathcal{L}$, let

$$\mathcal{L}_A = \{B \subseteq S : B \cap A \in \mathcal{L}\} \quad (1.12.2)$$

We will show that \mathcal{L}_A is a λ -system. Note that $S \cap A = A \in \mathcal{L}$ and therefore $S \in \mathcal{L}_A$. Next, suppose that $B_1, B_2 \in \mathcal{L}_A$ and that $B_1 \subseteq B_2$. Then $B_1 \cap A \in \mathcal{L}$ and $B_2 \cap A \in \mathcal{L}$ and $B_1 \cap A \subseteq B_2 \cap A$. Hence $(B_2 \setminus B_1) \cap A = (B_2 \cap A) \setminus (B_1 \cap A) \in \mathcal{L}$. Hence $B_2 \setminus B_1 \in \mathcal{L}_A$. Finally, suppose that $\{B_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{L}_A . Then $B_i \cap A \in \mathcal{L}$ for each $i \in I$, and $\{B_i \cap A : i \in I\}$ is also a disjoint collection. Therefore, $\bigcup_{i \in I} (B_i \cap A) = (\bigcup_{i \in I} B_i) \cap A \in \mathcal{L}$. Hence $\bigcup_{i \in I} B_i \in \mathcal{L}_A$.

Next fix $A \in \mathcal{A}$. If $B \in \mathcal{A}$ then $A \cap B \in \mathcal{A}$, so $A \cap B \in \mathcal{L}$ and hence $B \in \mathcal{L}_A$. But \mathcal{L} is the smallest λ -system containing \mathcal{A} so we have shown that $\mathcal{L} \subseteq \mathcal{L}_A$ for every $A \in \mathcal{A}$. Now fix $B \in \mathcal{L}$. If $A \in \mathcal{A}$ then $B \in \mathcal{L}_A$ so $A \cap B \in \mathcal{L}$ and therefore $A \in \mathcal{L}_B$. Again, \mathcal{L} is the smallest λ -system containing \mathcal{A} so we have now shown that $\mathcal{L} \subseteq \mathcal{L}_B$ for every $B \in \mathcal{L}$. Finally, let $B, C \in \mathcal{L}$. Then $C \in \mathcal{L}_B$ and hence $B \cap C \in \mathcal{L}$. It now follows that \mathcal{L} is a π -system, as well as a λ -system, and therefore by the [theorem above](#), \mathcal{L} is a sigma-algebra. But $\mathcal{A} \subseteq \mathcal{L}$ and hence $\sigma(\mathcal{A}) \subseteq \mathcal{L}$.

Examples and Special Cases

Suppose that S is a set and \mathcal{A} is a finite partition of S . Then $\mathcal{S} = \{\emptyset\} \cup \mathcal{A}$ is a semi-algebra of subsets of S .

Proof

If $A, B \in \mathcal{A}$ then $A \cap B = \emptyset \in \mathcal{S}$. If $A \in \mathcal{S}$ then $A^c = \bigcup \{B \in \mathcal{A} : B \neq A\}$

Euclidean Spaces

The following example is particularly important because it will be used to construct positive measures on \mathbb{R} . Let

$$\mathcal{B} = \{(a, b] : a, b \in \mathbb{R}, a < b\} \cup \{(-\infty, b] : b \in \mathbb{R}\} \cup \{(a, \infty) : a \in \mathbb{R}\} \quad (1.12.3)$$

\mathcal{B} is a semi-algebra of subsets of \mathbb{R} .

Proof

Note that the intersection of two intervals of the type in \mathcal{B} is another interval of this type. The complement of an interval of this type is either another interval of this type or the union of two disjoint intervals of this type.

It follows from the [theorem above](#) that the collection \mathcal{A} of finite disjoint unions of intervals in \mathcal{B} is an algebra. Recall also that $\sigma(\mathcal{B}) = \sigma(\mathcal{A})$ is the Borel σ -algebra of \mathbb{R} , named for Émile Borel. We can generalize all of this to \mathbb{R}^n for $n \in \mathbb{N}_+$

The collection $\mathcal{B}_n = \{\prod_{i=1}^n A_i : A_i \in \mathcal{B} \text{ for each } i \in \{1, 2, \dots, n\}\}$ is a semi-algebra of subsets of \mathbb{R}^n .

Recall also that $\sigma(\mathcal{B}_n)$ is the σ -algebra of Borel sets of \mathbb{R}^n .

Product Spaces

The examples in this discussion are important for constructing positive measures on product spaces.

Suppose that \mathcal{S} is a semi-algebra of subsets of a set S and that \mathcal{T} is a semi-algebra of subsets of a set T . Then

$$\mathcal{U} = \{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\} \quad (1.12.4)$$

is a semi-algebra of subsets of $S \times T$.

Proof

1. Suppose that $A \times B, C \times D \in \mathcal{U}$, so that $A, C \in \mathcal{S}$ and $B, D \in \mathcal{T}$. Recall that $(A \times B) \cap (C \times D) = (A \cap C) \times (B \cap D)$. But $A \cap C \in \mathcal{S}$ and $B \cap D \in \mathcal{T}$ so $(A \times B) \cap (C \times D) \in \mathcal{U}$.
2. Suppose that $A \times B \in \mathcal{U}$ so that $A \in \mathcal{S}$ and $B \in \mathcal{T}$. Then

$$(A \times B)^c = (A^c \times B) \cup (A \times B^c) \cup (A^c \times B^c) \quad (1.12.5)$$

There exists a finite, disjoint collection $\{A_i : i \in I\}$ of sets in \mathcal{S} and a finite, disjoint collection $\{B_j : j \in J\}$ of sets in \mathcal{T} such that $A^c = \bigcup_{i \in I} A_i$ and $B^c = \bigcup_{j \in J} B_j$. Hence

$$(A \times B)^c = \left[\bigcup_{i \in I} (A_i \times B) \right] \cup \left[\bigcup_{j \in J} (A \times B_j) \right] \cup \left[\bigcup_{i \in I} \bigcup_{j \in J} (A_i \times B_j) \right] \quad (1.12.6)$$

All of the product sets in this union are in \mathcal{U} and the product sets are disjoint.

This result extends in a completely straightforward way to a product of a finite number of sets.

Suppose that $n \in \mathbb{N}_+$ and that \mathcal{S}_i is a semi-algebra of subsets of a set S_i for $i \in \{1, 2, \dots, n\}$. Then

$$\mathcal{U} = \left\{ \prod_{i=1}^n A_i : A_i \in \mathcal{S}_i \text{ for all } i \in \{1, 2, \dots, n\} \right\} \quad (1.12.7)$$

is a semi-algebra of subsets of $\prod_{i=1}^n S_i$.

Note that the semi-algebra of products of intervals in \mathbb{R}^n described [above](#) is a special case of this result. For the product of an infinite sequence of sets, the result is bit more tricky.

Suppose that \mathcal{S}_i is a semi-algebra of subsets of a set S_i for $i \in \mathbb{N}_+$. Then

$$\mathcal{U} = \left\{ \prod_{i=1}^{\infty} A_i : A_i \in \mathcal{S}_i \text{ for all } i \in \mathbb{N}_+ \text{ and } A_i = S_i \text{ for all but finitely many } i \in \mathbb{N}_+ \right\} \quad (1.12.8)$$

is a semi-algebra of subsets of $\prod_{i=1}^n S_i$.

Proof

The proof is very much like the previous ones.

1. Suppose that $A = \prod_{i=1}^{\infty} A_i \in \mathcal{U}$ and $B = \prod_{i=1}^{\infty} B_i \in \mathcal{U}$, so that $A_i, B_i \in \mathcal{S}_i$ for $i \in \mathbb{N}_+$ and $A_i = S_i$ for all but finitely many $i \in \mathbb{N}_+$ and $B_i = S_i$ for all but finitely many $i \in \mathbb{N}_+$. Then $A \cap B = \prod_{i=1}^{\infty} (A_i \cap B_i)$. Also, $A_i \cap B_i \in \mathcal{S}_i$ for $i \in \mathbb{N}_+$ and $A_i \cap B_i = S_i$ for all but finitely many $i \in \mathbb{N}_+$. So $A \cap B \in \mathcal{U}$.
2. Suppose that $A = \prod_{i=1}^{\infty} A_i \in \mathcal{U}$, where $A_i \in \mathcal{S}_i$ for $i \in \mathbb{N}_+$ and $A_i = S_i$ for $i > n$, for some $n \in \mathbb{N}_+$. Then $A^c = \bigcup_{j=1}^n B_j$ where

$$B_j = A_1 \times \cdots \times A_{j-1} \times A_j^c \times S_{j+1} \times S_{j+2} \times \cdots, \quad j \in \{1, 2, \dots, n\} \quad (1.12.9)$$

Note that the product sets in this union are disjoint. But for each $j \in \{1, 2, \dots, n\}$ there exists a finite disjoint collection $\{C_{j,k} : k \in K_j\}$ such that $A_j^c = \bigcup_{k \in K_j} C_{j,k}$. Substituting and distributing then gives A^c as a finite, disjoint union of sets in \mathcal{U} .

Note that this result would not be true with $\mathcal{U} = \{\prod_{i=1}^{\infty} A_i : A_i \in \mathcal{S}_i \text{ for all } i \in \mathbb{N}_+\}$. In general, the complement of a set in \mathcal{U} cannot be written as a finite disjoint union of sets in \mathcal{U} .

CHAPTER OVERVIEW

2: Probability Spaces

The basic topics in this chapter are fundamental to probability theory, and should be accessible to new students of probability. We start with the paradigm of the random experiment and its mathematical model, the probability space. The main objects in this model are sample spaces, events, random variables, and probability measures. We also study several concepts of fundamental importance: conditional probability and independence.

The advanced topics can be skipped if you are a new student of probability, or can be studied later, as the need arises. These topics include the convergence of random variables, the measure-theoretic foundations of probability theory, and the existence and construction of probability measures and random processes.

2.1: Random Experiments

Experiments

Probability theory is based on the paradigm of a *random experiment*; that is, an experiment whose outcome cannot be predicted with certainty, before the experiment is run. In *classical* or *frequency-based* probability theory, we also assume that the experiment can be repeated indefinitely under essentially the same conditions. The repetitions can be *in time* (as when we toss a single coin over and over again) or *in space* (as when we toss a bunch of similar coins all at once). The repeatability assumption is important because the classical theory is concerned with the long-term behavior as the experiment is replicated. By contrast, *subjective* or *belief-based* probability theory is concerned with measures of belief about what will happen when we run the experiment. In this view, repeatability is a less crucial assumption. In any event, a complete description of a random experiment requires a careful definition of precisely what information about the experiment is being recorded, that is, a careful definition of what constitutes an *outcome*.

The term *parameter* refers to a non-random quantity in a model that, once chosen, remains constant. Many probability models of random experiments have one or more parameters that can be adjusted to fit the physical experiment being modeled.

The subjects of probability and statistics have an inverse relationship of sorts. In probability, we start with a completely specified mathematical model of a random experiment. Our goal is perform various computations that help us understand the random experiment, help us predict what will happen when we run the experiment. In statistics, by contrast, we start with an incompletely specified mathematical model (one or more parameters may be unknown, for example). We run the experiment to collect data, and then use the data to draw inferences about the unknown factors in the mathematical model.

Compound Experiments

Suppose that we have n experiments (E_1, E_2, \dots, E_n) . We can form a new, compound experiment by performing the n experiments in sequence, E_1 first, and then E_2 and so on, independently of one another. The term *independent* means, intuitively, that the outcome of one experiment has no influence over any of the other experiments. We will make the term mathematically precise later.

In particular, suppose that we have a basic experiment. A fixed number (or even an infinite number) of independent replications of the basic experiment is a new, compound experiment. Many experiments turn out to be compound experiments and moreover, as noted above, (classical) probability theory itself is based on the idea of replicating an experiment.

In particular, suppose that we have a simple experiment with two outcomes. Independent replications of this experiment are referred to as Bernoulli trials, named for Jacob Bernoulli. This is one of the simplest, but most important models in probability. More generally, suppose that we have a simple experiment with k possible outcomes. Independent replications of this experiment are referred to as multinomial trials.

Sometimes an experiment occurs in well-defined stages, but in a *dependent* way, in the sense that the outcome of a given stage is influenced by the outcomes of the previous stages.

Sampling Experiments

In most statistical studies, we start with a population of objects of interest. The objects may be people, memory chips, or acres of corn, for example. Usually there are one or more numerical measurements of interest to us—the height and weight of a person, the lifetime of a memory chip, the amount of rain, amount of fertilizer, and yield of an acre of corn.

Although our interest is in the entire population of objects, this set is usually too large and too amorphous to study. Instead, we collect a random sample of objects from the population and record the measurements of interest of for each object in the sample.

There are two basic types of sampling. If we sample *with replacement*, each item is replaced in the population before the next draw; thus, a single object may occur several times in the sample. If we sample *without replacement*, objects are not replaced in the population. The chapter on Finite Sampling Models explores a number of models based on sampling from a finite population.

Sampling with replacement can be thought of as a compound experiment, based on independent replications of the simple experiment of drawing a single object from the population and recording the measurements of interest. Conversely, a compound experiment that consists of n independent replications of a simple experiment can usually be thought of as a sampling experiment.

On the other hand, sampling without replacement is an experiment that consists of dependent stages, because the population changes with each draw.

Examples and Applications

Probability theory is often illustrated using simple devices from games of chance: coins, dice, card, spinners, urns with balls, and so forth. Examples based on such devices are pedagogically valuable because of their simplicity and conceptual clarity. On the other hand, it would be a terrible shame if you were to think that probability is *only* about gambling and games of chance. Rather, try to see problems involving coins, dice, etc. as metaphors for more complex and realistic problems.

Coins and Dice

In terms of probability, the important fact about a coin is simply that when tossed it lands on one side or the other. Coins in Western societies, dating to antiquity, usually have the head of a prominent person engraved on one side and something of lesser importance on the other. In non-Western societies, coins often did not have a head on either side, but did have distinct engravings on the two sides, one typically more important than the other. Nonetheless, *heads* and *tails* are the ubiquitous terms used in probability theory to distinguish the *front* or *obverse* side of the coin from the *back* or *reverse* side of the coin.

Figure 2.1.1: Obverse and reverse sides of a Roman coin, about 241 CE, from [Wikipedia](#)

Consider the *coin experiment* of tossing a coin n times and recording the score (1 for heads or 0 for tails) for each toss.

1. Identify a parameter of the experiment.
2. Interpret the experiment as a compound experiment.
3. Interpret the experiment as a sampling experiment.
4. Interpret the experiment as n Bernoulli trials.

Answer

1. The number of coins n is the parameter.
2. The experiment consists of n independent replications of the simple experiment of tossing the coin one time.
3. The experiment can be thought of as selecting a sample of size n with replacement from the population $\{0, 1\}$.
4. There are two outcomes on each toss and the tosses are independent.

In the simulation of the coin experiment, set $n = 5$. Run the simulation 100 times and observe the outcomes.

Dice are randomizing devices that, like coins, date to antiquity and come in a variety of sizes and shapes. Typically, the faces of a die have numbers or other symbols engraved on them. Again, the important fact is that when a die is thrown, a unique face is chosen (usually the upward face, but sometimes the downward one). For more on dice, see the introductory section in the chapter on Games of Chance.

Consider the *dice experiment* of throwing a k -sided die (with faces numbered 1 to k), n times and recording the scores for each throw.

1. Identify the parameters of the experiment.
2. Interpret the experiment as a compound experiment.
3. Interpret the experiment as a sampling experiment.
4. Identify the experiment as n multinomial trials.

Answer

1. The parameters are the number of dice n and the number of faces k .
2. The experiment consists of n independent replications of the simple experiment of throwing one die.
3. The experiment can be thought of as selecting a sample of size n with replacement from the population $\{1, 2, \dots, k\}$.
4. The same k outcomes occur for each die the throws are independent.

In reality, most dice are *Platonic solids* (named for Plato of course) with 4, 6, 8, 12, or 20 sides. The six-sided die is the *standard die*.

Figure 2.1.2: Blue Platonic dice

In the simulation of the dice experiment, set $n = 5$. Run the simulation 100 times and observe the outcomes.

In the *die-coin experiment*, a standard die is thrown and then a coin is tossed the number of times shown on the die. The sequence of coin scores is recorded (1 for heads and 0 for tails). Interpret the experiment as a compound experiment.

Answer

The first stage consists rolling the die and the second stage consists of tossing the coin. The stages are dependent because the number of tosses depends on the outcome of the die throw.

Note that this experiment can be obtained by *randomizing* the parameter n in the basic coin experiment in (1).

Run the simulation of the die-coin experiment 100 times and observe the outcomes.

In the *coin-die experiment*, a coin is tossed. If the coin lands heads, a red die is thrown and if the coin lands tails, a green die is thrown. The coin score (1 for heads and 0 for tails) and the die score are recorded. Interpret the experiment as a compound experiment.

Answer

The first stage consists of tossing the coin and the second stage consists of rolling the die. The stages are dependent because different dice (that may behave differently) are thrown, depending on the outcome of the coin toss.

Run the simulation of the coin-die experiment 100 times and observe the outcomes.

Cards

Playing cards, like coins and dice, date to antiquity. From the point of view of probability, the important fact is that a playing card encodes a number of properties or attributes on the front of the card that are hidden on the back of the card. (Later in this chapter, these properties will become random variables.) In particular, a standard *card deck* can be modeled by the Cartesian product set

$$D = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, j, q, k\} \times \{\clubsuit, \diamondsuit, \heartsuit, \spadesuit\} \quad (2.1.1)$$

where the first coordinate encodes the *denomination* or *kind* (ace, 2–10, jack, queen, king) and where the second coordinate encodes the *suit* (clubs, diamonds, hearts, spades). Sometimes we represent a card as a *string* rather than an ordered pair (for example $q\heartsuit$ rather than (q, \heartsuit) for the queen of hearts). Some other properties, derived from the two main ones, are *color* (diamonds and hearts are red, clubs and spades are black), *face* (jacks, queens, and kings have faces, the other cards do not), and *suit order* (from least to highest rank: $(\clubsuit, \diamondsuit, \heartsuit, \spadesuit)$).

Consider the card experiment that consists of dealing n cards from a standard deck (without replacement).

1. Identify a parameter of the experiment.
2. Interpret the experiment as a compound experiment.
3. Interpret the experiment as a sampling experiment.

Answer

1. The parameter is n , the number of cards dealt.
2. At each stage, we draw a card from a deck, but the deck changes from one draw to the next, so the stages are dependent.
3. The experiment is to select a sample of size n from the population D , without replacement.

In the simulation of the card experiment, set $n = 5$. Run the simulation 100 times and observe the outcomes.

The special case $n = 5$ is the *poker experiment* and the special case $n = 13$ is the *bridge experiment*.

Open each of the following to see depictions of card playing in some famous paintings.

2. The Cardsharps by Michelangelo Carravagio
3. The Card Players by Paul Cézanne
4. His Station and Four Aces by CM Coolidge
5. Waterloo by CM Coolidge

Urn Models

Urn models are often used in probability as simple metaphors for sampling from a finite population.

An urn contains m distinct balls, labeled from 1 to m . The experiment consists of selecting n balls from the urn, without replacement, and recording the sequence of ball numbers.

1. Identify the parameters of the experiment.
2. Interpret the experiment as a compound experiment.
3. Interpret the experiment as a sampling experiment.

Answer

1. The parameters are the number of balls m and the sample size n .
2. At each stage, we draw a ball from the urn, but the contents of the urn change from one draw to the next, so the stages are dependent
3. The experiment is to select a sample of size n from the balls in the urn (the population), without replacement.

Consider the basic urn model of the previous exercise. Suppose that r of the m balls are red and the remaining $m - r$ balls are green. Identify an additional parameter of the model. This experiment is a metaphor for sampling from a general *dichotomous* population

Answer

The parameters are the population size m , the sample size n , and the number of red balls r .

In the simulation of the urn experiment, set $m = 100$, $r = 40$, and $n = 25$. Run the experiment 100 times and observe the results.

An urn initially contains m balls; r are red and $m - r$ are green. A ball is selected from the urn and removed, and then replaced with k balls of the same color. The process is repeated. This is known as *Pólya's urn model*, named after George Pólya.

1. Identify the parameters of the experiment.
2. Interpret the case $k = 0$ as a sampling experiment.
3. Interpret the case $k = 1$ as a sampling experiment.

Answer

1. The parameters are the population size m , the initial number of red balls r , and the number new balls added k .
2. When $k = 0$, each ball drawn is removed and no new balls are added, so the experiment is to select a sample of size n from the urn, without replacement.
3. When $k = 1$, each ball drawn is replaced with another ball of the same color. So at least in terms of the colors of the balls, the experiment is equivalent to selecting a sample of size n from the urn, with replacement.

Open the image of the painting *Allegory of Fortune* by Dosso Dossi. Presumably the young man has chosen lottery tickets from an urn.

Buffon's Coin Experiment

Buffon's coin experiment consists of tossing a coin with radius $r \leq \frac{1}{2}$ on a floor covered with square tiles of side length 1. The coordinates of the center of the coin are recorded, relative to axes through the center of the square, parallel to the sides. The experiment is named for comte de Buffon.

1. Identify a parameter of the experiment
2. Interpret the experiment as a compound experiment.
3. Interpret the experiment as sampling experiment.

Answer

1. The parameter is the coin radius r .
2. The experiment can be thought of as selecting the coordinates of the coin center independently of one another.
3. The experiment is equivalent to selecting a sample of size 2 from the population $[-\frac{1}{2}, \frac{1}{2}]$, with replacement.

In the simulation of Buffon's coin experiment, set $r = 0.1$. Run the experiment 100 times and observe the outcomes.

Reliability

In the usual model of *structural reliability*, a system consists of n components, each of which is either *working* or *failed*. The states of the components are uncertain, and hence define a random experiment. The system as a whole is also either working or failed, depending on the states of the components and how the components are connected. For example, a *series system* works if and only if each component works, while a *parallel system* works if and only if at least one component works. More generally, a *k out of n system* works if at least k components work.

Consider the k out of n reliability model.

1. Identify two parameters.
2. What value of k gives a series system?
3. What value of k gives a parallel system?

Answer

1. The parameters are k and n
2. $k = n$ gives a series system.
3. $k = 1$ gives a parallel system.

The reliability model above is a *static* model. It can be extended to a *dynamic* model by assuming that each component is initially working, but has a random time until failure. The system as a whole would also have a random time until failure that would depend on the component failure times and the structure of the system.

Genetics

In ordinary sexual reproduction, the genetic material of a child is a random combination of the genetic material of the parents. Thus, the birth of a child is a random experiment with respect to outcomes such as eye color, hair type, and many other physical traits. We are often particularly interested in the random transmission of traits and the random transmission of genetic disorders.

For example, let's consider an overly simplified model of an *inherited trait* that has two possible states (*phenotypes*), say a pea plant whose pods are either green or yellow. The term *allele* refers to alternate forms of a particular gene, so we are assuming that there is a gene that determines pod color, with two alleles: g for green and y for yellow. A pea plant has two alleles for the trait (one from each parent), so the possible *genotypes* are

- gg , alleles for green pods from each parent.
- gy , an allele for green pods from one parent and an allele for yellow pods from the other (we usually cannot observe which parent contributed which allele).
- yy , alleles for yellow pods from each parent.

The genotypes gg and yy are called *homozygous* because the two alleles are the same, while the genotype gy is called *heterozygous* because the two alleles are different. Typically, one of the alleles of the inherited trait is *dominant* and the other *recessive*. Thus, for example, if g is the dominant allele for pod color, then a plant with genotype gg or gy has green pods, while a plant with genotype

yy has yellow pods. Genes are passed from parent to child in a random manner, so each new plant is a random experiment with respect to pod color.

Pod color in peas was actually one of the first examples of an inherited trait studied by Gregor Mendel, who is considered the father of modern genetics. Mendel also studied the color of the flowers (yellow or purple), the length of the stems (short or long), and the texture of the seeds (round or wrinkled).

For another example, the *ABO blood type* in humans is controlled by three alleles: *a*, *b*, and *o*. Thus, the possible genotypes are *aa*, *ab*, *ao*, *bb*, *bo* and *oo*. The alleles *a* and *b* are *co-dominant* and *o* is *recessive*. Thus there are four possible blood types (phenotypes):

- Type *A*: genotype *aa* or *ao*
- Type *B*: genotype *bb* or *bo*
- Type *AB*: genotype *ab*
- type *O*: genotype *oo*

Of course, blood may be typed in much more extensive ways than the simple *ABO* typing. The *RH* factor (positive or negative) is the most well-known example.

For our third example, consider a *sex-linked* hereditary disorder in humans. This is a disorder due to a defect on the *X chromosome* (one of the two chromosomes that determine gender). Suppose that *h* denotes the healthy allele and *d* the defective allele for the gene linked to the disorder. Women have two X chromosomes, and typically *d* is *recessive*. Thus, a woman with genotype *hh* is completely normal with respect to the condition; a woman with genotype *hd* does not have the disorder, but is a *carrier*, since she can pass the defective allele to her children; and a woman with genotype *dd* has the disorder. A man has only one X chromosome (his other sex chromosome, the *Y chromosome*, typically plays no role in the disorder). A man with genotype *h* is normal and a man with genotype *d* has the disorder. Examples of sex-linked hereditary disorders are *dichromatism*, the most common form of color-blindness, and *hemophilia*, a bleeding disorder. Again, genes are passed from parent to child in a random manner, so the birth of a child is a random experiment in terms of the disorder.

Point Processes

There are a number of important processes that generate “random points in time”. Often the random points are referred to as *arrivals*. Here are some specific examples:

- times that a piece of radioactive material emits elementary particles
- times that customers arrive at a store
- times that requests arrive at a web server
- failure times of a device

To formalize an experiment, we might record the number of arrivals during a specified interval of time or we might record the times of successive arrivals.

There are other processes that produce “random points in space”. For example,

- flaws in a piece of sheet metal
- errors in a string of symbols (in a computer program, for example)
- raisins in a cake
- misprints on a page
- stars in a region of space

Again, to formalize an experiment, we might record the number of points in a given region of space.

Statistical Experiments

In 1879, Albert Michelson constructed an experiment for measuring the speed of light with an interferometer. The velocity of light data set contains the results of 100 repetitions of Michelson's experiment. Explore the data set and explain, in a general way, the variability of the data.

Answer

The variability is due to measurement and other experimental errors beyond the control of Michelson.

In 1998, two students at the University of Alabama in Huntsville designed the following experiment: purchase a bag of M&Ms (of a specified advertised size) and record the counts for red, green, blue, orange, and yellow candies, and the net weight (in grams). Explore the M&M data set and explain, in a general way, the variability of the data.

Answer

The variability in weight is due to measurement error on the part of the students and to manufacturing errors on the part of the company. The variability in color counts is less clear and may be due to purposeful randomness on the part of the company.

In 1999, two researchers at Belmont University designed the following experiment: capture a cicada in the Middle Tennessee area, and record the body weight (in grams), the wing length, wing width, and body length (in millimeters), the gender, and the species type. The cicada data set contains the results of 104 repetitions of this experiment. Explore the cicada data and explain, in a general way, the variability of the data.

Answer

The variability in body measurements is due to differences in the three species, to all sorts of environmental factors, and to measurement errors by the researchers.

On June 6, 1761, James Short made 53 measurements of the parallax of the sun, based on the transit of Venus. Explore the Short data set and explain, in a general way, the variability of the data.

Answer

The variability is due to measurement and other experimental errors beyond the control of Short.

In 1954, two massive field trials were conducted in an attempt to determine the effectiveness of the new vaccine developed by Jonas Salk for the prevention of polio. In both trials, a *treatment group* of children were given the vaccine while a *control group* of children were not. The incidence of polio in each group was measured. Explore the polio field trial data set and explain, in a general way, the underlying random experiment.

Answer

The basic random experiment is to observe whether a given child, in the treatment group or control group, comes down with polio in a specified period of time. Presumably, a lower incidence of polio in the treatment group compared with the control group would be evidence that the vaccine was effective.

Each year from 1969 to 1972 a lottery was held in the US to determine who would be drafted for military service. Essentially, the lottery was a *ball and urn model* and became famous because many believed that the process was not sufficiently random. Explore the Vietnam draft lottery data set and speculate on how one might judge the degree of randomness.

Answer

This is a difficult problem, but presumably in a sufficiently random lottery, one would not expect to see dates in the same month clustered too closely together. Observing such clustering, then, would be evidence that the lottery was not random.

Deterministic Versus Probabilistic Models

One could argue that some of the examples discussed above are inherently *deterministic*. In tossing a coin, for example, if we know the initial conditions (involving position, velocity, rotation, etc.), the forces acting on the coin (gravity, air resistance, etc.), and the makeup of the coin (shape, mass density, center of mass, etc.), then the laws of physics should allow us to predict precisely how the coin will land. This is true in a technical, theoretical sense, but false in a very real sense. Coins, dice, and many more complicated and important systems are *chaotic* in the sense that the outcomes of interest depend in a very sensitive way on the initial conditions and other parameters. In such situations, it might well be impossible to ever know the initial conditions and forces accurately enough to use deterministic methods.

In the coin experiment, for example, even if we strip away most of the real world complexity, we are still left with an essentially random experiment. Joseph Keller in his article "[The Probability of Heads](#)" deterministically analyzed the toss of a coin under a number of ideal assumptions:

1. The coin is a perfect circle and has negligible thickness

2. The center of gravity of the coin is the geometric center.
3. The coin is initially heads up and is given an initial upward velocity u and angular velocity ω .
4. In flight, the coin rotates about a horizontal axis along a diameter of the coin.
5. In flight, the coin is governed only by the force of gravity. All other possible forces (air resistance or wind, for example) are neglected.
6. The coin does not bounce or roll after landing (as might be the case if it lands in sand or mud).

Of course, few of these ideal assumptions are valid for real coins tossed by humans. Let $t = u/g$ where g is the acceleration of gravity (in appropriate units). Note that the t just has units of time (in seconds) and hence is independent of how distance is measured. The scaled parameter t actually represents the time required for the coin to reach its maximum height.

Keller showed that the regions of the parameter space (t, ω) where the coin lands either heads up or tails up are separated by the curves

$$\omega = \left(2n \pm \frac{1}{2}\right) \frac{\pi}{2t}, \quad n \in \mathbb{N} \quad (2.1.2)$$

The parameter n is the total number of revolutions in the toss. A plot of some of these curves is given below. The largest region, in the lower left corner, corresponds to the event that the coin does not complete even one rotation, and so of course lands heads up, just as it started. The next region corresponds to one rotation, with the coin landing tails up. In general, the regions alternate between heads and tails.

Figure 2.1.3: Regions of heads and tails

The important point, of course, is that for even moderate values of t and ω , the curves are very close together, so that a small change in the initial conditions can easily shift the outcome from heads up to tails up or conversely. As noted in Keller's article, the probabilist and statistician Persi Diaconis determined experimentally that typical values of the initial conditions for a real coin toss are $t = \frac{1}{4}$ seconds and $\omega = 76\pi \approx 238.6$ radians per second. These values correspond to $n = 19$ revolutions in the toss. Of course, this parameter point is far beyond the region shown in our graph, in a region where the curves are exquisitely close together.

2.2: Events and Random Variables

The purpose of this section is to study two basic types of objects that form part of the model of a random experiment. If you are a new student of probability, just ignore the measure-theoretic terminology and skip the technical details.

Sample Spaces

The Set of Outcomes

Recall that in a random experiment, the outcome cannot be predicted with certainty, before the experiment is run. On the other hand:

We assume that we can identify a fixed set S that includes all possible outcomes of a random experiment. This set plays the role of the universal set when modeling the experiment.

For simple experiments, S may be precisely the set of possible outcomes. More often, for complex experiments, S is a mathematically convenient set that includes the possible outcomes and perhaps other elements as well. For example, if the experiment is to throw a standard die and record the score that occurs, we would let $S = \{1, 2, 3, 4, 5, 6\}$, the set of possible outcomes. On the other hand, if the experiment is to capture a cicada and measure its body weight (in milligrams), we might conveniently take $S = [0, \infty)$, even though most elements of this set are impossible (we hope!). The problem is that we may not know exactly the outcomes that are possible. Can a light bulb burn without failure for one thousand hours? For one thousand days? for one thousand years?

Often the outcome of a random experiment consists of one or more real measurements, and thus, the S consists of all possible measurement sequences, a subset of \mathbb{R}^n for some $n \in \mathbb{N}_+$. More generally, suppose that we have n experiments and that S_i is the set of outcomes for experiment $i \in \{1, 2, \dots, n\}$. Then the Cartesian product $S_1 \times S_2 \times \dots \times S_n$ is the natural set of outcomes for the compound experiment that consists of performing the n experiments in sequence. In particular, if we have a basic experiment with S as the set of outcomes, then S^n is the natural set of outcomes for the compound experiment that consists of n replications of the basic experiment. Similarly, if we have an infinite sequence of experiments and S_i is the set of outcomes for experiment $i \in \mathbb{N}_+$, then $S_1 \times S_2 \times \dots$ is the natural set of outcomes for the compound experiment that consists of performing the given experiments in sequence. In particular, the set of outcomes for the compound experiment that consists of indefinite replications of a basic experiment is $S^\infty = S \times S \times \dots$. This is an essential special case, because (classical) probability theory is based on the idea of replicating a given experiment.

Events

Consider again a random experiment with S as the set of outcomes. Certain subsets of S are referred to as *events*. Suppose that $A \subseteq S$ is a given event, and that the experiment is run, resulting in outcome $s \in S$.

1. If $s \in A$ then we say that A occurs.
2. If $s \notin A$ then we say that A does not occur.

Intuitively, you should think of an event as a meaningful *statement* about the experiment: every such statement translates into an event, namely the set of outcomes for which the statement is true. In particular, S itself is an event; by definition it *always* occurs. At the other extreme, the empty set \emptyset is also an event; by definition it *never* occurs.

For a note on terminology, recall that a *mathematical space* consists of a set together with other mathematical structures defined on the set. An example you may be familiar with is a *vector space*, which consists of a set (the vectors) together with the operations of addition and scalar multiplication. In probability theory, many authors use the term *sample space* for the set of outcomes of a random experiment, but here is the more careful definition:

The *sample space* of an experiment is (S, \mathcal{S}) where S is the set of outcomes and \mathcal{S} is the collection of events.

Details

Sometimes not every subset of S can be allowed as an event, but the collection of events \mathcal{S} is required to be a σ -algebra, so that the sample space (S, \mathcal{S}) is a measurable space. The axioms of a σ -algebra ensure that new sets that are constructed in a

reasonable way from given events, using the set operations, are themselves valid events. Most of the sample spaces that occur in elementary probability fall into two general categories.

1. *Discrete*: S is countable and $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S . In this case, the sample space (S, \mathcal{S}) is *discrete*.
2. *Euclidean*: S is a measurable subset of \mathbb{R}^n for some $n \in \mathbb{N}_+$ and \mathcal{S} is the collection of measurable subsets of S .

In (b), the measurable subsets of \mathbb{R}^n include all of the sets encountered in calculus and in standard applications of probability theory, and many more besides. Nonetheless, for technical reasons, certain very weird subsets must be excluded. Typically S is a set defined by a finite number of inequalities involving elementary functions.

The Algebra of Events

The standard algebra of sets leads to a grammar for discussing random experiments and allows us to construct new events from given events. In the following results, suppose that S is the set of outcomes of a random experiment, and that A and B are events.

$A \subseteq B$ if and only if the occurrence of A *implies* the occurrence of B .

Proof

Recall that \subseteq is the subset relation. So by definition, $A \subseteq B$ means that $s \in A$ implies $s \in B$.

$A \cup B$ is the event that occurs if and only if A occurs *or* B occurs.

Proof

Recall that $A \cup B$ is the *union* of A and B . So by definition, $s \in A \cup B$ if and only if $s \in A$ or $s \in B$.

$A \cap B$ is the event that occurs if and only if A occurs *and* B occurs.

Proof

Recall that $A \cap B$ is the *intersection* of A and B . So by definition, $s \in A \cap B$ if and only if $s \in A$ and $s \in B$.

A and B are disjoint if and only if they are *mutually exclusive*; they cannot both occur on the same run of the experiment.

Proof

By definition, A and B *disjoint* means that $A \cap B = \emptyset$.

A^c is the event that occurs if and only if A does *not* occur.

Proof

Recall that A^c is the *complement* of A , so $s \in A^c$ if and only if $s \notin A$.

$A \setminus B$ is the event that occurs if and only if A occurs *and* B does *not* occur.

Proof

Recall that $A \setminus B = A \cap B^c$. Hence $s \in A \setminus B$ if and only if $s \in A$ and $s \notin B$.

$(A \cap B^c) \cup (B \cap A^c)$ is the event that occurs if and only if *one but not both* of the given events occurs.

Proof

The events in the union are disjoint. So for s is in the given event if and only if either $s \in A$ and $s \notin B$, or $s \in B$ and $s \notin A$.

Recall that the event in (10) is the *symmetric difference* of A and B , and is sometimes denoted $A \Delta B$. This event corresponds to *exclusive or*, as opposed to the ordinary union $A \cup B$ which corresponds to *inclusive or*.

$(A \cap B) \cup (A^c \cap B^c)$ is the event that occurs if and only if *both or neither* of the given events occurs.

Proof

The events in the union are disjoint. Thus s is in the given event if and only if either $s \in A$ and $s \in B$, or $s \notin A$ and $s \notin B$.

In the Venn diagram app, observe the diagram of each of the 16 events that can be constructed from A and B .

Suppose now that $\mathcal{A} = \{A_i : i \in I\}$ is a collection of events for the random experiment, where I is a countable index set.

$\bigcup_{i \in I} A_i$ is the event that occurs if and only if *at least one* event in the collection occurs.

Proof

Note that $s \in \bigcup_{i \in I} A_i$ if and only if $s \in A_i$ for some $i \in I$.

$\bigcap_{i \in I} A_i$ is the event that occurs if and only if *every* event in the collection occurs:

Proof

Note that $s \in \bigcap_{i \in I} A_i$ if and only if $s \in A_i$ for every $i \in I$.

\mathcal{A} is a pairwise disjoint collection if and only if the events are *mutually exclusive*; at most one of the events could occur on a given run of the experiment.

Proof

By definition, $A_i \cap A_j = \emptyset$ for distinct $i, j \in I$.

Suppose now that (A_1, A_2, \dots) is an infinite sequence of events.

$\bigcup_{n=1}^{\infty} \bigcup_{i=n}^{\infty} A_i$ is the event that occurs if and only if *infinitely many* of the given events occur. This event is sometimes called the *limit superior* of (A_1, A_2, \dots) .

Proof

Note that s is in the given event if and only if for every $n \in \mathbb{N}_+$ there exists $i \in \mathbb{N}_+$ with $i \geq n$ such that $s \in A_i$. In turn this means that $s \in A_i$ for infinitely many $i \in I$.

$\bigcup_{n=1}^{\infty} \bigcap_{i=n}^{\infty} A_i$ is the event that occurs if and only if *all but finitely many* of the given events occur. This event is sometimes called the *limit inferior* of (A_1, A_2, \dots) .

Proof

Note that s is in the given event if and only if there exists $n \in \mathbb{N}_+$ such that $s \in A_i$ for every $i \in \mathbb{N}_+$ with $i \geq n$. In turn, this means that $s \in A_i$ for all but finitely many $i \in I$.

Limit superiors and inferiors are discussed in more detail in the section on convergence.

Random Variables

Intuitively, a *random variable* is a measurement of interest in the context of the experiment. Simple examples include the number of heads when a coin is tossed several times, the sum of the scores when a pair of dice are thrown, the lifetime of a device subject to random stress, the weight of a person chosen from a population. Many more examples are given below in the [exercises below](#). Mathematically, a random variable is a function defined on the set of outcomes.

A function X from S into a set T is a *random variable* for the experiment with values in T .

Details

The set T will also come with a σ -algebra \mathcal{T} of admissible subsets, so that (T, \mathcal{T}) is a measurable space, just like (S, \mathcal{S}) . The function X is required to be measurable, an assumption which ensures that meaningful statements involving X define events. In the discussion below, all subsets of T are assumed to be in \mathcal{T} .

Probability has its own notation, very different from other branches of mathematics. As a case in point, random variables, even though they are functions, are usually denoted by capital letters near the end of the alphabet. The use of a letter near the end of the alphabet is intended to emphasize the idea that the object is a *variable* in the context of the experiment. The use of a capital letter is intended to emphasize the fact that it is not an ordinary *algebraic* variable to which we can assign a specific value, but rather a

random variable whose value is indeterminate until we run the experiment. Specifically, when we run the experiment an outcome $s \in S$ occurs, and random variable X takes the value $X(s) \in T$.

Figure 2.2.1: A random variable as a function defined on the set of outcomes.

If $B \subseteq T$, we use the notation $\{X \in B\}$ for the inverse image $\{s \in S : X(s) \in B\}$, rather than $X^{-1}(B)$. Again, the notation is more natural since we think of X as a variable in the experiment. Think of $\{X \in B\}$ as a *statement* about X , which then translates into the event $\{s \in S : X(s) \in B\}$

Figure 2.2.2: The event $\{X \in B\}$ corresponding to $B \subseteq T$

Again, every statement about a random variable X with values in T translates into an inverse image of the form $\{X \in B\}$ for some $B \subseteq T$. So, for example, if $x \in T$ then $\{X = x\} = \{X \in \{x\}\} = \{s \in S : X(s) = x\}$. If X is a real-valued random variable and $a, b \in \mathbb{R}$ with $a < b$ then $\{a \leq X \leq b\} = \{X \in [a, b]\} = \{s \in S : a \leq X(s) \leq b\}$.

Suppose that X is a random variable taking values in T , and that $A, B \subseteq T$. Then

1. $\{X \in A \cup B\} = \{X \in A\} \cup \{X \in B\}$
2. $\{X \in A \cap B\} = \{X \in A\} \cap \{X \in B\}$
3. $\{X \in A \setminus B\} = \{X \in A\} \setminus \{X \in B\}$
4. $A \subseteq B \implies \{X \in A\} \subseteq \{X \in B\}$
5. If A and B are disjoint, then so are $\{X \in A\}$ and $\{X \in B\}$.

Proof

This is a restatement of the fact that inverse images of a function preserve the set operations; only the notation changes (and is simpler).

1. $s \in \{X \in A \cup B\}$ if and only if $X(s) \in A \cup B$ if and only if $X(s) \in A$ or $X(s) \in B$ if and only if $s \in \{X \in A\}$ or $s \in \{X \in B\}$ if and only if $s \in \{X \in A\} \cup \{X \in B\}$.
2. The proof is exactly the same as (a), with *and* replacing *or*.
3. The proof is also exactly the same as (a), with *but not* replacing *or*.
4. If $s \in \{X \in A\}$ then $X(s) \in A$ so $X(s) \in B$ and hence $s \in \{X \in B\}$.
5. This follows from part (b).

As with a general function, the result in part (a) holds for the union of a countable collection of subsets, and the result in part (b) holds for the intersection of a countable collection of subsets. No new ideas are involved; only the notation is more complicated.

Often, a random variable takes values in a subset T of \mathbb{R}^k for some $k \in \mathbb{N}_+$. We might express such a random variable as $\mathbf{X} = (X_1, X_2, \dots, X_k)$ where X_i is a real-valued random variable for each $i \in \{1, 2, \dots, k\}$. In this case, we usually refer to \mathbf{X} as a *random vector*, to emphasize its higher-dimensional character. A random variable can have an even more complicated structure. For example, if the experiment is to select n objects from a population and record various real measurements for each object, then the outcome of the experiment is a vector of vectors: $\mathbf{X} = (X_1, X_2, \dots, X_n)$ where X_i is the vector of measurements for the i th object. There are other possibilities; a random variable could be an infinite sequence, or could be set-valued. Specific examples are given in the computational exercises below. However, the important point is simply that a random variable is a function defined on the set of outcomes S .

The outcome of the experiment itself can be thought of as a random variable. Specifically, let $T = S$ and let X denote the identity function on S so that $X(s) = s$ for $s \in S$. Then trivially X is a random variable, and the events that can be defined in terms of X

are simply the original events of the experiment. That is, if A is an event then $\{X \in A\} = A$. Conversely, every random variable effectively defines a new random experiment.

In the general setting above, a random variable X defines a new random experiment with T as the new set of outcomes and subsets of T as the new collection of events.

Details

Technically, the σ -algebra \mathcal{T} would be the new collection of events.

In fact, often a random experiment is modeled by specifying the random variables of interest, in the language of the experiment. Then, a mathematical definition of the random variables specifies the sample space. A function (or transformation) of a random variable defines a new random variable.

Suppose that X is a random variable for the experiment with values in T and that g is a function from T into another set U . Then $Y = g(X)$ is a random variable with values in U .

Details

Technically, T and U both come with σ -algebras of admissible subsets \mathcal{T} and \mathcal{U} , respectively. The function g , just like the function X , is required to be measurable. This assumption ensures that $Y = g(X)$ is a measurable function from S into U , and hence is a valid random variable.

Note that, as functions, $g(X) = g \circ X$, the composition of g with X . But again, thinking of X and Y as *variables* in the context of the experiment, the notation $Y = g(X)$ is much more natural.

Indicator Variables

For an event A , the indicator function of A is called the *indicator variable* of A .

The value of this random variables tells us whether or not A has occurred:

$$\mathbf{1}_A = \begin{cases} 1, & A \text{ occurs} \\ 0, & A \text{ does not occur} \end{cases} \quad (2.2.1)$$

That is, as a function on S ,

$$\mathbf{1}_A(s) = \begin{cases} 1, & s \in A \\ 0, & s \notin A \end{cases} \quad (2.2.2)$$

If X is a random variable that takes values 0 and 1, then X is the indicator variable of the event $\{X = 1\}$.

Proof

Note that for $s \in S$, $X(s) = 1$ if $s \in \{X = 1\}$ and $X(s) = 0$ otherwise.

Recall also that the set algebra of events translates into the arithmetic algebra of indicator variables.

Suppose that A and B are events.

1. $\mathbf{1}_{A \cap B} = \mathbf{1}_A \mathbf{1}_B = \min \{\mathbf{1}_A, \mathbf{1}_B\}$
2. $\mathbf{1}_{A \cup B} = 1 - (1 - \mathbf{1}_A)(1 - \mathbf{1}_B) = \max \{\mathbf{1}_A, \mathbf{1}_B\}$
3. $\mathbf{1}_{B \setminus A} = \mathbf{1}_B (1 - \mathbf{1}_A)$
4. $\mathbf{1}_{A^c} = 1 - \mathbf{1}_A$
5. $A \subseteq B$ if and only if $\mathbf{1}_A \leq \mathbf{1}_B$

The results in part (a) extends to arbitrary intersections and the results in part (b) extends to arbitrary unions. If the event A has a complicated description, sometimes we use $\mathbf{1}(A)$ for the indicator variable rather than $\mathbf{1}_A$.

Examples and Applications

Recall that probability theory is often illustrated using simple devices from games of chance: coins, dice, cards, spinners, urns with balls, and so forth. Examples based on such devices are pedagogically valuable because of their simplicity and conceptual clarity. On the other hand, remember that probability is not only about gambling and games of chance. Rather, try to see problems involving coins, dice, etc. as metaphors for more complex and realistic problems.

Coins and Dice

The basic *coin experiment* consists of tossing a coin n times and recording the sequence of scores (X_1, X_2, \dots, X_n) (where 1 denotes heads and 0 denotes tails). This experiment is a generic example of n Bernoulli trials, named for Jacob Bernoulli.

Consider the coin experiment with $n = 4$, and Let Y denote the number of heads.

1. Give the set of outcomes S in list form.
2. Give the event $\{Y = k\}$ in list form for each $k \in \{0, 1, 2, 3, 4\}$.

Answer

To simplify the notation, we represent outcomes a *bit strings* rather than ordered sequences.

$$1. S = \{1111, 1110, 1101, 1011, 0111, 1100, 1010, 1001, 0110, 0101, 0011, 1000, 0100, 0010, 0001, 0000\}$$

$$\begin{aligned} 2. \quad \{Y = 0\} &= \{0000\} & (2.2.3) \\ \{Y = 1\} &= \{1000, 0100, 0010, 0001\} & (2.2.4) \\ \{Y = 2\} &= \{1100, 1010, 1001, 0110, 0101, 0011\} & (2.2.5) \\ \{Y = 3\} &= \{1110, 1101, 1011, 0111\} & (2.2.6) \\ \{Y = 4\} &= \{1111\} & (2.2.7) \end{aligned}$$

In the simulation of the coin experiment, set $n = 4$. Run the experiment 100 times and count the number of times that the event $\{Y = 2\}$ occurs.

Now consider the general coin experiment with the coin tossed n times, and let Y denote the number of heads.

1. Give the set of outcomes S in Cartesian product form, and give the cardinality of S .
2. Express Y as a function on S .
3. Find $\#\{Y = k\}$ (as a subset of S) for $k \in \{0, 1, \dots, n\}$

Answer

1. $S = \{0, 1\}^n$ and $\#(S) = 2^n$.
2. $Y(x_1, x_2, \dots, x_n) = x_1 + x_2 + \dots + x_n$. The set of possible values is $\{0, 1, \dots, n\}$
3. $\#\{Y = k\} = \binom{n}{k}$

The basic *dice experiment* consists of throwing n distinct k -sided dice (with faces numbered from 1 to k) and recording the sequence of scores (X_1, X_2, \dots, X_n) . This experiment is a generic example of n multinomial trials. The special case $k = 6$ corresponds to *standard dice*.

Consider the dice experiment with $n = 2$ standard dice. Let S denote the set of outcomes, A the event that the first die score is 1, and B the event that the sum of the scores is 7. Give each of the following events in the form indicated:

1. S in Cartesian product form
2. A in list form
3. B in list form
4. $A \cup B$ in list form
5. $A \cap B$ in list form
6. $A^c \cap B^c$ in predicate form

Answer

1. $S = \{1, 2, 3, 4, 5, 6\}^2$
2. $A = \{(1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (1, 6)\}$

3. $B = \{(1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1)\}$
4. $A \cup B = \{(1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1)\}$
5. $A \cap B = \{(1, 6)\}$
6. $A^c \cap B^c = \{(x, y) \in S : x + y \neq 7 \text{ and } x \neq 1\}$

In the simulation of the dice experiment, set $n = 2$. Run the experiment 100 times and count the number of times each event in the previous exercise occurs.

Consider the dice experiment with $n = 2$ standard dice, and let S denote the set of outcomes, Y the sum of the scores, U the minimum score, and V the maximum score.

1. Express Y as a function on S and give the set of possible values in list form.
2. Express U as a function on S and give the set of possible values in list form.
3. Express V as a function on the S and give the set of possible values in list form.
4. Give the set of possible values of (U, V) in predicate form

Answer

Note that $S = \{1, 2, 3, 4, 5, 6\}^2$. The following functions are defined on S .

1. $Y(x_1, x_2) = x_1 + x_2$. The set of values is $\{2, 3, \dots, 12\}$
2. $U(x_1, x_2) = \min\{x_1, x_2\}$. The set of values is $\{1, 2, \dots, 6\}$
3. $V(x_1, x_2) = \max\{x_1, x_2\}$. The set of values is $\{1, 2, \dots, 6\}$
4. $\{(u, v) \in \{1, 2, 3, 4, 5, 6\}^2 : u \leq v\}$

Consider again the dice experiment with $n = 2$ standard dice, and let S denote the set of outcomes, Y the sum of the scores, U the minimum score, and V the maximum score. Give each of the following as subsets of S , in list form.

1. $\{X_1 < 3, X_2 > 4\}$
2. $\{Y = 7\}$
3. $\{U = 2\}$
4. $\{V = 4\}$
5. $\{U = V\}$

Answer

1. $\{(1, 5), (2, 5), (1, 6), (2, 6)\}$
2. $\{(1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1)\}$
3. $\{(2, 2), (2, 3), (3, 2), (2, 4), (4, 2), (2, 5), (5, 2), (2, 6), (6, 2)\}$
4. $\{(4, 1), (1, 4), (2, 4), (4, 2), (4, 3), (3, 4), (4, 4)\}$
5. $\{(1, 1), (2, 2), (3, 3), (4, 4), (5, 5), (6, 6)\}$

In the dice experiment, set $n = 2$. Run the experiment 100 times. Count the number of times each event in the previous exercise occurred.

In the general dice experiment with n distinct k -sided dice, let Y denote the sum of the scores, U the minimum score, and V the maximum score.

1. Give the set of outcomes S and find $\#(S)$.
2. Express Y as a function on S , and give the set of possible values in list form.
3. Express U as a function on S , and give the set of possible values in list form.
4. Express V as a function on S , and give the set of possible values in list form.
5. Give the set of possible values of (U, V) in predicate form.

Answer

1. $S = \{1, 2, \dots, k\}^n$ and $\#(S) = k^n$
2. $Y(x_1, x_2, \dots, x_n) = x_1 + x_2 + \dots + x_n$. The set of possible values is $\{n, n+1, \dots, nk\}$
3. $U(x_1, x_2, \dots, x_n) = \min\{x_1, x_2, \dots, x_n\}$. The set of possible values is $\{1, 2, \dots, k\}$

4. $V(x_1, x_2, \dots, x_n) = \max\{x_1, x_2, \dots, x_n\}$. The set of possible values is $\{1, 2, \dots, k\}$
5. $\{(u, v) \in \{1, 2, \dots, k\}^2 : u \leq v\}$

The set of outcomes of a random experiment depends of course on what information is recorded. The following exercise is an illustration.

An experiment consists of throwing a pair of standard dice repeatedly until the sum of the two scores is either 5 or 7. Let A denote the event that the sum is 5 rather than 7 on the final throw. Experiments of this type arise in the casino game craps.

1. Suppose that the pair of scores on each throw is recorded. Define the set of outcomes of the experiment and describe A as a subset of this set.
2. Suppose that the pair of scores on the final throw is recorded. Define the set of outcomes of the experiment and describe A as a subset of this set.

Answer

Let $D_5 = \{(1, 4), (2, 3), (3, 2), (4, 1)\}$ $D_7 = \{(1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1)\}$ $D = D_5 \cup D_7$, and $C = D^c$

1. $S = D \cup (C \times D) \cup (C^2 \times D) \cup \dots$, $A = D_5 \cup (C \times D_5) \cup (C^2 \times D_5) \cup \dots$
2. $S = D$, $A = D_5$

Suppose that 3 standard dice are rolled and the sequence of scores (X_1, X_2, X_3) is recorded. A person pays \$1 to play. If some of the dice come up 6, then the player receives her \$1 back, plus \$1 for each 6. Otherwise she loses her \$1. Let W denote the person's net winnings. This is the game of chuck-a-luck and is treated in more detail in the chapter on Games of Chance.

1. Give the set of outcomes S in Cartesian product form.
2. Express W as a function on S and give the set of possible values in list form.

Answer

1. $S = \{1, 2, 3, 4, 5, 6\}^3$
2. $W(x_1, x_2, x_3) = \mathbf{1}(x_1 = 6) + \mathbf{1}(x_2 = 6) + \mathbf{1}(x_3 = 6) - \mathbf{1}(x_1 \neq 6, x_2 \neq 6, x_3 \neq 6)$. The set of possible values is $\{-1, 1, 2, 3\}$

Play the chuck-a-luck experiment a few times and see how you do.

In the *die-coin experiment*, a standard die is rolled and then a coin is tossed the number of times shown on the die. The sequence of coin scores \mathbf{X} is recorded (0 for tails, 1 for heads). Let N denote the die score and Y the number of heads.

1. Give the set of outcomes S in terms of Cartesian powers and find $\#(S)$.
2. Express N as a function on S and give the set of possible values in list form.
3. Express Y as a function on S and give the set of possible values in list form.
4. Give the event A that all tosses result in heads in list form.

Answer

1. $S = \bigcup_{n=1}^6 \{0, 1\}^n$, $\#(S) = 126$
2. $N(x_1, x_2, \dots, x_n) = n$ for $(x_1, x_2, \dots, x_n) \in S$. The set of values is $\{1, 2, 3, 4, 5, 6\}$
3. $Y(x_1, x_2, \dots, x_n) = \sum_{i=1}^n x_i$ for $(x_1, x_2, \dots, x_n) \in S$. The set of possible values is $\{0, 1, 2, 3, 4, 5, 6\}$
4. $A = \{1, 11, 111, 1111, 11111, 111111\}$

Run the simulation of the die-coin experiment 10 times. For each run, give the values of the random variables \mathbf{X} , N , and Y of the previous exercise. Count the number of times the event A occurs.

In the *coin-die experiment*, we have a coin and two distinct dice, say one red and one green. First the coin is tossed, and then if the result is heads the red die is thrown, while if the result is tails the green die is thrown. The coin score X and the score of the chosen die Y are recorded. Suppose now that the red die is a standard 6-sided die, and the green die a 4-sided die.

1. Give the set of outcomes S in list form.
2. Express X as a function on S .

- Express Y as a function on S .
- Give the event $\{Y \geq 3\}$ as a subset of S in list form.

Answer

- $\{(0, 1), (0, 2), (0, 3), (0, 4), (1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (1, 6)\}$
- $X(i, j) = i$ for $(i, j) \in S$
- $Y(i, j) = j$ for $(i, j) \in S$
- $\{(0, 3), (0, 4), (1, 3), (1, 4), (1, 5), (1, 6)\}$

Run the coin-die experiment 100 times, with various types of dice.

Sampling Models

Recall that many random experiments can be thought of as *sampling experiments*. For the general finite sampling model, we start with a population D with m (distinct) objects. We select a sample of n objects from the population. If the sampling is done in a random way, then we have a random experiment with the sample as the basic outcome. Thus, the set of outcomes of the experiment is literally the *set of samples*; this is the historical origin of the term *sample space*. There are four common types of sampling from a finite population, based on the criteria of *order* and *replacement*. Recall the following facts from the section on combinatorial structures:

Samples of size n chosen from a population with m elements.

- If the sampling is with replacement and with regard to order, then the set of samples is the Cartesian power D^n . The number of samples is m^n .
- If the sampling is without replacement and with regard to order, then the set of samples is the set of all *permutations* of size n from D . The number of samples is $m^{(n)} = m(m-1) \cdots [m-(n-1)]$.
- If the sampling is without replacement and without regard to order, then the set of samples is the set of all *combinations* (or *subsets*) of size n from D . The number of samples is $\binom{m}{n}$.
- If the sampling is with replacement and without regard to order, then the set of samples is the set of all *multisets* of size n from D . The number of samples is $\binom{m+n-1}{n}$.

If we sample with replacement, the sample size n can be any positive integer. If we sample without replacement, the sample size cannot exceed the population size, so we must have $n \in \{1, 2, \dots, m\}$.

The basic [coin and dice experiments](#) are examples of sampling *with* replacement. If we toss a coin n times and record the sequence of scores (where as usual, 0 denotes tails and 1 denotes heads), then we generate an ordered sample of size n with replacement from the population $\{0, 1\}$. If we throw n (distinct) standard dice and record the sequence of scores, then we generate an ordered sample of size n with replacement from the population $\{1, 2, 3, 4, 5, 6\}$.

Suppose that the sampling is without replacement (the most common case). If we record the *ordered* sample $\mathbf{X} = (X_1, X_2, \dots, X_n)$, then the *unordered* sample $\mathbf{W} = \{X_1, X_2, \dots, X_n\}$ is a random variable (that is, a function of \mathbf{X}). On the other hand, if we just record the unordered sample \mathbf{W} in the first place, then we cannot recover the ordered sample. Note also that the number of ordered samples of size n is simply $n!$ times the number of unordered samples of size n . No such simple relationship exists when the sampling is with replacement. This will turn out to be an important point when we study probability models based on random samples, in the next section.

Consider a sample of size $n = 3$ chosen without replacement from the population $\{a, b, c, d, e\}$.

- Give T , the set of unordered samples in list form.
- Give in list form the set of all ordered samples that correspond to the unordered sample $\{b, c, e\}$.
- Note that for every unordered sample, there are 6 ordered samples.
- Give the cardinality of S , the set of ordered samples.

Answer

- $T = \{\{a, b, c\}, \{a, b, d\}, \{a, b, e\}, \{a, c, d\}, \{a, c, e\}, \{a, d, e\}, \{b, c, d\}, \{b, c, e\}, \{b, d, e\}, \{c, d, e\}\}$
- $\{(b, c, e), (b, e, c), (c, b, e), (c, e, b), (e, b, c), (e, c, b)\}$
- 60

Traditionally in probability theory, an *urn* containing *balls* is often used as a metaphor for a finite population.

Suppose that an urn contains 50 (distinct) balls. A sample of 10 balls is selected from the urn. Find the number of samples in each of the following cases:

1. Ordered samples with replacement
2. Ordered samples without replacement
3. Unordered samples without replacement
4. Unordered samples with replacement

Answer

1. 97 656 250 000 000 000
2. 37 276 043 023 296 000
3. 10 272 278 170
4. 62 828 356 305

Suppose again that we have a population D with m (distinct) objects, but suppose now that each object is one of two types—either type 1 or type 0. Such populations are said to be *dichotomous*. Here are some specific examples:

- The population consists of persons, each either *male* or *female*.
- The population consists of voters, each either *democrat* or *republican*.
- The population consists of devices, each either *good* or *defective*.
- The population consists of balls, each either *red* or *green*.

Suppose that the population D has r type 1 objects and hence $m - r$ type 0 objects. Of course, we must have $r \in \{0, 1, \dots, m\}$. Now suppose that we select a sample of size n without replacement from the population. Note that this model has three parameters: the population size m , the number of type 1 objects in the population r , and the sample size n .

Let Y denote the number of type 1 objects in the sample. Then

1. $\#\{Y = k\} = \binom{n}{k} r^{(k)} (m - r)^{(n-k)}$ for each $k \in \{0, 1, \dots, n\}$, if the event is considered as a subset of S , the set of ordered samples.
2. $\#\{Y = k\} = \binom{r}{k} \binom{m-r}{n-k}$ for each $k \in \{0, 1, \dots, n\}$, if the event is considered as a subset of T , the set of unordered samples.
3. The expression in (a) is $n!$ times the expression in (b).

Proof

1. $\binom{n}{k}$ is the number of ways to pick the coordinates (in the ordered sample) where the type 1 objects will go, $r^{(k)}$ is the number of ways to select a permutation of k type 1 objects, and $(m - r)^{(n-k)}$ is the number of ways to select a permutation of $n - k$ type 0 objects. The result follows from the multiplication principle.
2. $\binom{r}{k}$ is the number of ways to select a combination of k type 1 objects and $\binom{m-r}{n-k}$ is the number of ways to select a combination of $n - k$ type 0 objects. The result again follows from the multiplication principle.
3. This result can be shown algebraically, but a combinatorial argument is better. For every combination of size n there are $n!$ permutations of those objects.

A batch of 50 components consists of 40 good components and 10 defective components. A sample of 5 components is selected, without replacement. Let Y denote the number of defectives in the sample.

1. Let S denote the set of ordered samples. Find $\#(S)$.
2. Let T denote the set of unordered samples. Find $\#(T)$.
3. As a subset of T , find $\#\{Y = k\}$ for each $k \in \{0, 1, 2, 3, 4, 5\}$.

Answer

1. 254 251 200
2. 2 118 760
3. $\#\{Y = 0\} = 658 008$ $\#\{Y = 1\} = 913 900$ $\#\{Y = 2\} = 444 600$ $\#\{Y = 3\} = 93 600$ $\#\{Y = 4\} = 8 400$,
 $\#\{Y = 5\} = 252$

Run the simulation of the ball and urn experiment 100 times for the parameter values in the last exercise: $m = 50$, $r = 10$, $n = 5$. Note the values of the random variable Y .

Cards

Recall that a standard *card deck* can be modeled by the Cartesian product set

$$D = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, j, q, k\} \times \{\clubsuit, \diamondsuit, \heartsuit, \spadesuit\} \quad (2.2.8)$$

where the first coordinate encodes the *denomination* or *kind* (ace, 2–10, jack, queen, king) and where the second coordinate encodes the *suit* (clubs, diamonds, hearts, spades). Sometimes we represent a card as a *string* rather than an ordered pair (for example $q\heartsuit$ rather than (q, \heartsuit) for the queen of hearts).

Most card games involve **sampling** without replacement from the deck D , which plays the role of the population. Thus, the basic *card experiment* consists of dealing n cards from a standard deck without replacement; in this special context, the sample of cards is often referred to as a *hand*. Just as in the general sampling model, if we record the *ordered* hand $\mathbf{X} = (X_1, X_2, \dots, X_n)$, then the *unordered* hand $\mathbf{W} = \{X_1, X_2, \dots, X_n\}$ is a random variable (that is, a function of \mathbf{X}). On the other hand, if we just record the unordered hand \mathbf{W} in the first place, then we cannot recover the ordered hand. Finally, recall that $n = 5$ is the *poker experiment* and $n = 13$ is the *bridge experiment*. The game of poker is treated in more detail in the chapter on Games of Chance.

Suppose that a single card is dealt from a standard deck. Let Q denote the event that the card is a queen and H the event that the card is a heart. Give each of the following events in list form:

1. Q
2. H
3. $Q \cup H$
4. $Q \cap H$
5. $Q \setminus H$

Answer

1. $Q = \{q\clubsuit, q\diamondsuit, q\heartsuit, q\spadesuit\}$
2. $H = \{1\heartsuit, 2\heartsuit, \dots, 10\heartsuit, j\heartsuit, q\heartsuit, k\heartsuit\}$
3. $Q \cup H = \{1\heartsuit, 2\heartsuit, \dots, 10\heartsuit, j\heartsuit, q\heartsuit, k\heartsuit, q\clubsuit, q\diamondsuit, q\spadesuit\}$
4. $Q \cap H = \{q\heartsuit\}$
5. $Q \setminus H = \{q\clubsuit, q\diamondsuit, q\spadesuit\}$

In the card experiment, set $n = 1$. Run the experiment 100 times and count the number of times each event in the previous exercise occurs.

Suppose that two cards are dealt from a standard deck and the sequence of cards recorded. Let S denote the set of outcomes, and let Q_i denote the event that the i th card is a queen and H_i the event that the i th card is a heart for $i \in \{1, 2\}$. Find the number of outcomes in each of the following events:

1. S
2. H_1
3. H_2
4. $H_1 \cap H_2$
5. $Q_1 \cap H_1$
6. $Q_1 \cap H_2$
7. $H_1 \cup H_2$

Answer

1. 2652
2. 663
3. 663
4. 156
5. 51

6. 51
7. 1170

Consider the general card experiment in which n cards are dealt from a standard deck, and the ordered hand \mathbf{X} is recorded.

1. Give cardinality of S , the set of values of the ordered hand \mathbf{X} .
2. Give the cardinality of T , the set of values of the unordered hand \mathbf{W} .
3. How many ordered hands correspond to a given unordered hand?
4. Explicitly compute the numbers in (a) and (b) when $n = 5$ (poker).
5. Explicitly compute the numbers in (a) and (b) when $n = 13$ (bridge).

Answer

3. $\#(S) = 52^{(n)}$
4. $\#(T) = \binom{52}{n}$
5. $n!$
6. 311 875 2002 598 960
7. 3 954 242 643 911 239 680 000 501 359 600

Consider the bridge experiment of dealing 13 cards from a deck and recording the unordered hand. In the most common *point counting system*, an ace is worth 4 points, a king 3 points, a queen 2 points, and a jack 1 point. The other cards are worth 0 points. Let S denote the set of outcomes of the experiment and V the point value of the hand.

1. Find the set of possible values of V .
2. Find the cardinality of the event $\{V = 0\}$ as a subset of S .

Answer

1. $\{0, 1, \dots, 37\}$
2. $\#\{V = 0\} = 2\,310\,789\,600$

In the card experiment, set $n = 13$ and run the experiment 100 times. For each run, compute the value of each of the random variable V in the previous exercise.

Consider the poker experiment of dealing 5 cards from a deck. Find the cardinality of each of the events below, as a subset of the set of unordered hands.

1. A : the event that the hand is a *full house* (3 cards of one kind and 2 of another kind).
2. B : the event that the hand has *4 of a kind* (4 cards of one kind and 1 of another kind).
3. C : the event that all cards in the hand are in the same suit (the hand is a *flush* or a *straight flush*).

Answer

1. $\#(A) = 3744$
2. $\#(B) = 624$
3. $\#(C) = 5148$

Run the poker experiment 1000 times. Note the number of times that the events A , B , and C in the previous exercise occurred.

Consider the bridge experiment of dealing 13 cards from a standard deck. Let S denote the set of unordered hands, Y the number of hearts in the hand, and Z the number of queens in the hand.

1. Find the cardinality of the event $\{Y = y\}$ as a subset of S for each $y \in \{0, 1, \dots, 13\}$.
2. Find the cardinality of the event $\{Z = z\}$ as a subset of S for each $z \in \{0, 1, 2, 3, 4\}$.

Answer

1. $\#(Y = y) = \binom{13}{y} \binom{39}{13-y}$ for $y \in \{0, 1, \dots, 13\}$
2. $\#(Z = z) = \binom{4}{z} \binom{48}{4-z}$ for $z \in \{0, 1, 2, 3, 4\}$

Geometric Models

In the experiments that we have considered so far, the sample spaces have all been discrete (so that the set of outcomes is finite or countably infinite). In this subsection, we consider Euclidean sample spaces where the set of outcomes S is *continuous* in a sense that we will make clear later. The experiments we consider are sometimes referred to as *geometric models* because they involve selecting a point *at random* from a Euclidean set.

We first consider *Buffon's coin experiment*, which consists of tossing a coin with radius $r \leq \frac{1}{2}$ randomly on a floor covered with square tiles of side length 1. The coordinates (X, Y) of the center of the coin are recorded relative to axes through the center of the square in which the coin lands. Buffon's experiments are studied in more detail in the chapter on Geometric Models and are named for Comte de Buffon

Figure 2.2.3: Buffon's coin experiment

In Buffon's coin experiment, let S denote the set of outcomes, A the event that the coin does not touch the sides of the square, and let Z denote the distance from the center of the coin to the center of the square.

1. Describe S as a Cartesian product.
2. Describe A as a subset of S .
3. Describe A^c as a subset of S .
4. Express Z as a function on S .
5. Express the event $\{X < Y\}$ as a subset of S .
6. Express the event $\{Z \leq \frac{1}{2}\}$ as a subset of S .

Answer

1. $S = [-\frac{1}{2}, \frac{1}{2}]^2$
2. $A = [r - \frac{1}{2}, \frac{1}{2} - r]^2$
3. $A^c = \{(x, y) \in S : x < r - \frac{1}{2} \text{ or } x > \frac{1}{2} - r \text{ or } y < r - \frac{1}{2} \text{ or } y > \frac{1}{2} - r\}$
4. $Z(x, y) = \sqrt{x^2 + y^2}$ for $(x, y) \in S$
5. $\{X < Y\} = \{(x, y) \in S : x < y\}$
6. $\{Z < \frac{1}{2}\} = \{(x, y) \in S : x^2 + y^2 < \frac{1}{4}\}$

Run Buffon's coin experiment 100 times with $r = 0.2$. For each run, note whether event A occurs and compute the value of random variable Z .

A point (X, Y) is chosen at random in the circular region of radius 1 in \mathbb{R}^2 centered at the origin. Let S denote the set of outcomes. Let A denote the event that the point is in the inscribed square region centered at the origin, with sides parallel to the coordinate axes. Let B denote the event that the point is in the inscribed square with vertices $(\pm 1, 0), (0, \pm 1)$.

1. Describe S mathematically and sketch the set.
2. Describe A mathematically and sketch the set.
3. Describe B mathematically and sketch the set.
4. Sketch $A \cup B$
5. Sketch $A \cap B$
6. Sketch $A \cap B^c$

Answer

1. $S = \{(x, y) : x^2 + y^2 \leq 1\}$

2. $A = \left\{ (x, y) : -\frac{1}{\sqrt{2}} \leq x \leq \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}} \leq y \leq \frac{1}{\sqrt{2}} \right\}$
3. $B = \{(x, y) \in S : -1 \leq |x + y| \leq 1, -1 \leq |y - x| \leq 1\}$

Reliability

In the simple model of *structural reliability*, a system is composed of n components, each of which is either *working* or *failed*. The state of component i is an indicator random variable X_i , where 1 means working and 0 means failure. Thus, $\mathbf{X} = (X_1, X_2, \dots, X_n)$ is a vector of indicator random variables that specifies the states of all of the components, and therefore the set of outcomes of the experiment is $S = \{0, 1\}^n$. The system as a whole is also either working or failed, depending only on the states of the components and how the components are connected together. Thus, the state of the system is also an indicator random variable and is a function of \mathbf{X} . The state of the system (working or failed) as a function of the states of the components is the *structure function*.

A *series system* is working if and only if each component is working. The state of the system is

$$U = X_1 X_2 \cdots X_n = \min \{X_1, X_2, \dots, X_n\} \quad (2.2.9)$$

A *parallel system* is working if and only if at least one component is working. The state of the system is

$$V = 1 - (1 - X_1)(1 - X_2) \cdots (1 - X_n) = \max \{X_1, X_2, \dots, X_n\} \quad (2.2.10)$$

More generally, a k out of n system is working if and only if at least k of the n components are working. Note that a parallel system is a 1 out of n system and a series system is an n out of n system. A k out of $2k$ system is a *majority rules system*.

The state of the k out of n system is $U_{n,k} = \mathbf{1}(\sum_{i=1}^n X_i \geq k)$. The structure function can also be expressed as a polynomial in the variables.

Explicitly give the state of the k out of 3 system, as a polynomial function of the component states (X_1, X_2, X_3) , for each $k \in \{1, 2, 3\}$.

Answer

1. $U_{3,1} = X_1 + X_2 + X_3 - X_1 X_2 - X_1 X_3 - X_2 X_3 + X_1 X_2 X_3$
2. $U_{3,2} = X_1 X_2 + X_1 X_3 + X_2 X_3 - 2 X_1 X_2 X_3$
3. $U_{3,3} = X_1 X_2 X_3$

In some cases, the system can be represented as a *graph* or *network*. The *edges* represent the components and the *vertices* the connections between the components. The system functions if and only if there is a working path between two designated vertices, which we will denote by a and b .

Find the state of the *Wheatstone bridge network* shown below, as a function of the component states. The network is named for Charles Wheatstone.

Answer

Figure 2.2.4: The Wheatstone bridge network

Not every function $u : \{0, 1\}^n \rightarrow \{0, 1\}$ makes sense as a structure function. Explain why the following properties might be desirable:

1. $u(0, 0, \dots, 0) = 0$ and $u(1, 1, \dots, 1) = 1$
2. u is an increasing function, where $\{0, 1\}$ is given the ordinary order and $\{0, 1\}^n$ the corresponding product order.
3. For each $i \in \{1, 2, \dots, n\}$, there exist \mathbf{x} and \mathbf{y} in $\{0, 1\}^n$ all of whose coordinates agree, except $x_i = 0$ and $y_i = 1$, and $u(\mathbf{x}) = 0$ while $u(\mathbf{y}) = 1$.

Answer

1. This means that if all components have failed then the system has failed, and if all components are working then the system is working.
2. This means that if a particular component is changed from failed to working, then the system may also go from failed to working, but not from working to failed. That is, the system can only improve.
3. This means that every component is relevant to the system, that is, there exists a configuration in which changing component i from failed to working changes the system from failed to working.

The model just discussed is a *static model*. We can extend it to a *dynamic model* by assuming that component i is initially working, but has a random *time to failure* T_i , taking values in $[0, \infty)$, for each $i \in \{1, 2, \dots, n\}$. Thus, the basic outcome of the experiment is the random vector of failure times (T_1, T_2, \dots, T_n) , and so the set of outcomes is $[0, \infty)^n$.

Consider the dynamic reliability model for a system with structure function u (valid in the sense of the previous exercise).

1. The state of component i at time $t \geq 0$ is $X_i(t) = \mathbf{1}(T_i > t)$.
2. The state of the system at time t is $X(t) = s[X_1(t), X_2(t), \dots, X_n(t)]$.
3. The time to failure of the system is $T = \min\{t \geq 0 : X(t) = 0\}$.

Suppose that we have two devices and that we record (X, Y) , where X is the failure time of device 1 and Y is the failure time of device 2. Both variables take values in the interval $[0, \infty)$, where the units are in hundreds of hours. Sketch each of the following events:

1. The set of outcomes S
2. $\{X < Y\}$
3. $\{X + Y > 2\}$

Answer

1. $S = [0, \infty)^2$, the first quadrant of the coordinate plane.
2. $\{X < Y\} = \{(x, y) \in S : x < y\}$. This is the region below the diagonal line $x = y$.
3. $\{X + Y > 2\} = \{(x, y) \in S : x + y > 2\}$. This is the region above (or to the right) of the line $x + y = 2$.

Genetics

Please refer to the discussion of genetics in the section on random experiments if you need to review some of the definitions in this section.

Recall first that the *ABO blood type* in humans is determined by three alleles: a , b , and o . Furthermore, o is recessive and a and b are co-dominant.

Suppose that a person is chosen at random and his genotype is recorded. Give each of the following in list form.

1. The set of outcomes S
2. The event that the person is type A
3. The event that the person is type B
4. The event that the person is type AB
5. The event that the person is type O

Answer

1. $S = \{aa, ab, ao, bb, bo, oo\}$
2. $A = \{aa, ao\}$
3. $B = \{bb, bo\}$
4. $AB = \{ab\}$
5. $O = \{oo\}$

Suppose next that pod color in certain type of pea plant is determined by a gene with two alleles: g for green and y for yellow, and that g is dominant.

Suppose that n (distinct) pea plants are collected and the sequence of pod color genotypes is recorded.

1. Give the set of outcomes S in Cartesian product form and find $\#(S)$.
2. Let N denote the number of plants with green pods. Find $\#(N = k)$ (as a subset of S) for each $k \in \{0, 1, \dots, n\}$.

Answer

1. $S = \{gg, gy, yy\}^n$, $\#(S) = 3^n$
2. $\binom{n}{k} 2^k$

Next consider a sex-linked hereditary disorder in humans (such as colorblindness or hemophilia). Let h denote the healthy allele and d the defective allele for the gene linked to the disorder. Recall that d is recessive for women.

Suppose that n women are sampled and the sequence of genotypes is recorded.

1. Give the set of outcomes S in Cartesian product form and find $\#(S)$.
2. Let N denote the number of women who are completely healthy (genotype hh). Find $\#(N = k)$ (as a subset of S) for each $k \in \{0, 1, \dots, n\}$.

Answer

1. $S = \{hh, hd, dd\}^n$, $\#(S) = 3^n$
2. $\binom{n}{k} 2^{n-k}$

Radioactive Emissions

The emission of elementary particles from a sample of radioactive material occurs in a random way. Suppose that the time of emission of the i th particle is a random variable T_i taking values in $(0, \infty)$. If we measure these *arrival times*, then basic outcome vector is (T_1, T_2, \dots) and so the set of outcomes is $S = \{(t_1, t_2, \dots) : 0 < t_1 < t_2 < \dots\}$.

Run the simulation of the gamma experiment in single-step mode for different values of the parameters. Observe the arrival times.

Now let N_t denote the number of emissions in the interval $(0, t]$. Then

1. $N_t = \max \{n \in \mathbb{N}_+ : T_n \leq t\}$.
2. $N_t \geq n$ if and only if $T_n \leq t$.

Run the simulation of the Poisson experiment in single-step mode for different parameter values. Observe the arrivals in the specified time interval.

Statistical Experiments

In the basic cicada experiment, a cicada in the Middle Tennessee area is captured and the following measurements recorded: body weight (in grams), wing length, wing width, and body length (in millimeters), species type, and gender. The cicada data set gives the results of 104 repetitions of this experiment.

1. Define the set of outcomes S for the basic experiment.
2. Let F be the event that a cicada is female. Describe F as a subset of S . Determine whether F occurs for each cicada in the data set.
3. Let V denote the ratio of wing length to wing width. Compute V for each cicada.
4. Give the set of outcomes for the compound experiment that consists of 104 repetitions of the basic experiment.

Answer

For gender, let 0 denote female and 1 male, for species, let 1 denote tredecula, 2 tredecim, and 3 tredecassini.

1. $S = (0, \infty)^4 \times \{0, 1\} \times \{1, 2, 3\}$
2. $F = \{(x_1, x_2, x_3, x_4, y, z) \in S : y = 0\}$
5. S^{104}

In the basic M&M experiment, a bag of M&Ms (of a specified size) is purchased and the following measurements recorded: the number of red, green, blue, yellow, orange, and brown candies, and the net weight (in grams). The M&M data set gives the

results of 30 repetitions of this experiment.

1. Define the set of outcomes S for the basic experiment.
2. Let A be the event that a bag contains at least 57 candies. Describe A as a subset of S .
3. Determine whether A occurs for each bag in the data set.
4. Let N denote the total number of candies. Compute N for each bag in the data set.
5. Give the set of outcomes for the compound experiment that consists of 30 repetitions of the basic experiment.

Answer

1. $S = \mathbb{N}^6 \times (0, \infty)$
2. $A = \{(n_1, n_2, n_3, n_4, n_5, n_6, w) \in S : n_1 + n_2 + \cdots + n_6 > 57\}$
5. S^{30}

2.3: Probability Measures

This section contains the final and most important ingredient in the basic model of a random experiment. If you are a new student of probability, skip the technical details.

Definitions and Interpretations

Suppose that we have a random experiment with sample space (S, \mathcal{S}) , so that S is the set of outcomes of the experiment and \mathcal{S} is the collection of events. When we run the experiment, a given event A either *occurs* or *does not occur*, depending on whether the outcome of the experiment is in A or not. Intuitively, the *probability* of an event is a measure of how likely the event is to occur when we run the experiment. Mathematically, probability is a function on the collection of events that satisfies certain axioms.

Definition

A *probability measure* (or *probability distribution*) \mathbb{P} on the sample space (S, \mathcal{S}) is a real-valued function defined on the collection of events \mathcal{S} that satisfies the following axioms:

1. $\mathbb{P}(A) \geq 0$ for every event A .
2. $\mathbb{P}(S) = 1$.
3. If $\{A_i : i \in I\}$ is a countable, pairwise disjoint collection of events then

$$\mathbb{P}\left(\bigcup_{i \in I} A_i\right) = \sum_{i \in I} \mathbb{P}(A_i) \quad (2.3.1)$$

Details

Recall that the collection of events \mathcal{S} is required to be a σ -algebra, which guarantees that the union of the events in (c) is itself an event. A probability measure is a special case of a positive measure.

Axiom (c) is known as *countable additivity*, and states that the probability of a union of a finite or countably infinite collection of disjoint events is the sum of the corresponding probabilities. The axioms are known as the *Kolmogorov axioms*, in honor of Andrei Kolmogorov who was the first to formalize probability theory in an axiomatic way. More informally, we say that \mathbb{P} is a probability measure (or distribution) on S , the collection of events \mathcal{S} usually being understood.

Axioms (a) and (b) are really just a matter of convention; we choose to measure the probability of an event with a number between 0 and 1 (as opposed, say, to a number between -5 and 7). Axiom (c) however, is fundamental and inescapable. It is required for probability for precisely the same reason that it is required for other measures of the “size” of a set, such as cardinality for finite sets, length for subsets of \mathbb{R} , area for subsets of \mathbb{R}^2 , and volume for subsets of \mathbb{R}^3 . In all these cases, the size of a set that is composed of countably many disjoint pieces is the sum of the sizes of the pieces.

Figure 2.3.1: The union of 4 disjoint events

On the other hand, *uncountable additivity* (the extension of axiom (c) to an uncountable index set I) is unreasonable for probability, just as it is for other measures. For example, an interval of positive length in \mathbb{R} is a union of uncountably many points, each of which has length 0.

We now have defined the three essential ingredients for the model a random experiment:

A *probability space* $(S, \mathcal{S}, \mathbb{P})$ consists of

1. A set of outcomes S
2. A collection of events \mathcal{S}
3. A probability measure \mathbb{P} on the sample space (S, \mathcal{S})

Details

Again, the collection of events \mathcal{S} is a σ -algebra, so that the sample space (S, \mathcal{S}) is a measurable space. The probability space $(S, \mathcal{S}, \mathbb{P})$ is a special case of a positive measure space.

The Law of Large Numbers

Intuitively, the probability of an event is supposed to measure the long-term relative frequency of the event—in fact, this concept was taken as the definition of probability by Richard Von Mises. Here are the relevant definitions:

Suppose that the experiment is repeated indefinitely, and that A is an event. For $n \in \mathbb{N}_+$,

1. Let $N_n(A)$ denote the number of times that A occurred. This is the *frequency* of A in the first n runs.
2. Let $P_n(A) = N_n(A)/n$. This is the *relative frequency* or *empirical probability* of A in the first n runs.

Note that repeating the original experiment indefinitely creates a new, compound experiment, and that $N_n(A)$ and $P_n(A)$ are random variables for the new experiment. In particular, the values of these variables are uncertain until the experiment is run n times. The basic idea is that if we have chosen the correct probability measure for the experiment, then in some sense we expect that the relative frequency of an event should converge to the probability of the event. That is,

$$P_n(A) \rightarrow \mathbb{P}(A) \text{ as } n \rightarrow \infty, \quad A \in \mathcal{S} \quad (2.3.2)$$

regardless of the uncertainty of the relative frequencies on the left. The precise statement of this is the law of large numbers or *law of averages*, one of the fundamental theorems in probability. To emphasize the point, note that in general there will be lots of *possible* probability measures for an experiment, in the sense of the axioms. However, only the probability measure that models the experiment correctly will satisfy the law of large numbers.

Given the data from n runs of the experiment, the empirical probability function P_n is a probability measure on S .

Proof

If we run the experiment n times, we generate n points in S (although of course, some of these points may be the same). The function $A \mapsto N_n(A)$ for $A \subseteq S$ is simply counting measure corresponding to the n points. Clearly $P_n(A) \geq 0$ for an event A and $P_n(S) = n/n = 1$. Countable additivity holds by the addition rule for counting measure.

The Distribution of a Random Variable

Suppose now that X is a random variable for the experiment, taking values in a set T . Recall that mathematically, X is a function from S into T , and $\{X \in B\}$ denotes the event $\{s \in S : X(s) \in B\}$ for $B \subseteq T$. Intuitively, X is a variable of interest for the experiment, and every meaningful statement about X defines an event.

The function $B \mapsto \mathbb{P}(X \in B)$ for $B \subseteq T$ defines a probability measure on T .

Proof

Figure 2.3.2: A set $B \in \mathcal{T}$ corresponds to the event $\{X \in B\} \in \mathcal{S}$

The probability measure in (5) is called the *probability distribution* of X , so we have all of the ingredients for a new probability space.

A random variable X with values in T defines a new probability space:

1. T is the set of outcomes.
2. Subsets of T are the events.
3. The probability distribution of X is the probability measure on T .

This probability space corresponds to the new random experiment in which the outcome is X . Moreover, recall that the outcome of the experiment itself can be thought of as a random variable. Specifically, if we let $T = S$ we let X be the identity function on S , so that $X(s) = s$ for $s \in S$. Then X is a random variable with values in S and $\mathbb{P}(X \in A) = \mathbb{P}(A)$ for each event A . Thus, every probability measure can be thought of as the distribution of a random variable.

Constructions

Measures

How can we construct probability measures? As noted briefly above, there are other measures of the “size” of sets; in many cases, these can be converted into probability measures. First, a positive measure μ on the sample space (S, \mathcal{S}) is a real-valued function defined on \mathcal{S} that satisfies axioms (a) and (c) in (1), and then (S, \mathcal{S}, μ) is a *measure space*. In general, $\mu(A)$ is allowed to be infinite. However, if $\mu(S)$ is positive and finite (so that μ is a *finite positive measure*), then μ can easily be re-scaled into a probability measure.

If μ is a positive measure on S with $0 < \mu(S) < \infty$ then \mathbb{P} defined below is a probability measure.

$$\mathbb{P}(A) = \frac{\mu(A)}{\mu(S)}, \quad A \in \mathcal{S} \quad (2.3.3)$$

Proof

1. $\mathbb{P}(A) \geq 0$ since $\mu(A) \geq 0$ and $0 < \mu(S) < \infty$.
2. $\mathbb{P}(S) = \mu(S)/\mu(S) = 1$
3. If $\{A_i : i \in I\}$ is a countable collection of disjoint events then

$$\mathbb{P}\left(\bigcup_{i \in I} A_i\right) = \frac{1}{\mu(S)} \mu\left(\bigcup_{i \in I} A_i\right) = \frac{1}{\mu(S)} \sum_{i \in I} \mu(A_i) = \sum_{i \in I} \frac{\mu(A_i)}{\mu(S)} = \sum_{i \in I} \mathbb{P}(A_i) \quad (2.3.4)$$

In this context, $\mu(S)$ is called the *normalizing constant*. In the next two subsections, we consider some very important special cases.

Discrete Distributions

In this discussion, we assume that the sample space (S, \mathcal{S}) is *discrete*. Recall that this means that the set of outcomes S is countable and that $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S , so that every subset is an event. The standard measure on a discrete space is counting measure $\#$, so that $\#(A)$ is the number of elements in A for $A \subseteq S$. When S is finite, the probability measure corresponding to counting measure as constructed in above is particularly important in combinatorial and sampling experiments.

Suppose that S is a finite, nonempty set. The *discrete uniform distribution* on S is given by

$$\mathbb{P}(A) = \frac{\#(A)}{\#(S)}, \quad A \subseteq S \quad (2.3.5)$$

The underlying model is referred to as the *classical probability model*, because historically the very first problems in probability (involving coins and dice) fit this model.

In the general discrete case, if \mathbb{P} is a probability measure on S , then since S is countable, it follows from countable additivity that \mathbb{P} is completely determined by its values on the singleton events. Specifically, if we define $f(x) = \mathbb{P}(\{x\})$ for $x \in S$, then $\mathbb{P}(A) = \sum_{x \in A} f(x)$ for every $A \subseteq S$. By axiom (a), $f(x) \geq 0$ for $x \in S$ and by axiom (b), $\sum_{x \in S} f(x) = 1$. Conversely, we can give a general construction for defining a probability measure on a discrete space.

Suppose that $g: S \rightarrow [0, \infty)$. Then μ defined by $\mu(A) = \sum_{x \in A} g(x)$ for $A \subseteq S$ is a positive measure on S . If $0 < \mu(S) < \infty$ then \mathbb{P} defined as follows is a probability measure on S .

$$\mathbb{P}(A) = \frac{\mu(A)}{\mu(S)} = \frac{\sum_{x \in A} g(x)}{\sum_{x \in S} g(x)}, \quad A \subseteq S \quad (2.3.6)$$

Proof

Trivially $\mu(A) \geq 0$ for $A \subseteq S$ since g is nonnegative. The countable additivity property holds since the terms in a sum of nonnegative numbers can be rearranged in any way without altering the sum. Thus let $\{A_i : i \in I\}$ be a countable collection of disjoint subsets of S , and let $A = \bigcup_{i \in I} A_i$ then

$$\mu(A) = \sum_{x \in A} g(x) = \sum_{i \in I} \sum_{x \in A_i} g(x) = \sum_{i \in I} \mu(A_i) \quad (2.3.7)$$

If $0 < \mu(S) < \infty$ then \mathbb{P} is a probability measure by [scaling result](#) above.

In the context of our previous remarks, $f(x) = g(x)/\mu(S) = g(x)/\sum_{y \in S} g(y)$ for $x \in S$. Distributions of this type are said to be *discrete*. Discrete distributions are studied in detail in the chapter on Distributions.

If S is finite and g is a constant function, then the probability measure \mathbb{P} associated with g is the discrete uniform distribution on S .

Proof

Suppose that $g(x) = c$ for $x \in S$ where $c > 0$. Then $\mu(A) = c\#(A)$ and hence $\mathbb{P}(A) = \mu(A)/\mu(S) = \#(A)/\#(S)$ for $A \subseteq S$.

Continuous Distributions

The probability distributions that we will construct next are *continuous distributions* on \mathbb{R}^n for $n \in \mathbb{N}_+$ and require some calculus.

For $n \in \mathbb{N}_+$, the standard measure λ_n on \mathbb{R}^n is given by

$$\lambda_n(A) = \int_A 1 \, dx, \quad A \subseteq \mathbb{R}^n \quad (2.3.8)$$

In particular, $\lambda_1(A)$ is the length of $A \subseteq \mathbb{R}$, $\lambda_2(A)$ is the area of $A \subseteq \mathbb{R}^2$, and $\lambda_3(A)$ is the volume of $A \subseteq \mathbb{R}^3$.

Details

Technically, λ_n is Lebesgue measure on the measurable subsets of \mathbb{R}^n , named for Henri Lebesgue. The representation above in terms of the ordinary Riemann integral of calculus is valid for the subsets that typically occur in applications. As usual, all subsets of \mathbb{R}^n in the discussion below are assumed to be measurable.

When $n > 3$, $\lambda_n(A)$ is sometimes called the *n-dimensional volume* of $A \subseteq \mathbb{R}^n$. The probability measure associated with λ_n on a set with positive, finite *n-dimensional volume* is particularly important.

Suppose that $S \subseteq \mathbb{R}^n$ with $0 < \lambda_n(S) < \infty$. The *continuous uniform distribution* on S is defined by

$$\mathbb{P}(A) = \frac{\lambda_n(A)}{\lambda_n(S)}, \quad A \subseteq S \quad (2.3.9)$$

Note that the continuous uniform distribution is analogous to the discrete uniform distribution defined in (8), but with Lebesgue measure λ_n replacing counting measure $\#$. We can generalize this construction to produce many other distributions.

Suppose again that $S \subseteq \mathbb{R}^n$ and that $g : S \rightarrow [0, \infty)$. Then μ defined by $\mu(A) = \int_A g(x) \, dx$ for $A \subseteq S$ is a positive measure on S . If $0 < \mu(S) < \infty$, then \mathbb{P} defined as follows is a probability measure on S .

$$\mathbb{P}(A) = \frac{\mu(A)}{\mu(S)} = \frac{\int_A g(x) \, dx}{\int_S g(x) \, dx}, \quad A \in \mathcal{S} \quad (2.3.10)$$

Proof

Technically, the integral in the definition of $\mu(A)$ is the Lebesgue integral, but this integral agrees with the ordinary Riemann integral of calculus when g and A are sufficiently nice. The function g is assumed to be measurable and is the density function of μ with respect to λ_n . Technicalities aside, the proof is straightforward:

1. $\mu(A) \geq 0$ for $A \subseteq S$ since g is nonnegative.
2. If $\{A_i : i \in I\}$ is a countable disjoint collection of subsets of S and $A = \bigcup_{i \in I} A_i$, then by a basic property of the integral,

$$\mu(A) = \int_A g(x) dx = \sum_{i \in I} \int_{A_i} g(x) dx = \sum_{i \in I} \mu(A_i) \quad (2.3.11)$$

If $0 < \mu(S) < \infty$ then \mathbb{P} is a probability measure on S by the [scaling result](#) above.

Distributions of this type are said to be *continuous*. Continuous distributions are studied in detail in the chapter on Distributions. Note that the continuous distribution above is analogous to the discrete distribution in (9), but with integrals replacing sums. The general theory of integration allows us to unify these two special cases, and many others besides.

Rules of Probability

Basic Rules

Suppose again that we have a random experiment modeled by a probability space $(S, \mathcal{S}, \mathbb{P})$, so that S is the set of outcomes, \mathcal{S} the collection of events, and \mathbb{P} the probability measure. In the following theorems, A and B are events. The results follow easily from the axioms of probability in (1), so be sure to try the proofs yourself before reading the ones in the text.

$\mathbb{P}(A^c) = 1 - \mathbb{P}(A)$. This is known as the *complement rule*.

Proof

Figure 2.3.3: The complement rule

$\mathbb{P}(\emptyset) = 0$.

Proof

This follows from the the complement rule applied to $A = S$.

$\mathbb{P}(B \setminus A) = \mathbb{P}(B) - \mathbb{P}(A \cap B)$. This is known as the *difference rule*.

Proof

Figure 2.3.4: The difference rule

If $A \subseteq B$ then $\mathbb{P}(B \setminus A) = \mathbb{P}(B) - \mathbb{P}(A)$.

Proof

This result is a corollary of the difference rule. Note that $A \cap B = A$.

Recall that if $A \subseteq B$ we sometimes write $B - A$ for the set difference, rather than $B \setminus A$. With this notation, the difference rule has the nice form $\mathbb{P}(B - A) = \mathbb{P}(B) - \mathbb{P}(A)$.

If $A \subseteq B$ then $\mathbb{P}(A) \leq \mathbb{P}(B)$.

Proof

This result is a corollary of the previous result. Note that $\mathbb{P}(B \setminus A) \geq 0$ and hence $\mathbb{P}(B) - \mathbb{P}(A) \geq 0$.

Thus, \mathbb{P} is an increasing function, relative to the subset partial order on the collection of events \mathcal{S} , and the ordinary order on \mathbb{R} . In particular, it follows that $\mathbb{P}(A) \leq 1$ for any event A .

Figure 2.3.5: The increasing property

Suppose that $A \subseteq B$.

1. If $\mathbb{P}(B) = 0$ then $\mathbb{P}(A) = 0$.
2. If $\mathbb{P}(A) = 1$ then $\mathbb{P}(B) = 1$.

Proof

This follows immediately from the increasing property in the last theorem.

The Boole and Bonferroni Inequalities

The next result is known as *Boole's inequality*, named after George Boole. The inequality gives a simple upper bound on the probability of a union.

If $\{A_i : i \in I\}$ is a countable collection of events then

$$\mathbb{P}\left(\bigcup_{i \in I} A_i\right) \leq \sum_{i \in I} \mathbb{P}(A_i) \quad (2.3.12)$$

Proof

Figure 2.3.6: Boole's inequality

Intuitively, Boole's inequality holds because parts of the union have been measured more than once in the sum of the probabilities on the right. Of course, the sum of the probabilities may be greater than 1, in which case Boole's inequality is not helpful. The following result is a simple consequence of *Boole's inequality*.

If $\{A_i : i \in I\}$ is a countable collection of events with $\mathbb{P}(A_i) = 0$ for each $i \in I$, then

$$\mathbb{P}\left(\bigcup_{i \in I} A_i\right) = 0 \quad (2.3.13)$$

An event A with $\mathbb{P}(A) = 0$ is said to be *null*. Thus, a countable union of null events is still a null event.

The next result is known as *Bonferroni's inequality*, named after Carlo Bonferroni. The inequality gives a simple lower bound for the probability of an intersection.

If $\{A_i : i \in I\}$ is a countable collection of events then

$$\mathbb{P}\left(\bigcap_{i \in I} A_i\right) \geq 1 - \sum_{i \in I} [1 - \mathbb{P}(A_i)] \quad (2.3.14)$$

Proof

By De Morgan's law, $(\bigcap_{i \in I} A_i)^c = \bigcup_{i \in I} A_i^c$. Hence by *Boole's inequality*,

$$\mathbb{P} \left[\left(\bigcap_{i \in I} A_i \right)^c \right] \leq \sum_{i \in I} \mathbb{P}(A_i^c) = \sum_{i \in I} [1 - \mathbb{P}(A_i)] \quad (2.3.15)$$

Using the complement rule again gives Bonferroni's inequality.

Of course, the lower bound in Bonferroni's inequality may be less than or equal to 0, in which case it's not helpful. The following result is a simple consequence of Bonferroni's inequality.

If $\{A_i : i \in I\}$ is a countable collection of events with $\mathbb{P}(A_i) = 1$ for each $i \in I$, then

$$\mathbb{P} \left(\bigcap_{i \in I} A_i \right) = 1 \quad (2.3.16)$$

An event A with $\mathbb{P}(A) = 1$ is sometimes called *almost sure* or *almost certain*. Thus, a countable intersection of almost sure events is still almost sure.

Suppose that A and B are events in an experiment.

1. If $\mathbb{P}(A) = 0$, then $\mathbb{P}(A \cup B) = \mathbb{P}(B)$.
2. If $\mathbb{P}(A) = 1$, then $\mathbb{P}(A \cap B) = \mathbb{P}(B)$.

Proof

1. Using the [increasing property](#) and [Boole's inequality](#) we have $\mathbb{P}(B) \leq \mathbb{P}(A \cup B) \leq \mathbb{P}(A) + \mathbb{P}(B) = \mathbb{P}(B)$
2. Using the [increasing property](#) and [Bonferroni's inequality](#) we have $\mathbb{P}(B) = \mathbb{P}(A) + \mathbb{P}(B) - 1 \leq \mathbb{P}(A \cap B) \leq \mathbb{P}(B)$

The Partition Rule

Suppose that $\{A_i : i \in I\}$ is a countable collection of events that partition S . Recall that this means that the events are disjoint and their union is S . For any event B ,

$$\mathbb{P}(B) = \sum_{i \in I} \mathbb{P}(A_i \cap B) \quad (2.3.17)$$

Proof

Figure 2.3.7: The partition rule

Naturally, this result is useful when the probabilities of the intersections are known. Partitions usually arise in connection with a random variable. Suppose that X is a random variable taking values in a countable set T , and that B is an event. Then

$$\mathbb{P}(B) = \sum_{x \in T} \mathbb{P}(X = x, B) \quad (2.3.18)$$

In this formula, note that the comma acts like the intersection symbol in the previous formula.

The Inclusion-Exclusion Rule

The inclusion-exclusion formulas provide a method for computing the probability of a union of events in terms of the probabilities of the various intersections of the events. The formula is useful because often the probabilities of the intersections are easier to compute. Interestingly, however, the same formula works for computing the probability of an intersection of events in terms of the probabilities of the various unions of the events. This version is rarely stated, because it's simply not that useful. We start with two events.

If A, B are events then $\mathbb{P}(A \cup B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B)$.

Figure 2.3.8: The probability of the union of two events

Here is the complementary result for the intersection in terms of unions:

If A, B are events then $\mathbb{P}(A \cap B) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cup B)$.

Proof

This follows immediately from the previous formula by rearranging the terms

Next we consider three events.

If A, B, C are events then $\mathbb{P}(A \cup B \cup C) = \mathbb{P}(A) + \mathbb{P}(B) + \mathbb{P}(C) - \mathbb{P}(A \cap B) - \mathbb{P}(A \cap C) - \mathbb{P}(B \cap C) + \mathbb{P}(A \cap B \cap C)$.

Analytic Proof

First note that $A \cup B \cup C = (A \cup B) \cup [C \setminus (A \cup B)]$. The event in parentheses and the event in square brackets are disjoint. Thus, using the additivity axiom and the difference rule,

$$\mathbb{P}(A \cup B \cup C) = \mathbb{P}(A \cup B) + \mathbb{P}(C) - \mathbb{P}[C \cap (A \cup B)] = \mathbb{P}(A \cup B) + \mathbb{P}(C) - \mathbb{P}[(C \cap A) \cup (C \cap B)] \quad (2.3.19)$$

Using the [inclusion-exclusion rule for two events](#) (twice) we have

$$\mathbb{P}(A \cup B \cup C) = \mathbb{P}(A) + \mathbb{P}(B) - \mathbb{P}(A \cap B) + \mathbb{P}(C) - [\mathbb{P}(C \cap A) + \mathbb{P}(C \cap B) - \mathbb{P}(A \cap B \cap C)] \quad (2.3.20)$$

Proof by accounting

Figure 2.3.8: The probability of the union of three events

Here is the complementary result for the probability of an intersection in terms of the probabilities of the unions:

If A, B, C are events then $\mathbb{P}(A \cap B \cap C) = \mathbb{P}(A) + \mathbb{P}(B) + \mathbb{P}(C) - \mathbb{P}(A \cup B) - \mathbb{P}(A \cup C) - \mathbb{P}(B \cup C) + \mathbb{P}(A \cup B \cup C)$.

Proof

This follows from solving for $\mathbb{P}(A \cap B \cap C)$ in the previous result, and then using the [result for two events](#) on $\mathbb{P}(A \cap B)$, $\mathbb{P}(B \cap C)$, and $\mathbb{P}(A \cap C)$.

The inclusion-exclusion formulas for two and three events can be generalized to n events. For the remainder of this discussion, suppose that $\{A_i : i \in I\}$ is a collection of events where I is an index set with $\#(I) = n$.

The general *inclusion-exclusion formula* for the probability of a union.

$$\mathbb{P}\left(\bigcup_{i \in I} A_i\right) = \sum_{k=1}^n (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mathbb{P}\left(\bigcap_{j \in J} A_j\right) \quad (2.3.21)$$

Proof by induction

The proof is by induction on n . We have already established the formula for $n = 2$ and $n = 3$. Thus, suppose that the inclusion-exclusion formula holds for a given n , and suppose that $(A_1, A_2, \dots, A_{n+1})$ is a sequence of $n + 1$ events. Then

$$\bigcup_{i=1}^{n+1} A_i = \left(\bigcup_{i=1}^n A_i \right) \cup \left[A_{n+1} \setminus \left(\bigcup_{i=1}^n A_i \right) \right] \quad (2.3.22)$$

As before, the event in parentheses and the event in square brackets are disjoint. Thus using the additivity axiom, the difference rule, and the distributive rule we have

$$\mathbb{P} \left(\bigcup_{i=1}^{n+1} A_i \right) = \mathbb{P} \left(\bigcup_{i=1}^n A_i \right) + \mathbb{P}(A_{n+1}) - \mathbb{P} \left(\bigcup_{i=1}^n (A_{n+1} \cap A_i) \right) \quad (2.3.23)$$

By the induction hypothesis, the inclusion-exclusion formula holds for each union of n events on the right. Applying the formula and simplifying gives the inclusion-exclusion formula for $n + 1$ events.

Proof by accounting

This is the general version of the same argument we used [above](#) for 3 events. $\bigcup_{i \in I} A_i$ is the union of the disjoint events of the form $(\bigcap_{i \in K} A_i) \cap (\bigcap_{i \in K^c} A_i)$ where K is a nonempty subset of the index set I . In the inclusion-exclusion formula, the event corresponding to a given K is measured in $\mathbb{P}(\bigcap_{j \in J} A_j)$ for every nonempty $J \subseteq K$. Suppose that $\#(K) = k$. Accounting for the positive and negative signs, the net measurement is $\sum_{j=1}^k (-1)^{j-1} \binom{k}{j} = 1$.

Here is the complementary result for the probability of an intersection in terms of the probabilities of the various unions:

The general *inclusion-exclusion formula* for the probability of an intersection.

$$\mathbb{P} \left(\bigcap_{i \in I} A_i \right) = \sum_{k=1}^n (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mathbb{P} \left(\bigcup_{j \in J} A_j \right) \quad (2.3.24)$$

The general inclusion-exclusion formulas are not worth remembering *in detail*, but only *in pattern*. For the probability of a union, we start with the sum of the probabilities of the events, then subtract the probabilities of all of the paired intersections, then add the probabilities of the third-order intersections, and so forth, alternating signs, until we get to the probability of the intersection of all of the events.

The *general Bonferroni inequalities* (for a union) state that if sum on the right in the general inclusion-exclusion formula is truncated, then the truncated sum is an *upper bound* or a *lower bound* for the probability on the left, depending on whether the last term has a positive or negative sign. Here is the result stated explicitly:

Suppose that $m \in \{1, 2, \dots, n-1\}$. Then

1. $\mathbb{P} \left(\bigcup_{i \in I} A_i \right) \leq \sum_{k=1}^m (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mathbb{P} \left(\bigcap_{j \in J} A_j \right)$ if m is odd.
2. $\mathbb{P} \left(\bigcup_{i \in I} A_i \right) \geq \sum_{k=1}^m (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mathbb{P} \left(\bigcap_{j \in J} A_j \right)$ if m is even.

Proof

Let $P_k = \sum_{J \subseteq I, \#(J)=k} \mathbb{P} \left(\bigcap_{j \in J} A_j \right)$, the absolute value of the k th term in the inclusion-exclusion formula. The result follows since the inclusion-exclusion formula is an alternating series, and P_k is decreasing in k .

More elegant proofs of the inclusion-exclusion formula and the Bonferroni inequalities can be constructed using expected value.

Note that there is a probability term in the inclusion-exclusion formulas for every nonempty subset J of the index set I , with either a positive or negative sign, and hence there are $2^n - 1$ such terms. These probabilities suffice to compute the probability of *any* event that can be constructed from the given events, not just the union or the intersection.

The probability of any event that can be constructed from $\{A_i : i \in I\}$ can be computed from either of the following collections of $2^n - 1$ probabilities:

1. $\mathbb{P} \left(\bigcap_{j \in J} A_j \right)$ where J is a nonempty subset of I .
2. $\mathbb{P} \left(\bigcup_{j \in J} A_j \right)$ where J is a nonempty subset of I .

Remark

If you go back and look at your proofs of the [rules of probability](#) above, you will see that they hold for any finite measure μ , not just probability. The only change is that the number 1 is replaced by $\mu(S)$. In particular, the inclusion-exclusion rule is as important in combinatorics (the study of counting measure) as it is in probability.

Examples and Applications

Probability Rules

Suppose that A and B are events in an experiment with $\mathbb{P}(A) = \frac{1}{3}$, $\mathbb{P}(B) = \frac{1}{4}$, $\mathbb{P}(A \cap B) = \frac{1}{10}$. Express each of the following events in the language of the experiment and find its probability:

1. $A \setminus B$
2. $A \cup B$
3. $A^c \cup B^c$
4. $A^c \cap B^c$
5. $A \cup B^c$

Answer

1. A occurs but not B . $\frac{7}{30}$
2. A or B occurs. $\frac{29}{60}$
3. One of the events does not occur. $\frac{9}{10}$
4. Neither event occurs. $\frac{31}{60}$
5. Either A occurs or B does not occur. $\frac{17}{20}$

Suppose that A , B , and C are events in an experiment with $\mathbb{P}(A) = 0.3$, $\mathbb{P}(B) = 0.2$, $\mathbb{P}(C) = 0.4$, $\mathbb{P}(A \cap B) = 0.04$, $\mathbb{P}(A \cap C) = 0.1$, $\mathbb{P}(B \cap C) = 0.1$, $\mathbb{P}(A \cap B \cap C) = 0.01$. Express each of the following events in set notation and find its probability:

1. At least one of the three events occurs.
2. None of the three events occurs.
3. Exactly one of the three events occurs.
4. Exactly two of the three events occur.

Answer

1. $\mathbb{P}(A \cup B \cup C) = 0.67$
2. $\mathbb{P}[(A \cup B \cup C)^c] = 0.37$
3. $\mathbb{P}[(A \cap B^c \cap C^c) \cup (A^c \cap B \cap C^c) \cup (A^c \cap B^c \cap C)] = 0.45$
4. $\mathbb{P}[(A \cap B \cap C^c) \cup (A \cap B^c \cap C) \cup (A^c \cap B \cap C)] = 0.21$

Suppose that A and B are events in an experiment with $\mathbb{P}(A \setminus B) = \frac{1}{6}$, $\mathbb{P}(B \setminus A) = \frac{1}{4}$, and $\mathbb{P}(A \cap B) = \frac{1}{12}$. Find the probability of each of the following events:

1. A
2. B
3. $A \cup B$
4. $A^c \cup B^c$
5. $A^c \cap B^c$

Answer

1. $\frac{1}{4}$
2. $\frac{1}{3}$
3. $\frac{1}{2}$
4. $\frac{11}{12}$

5. $\frac{1}{2}$

Suppose that A and B are events in an experiment with $\mathbb{P}(A) = \frac{2}{5}$, $\mathbb{P}(A \cup B) = \frac{7}{10}$, and $\mathbb{P}(A \cap B) = \frac{1}{6}$. Find the probability of each of the following events:

1. B
2. $A \setminus B$
3. $B \setminus A$
4. $A^c \cup B^c$
5. $A^c \cap B^c$

Answer

1. $\frac{7}{15}$
2. $\frac{7}{30}$
3. $\frac{3}{10}$
4. $\frac{5}{6}$
5. $\frac{3}{10}$

Suppose that A , B , and C are events in an experiment with $\mathbb{P}(A) = \frac{1}{3}$, $\mathbb{P}(B) = \frac{1}{4}$, $\mathbb{P}(C) = \frac{1}{5}$.

1. Use [Boole's inequality](#) to find an upper bound for $\mathbb{P}(A \cup B \cup C)$.
2. Use [Bonferroni's inequality](#) to find a lower bound for $\mathbb{P}(A \cap B \cap C)$.

Answer

1. $\frac{47}{60}$
2. $-\frac{83}{60}$, not helpful.

Open the simple probability experiment.

1. Note the 16 events that can be constructed from A and B using the set operations of union, intersection, and complement.
2. Given $\mathbb{P}(A)$, $\mathbb{P}(B)$, and $\mathbb{P}(A \cap B)$ in the table, use the rules of probability to verify the probabilities of the other events.
3. Run the experiment 1000 times and compare the relative frequencies of the events with the probabilities of the events.

Suppose that A , B , and C are events in a random experiment with $\mathbb{P}(A) = 1/4$, $\mathbb{P}(B) = 1/3$, $\mathbb{P}(C) = 1/6$, $\mathbb{P}(A \cap B) = 1/18$, $\mathbb{P}(A \cap C) = 1/16$, $\mathbb{P}(B \cap C) = 1/12$, and $\mathbb{P}(A \cap B \cap C) = 1/24$. Find the probabilities of the various unions:

1. $A \cup B$
2. $A \cup C$
3. $B \cup C$
4. $A \cup B \cup C$

Answer

1. $19/36$
2. $17/48$
3. $5/12$
4. $85/144$

Suppose that A , B , and C are events in a random experiment with $\mathbb{P}(A) = 1/4$, $\mathbb{P}(B) = 1/4$, $\mathbb{P}(C) = 5/16$, $\mathbb{P}(A \cup B) = 7/16$, $\mathbb{P}(A \cup C) = 23/48$, $\mathbb{P}(B \cup C) = 11/24$, and $\mathbb{P}(A \cup B \cup C) = 7/12$. Find the probabilities of the various intersections:

1. $A \cap B$
2. $A \cap C$
3. $B \cap C$

4. $A \cap B \cap C$

Answer

1. $1/16$
2. $1/12$
3. $5/48$
4. $1/48$

Suppose that A , B , and C are events in a random experiment. Explicitly give all of the Bonferroni inequalities for $\mathbb{P}(A \cup B \cup C)$

Proof

1. $\mathbb{P}(A \cup B \cup C) \leq \mathbb{P}(A) + \mathbb{P}(B) + \mathbb{P}(C)$
2. $\mathbb{P}(A \cup B \cup C) \geq \mathbb{P}(A) + \mathbb{P}(B) + \mathbb{P}(C) - \mathbb{P}(A \cap B) - \mathbb{P}(A \cap C) - \mathbb{P}(B \cap C)$
3. $\mathbb{P}(A \cup B \cup C) = \mathbb{P}(A) + \mathbb{P}(B) + \mathbb{P}(C) - \mathbb{P}(A \cap B) - \mathbb{P}(A \cap C) - \mathbb{P}(B \cap C) + \mathbb{P}(A \cap B \cap C)$

Coins

Consider the random experiment of tossing a coin n times and recording the sequence of scores $\mathbf{X} = (X_1, X_2, \dots, X_n)$ (where 1 denotes heads and 0 denotes tails). This experiment is a generic example of n Bernoulli trials, named for Jacob Bernoulli. Note that the set of outcomes is $S = \{0, 1\}^n$, the set of *bit strings* of length n . If the coin is *fair*, then presumably, by the very meaning of the word, we have no reason to prefer one point in S over another. Thus, as a modeling assumption, it seems reasonable to give S the [uniform probability distribution](#) in which all outcomes are equally likely.

Suppose that a fair coin is tossed 3 times and the sequence of coin scores is recorded. Let A be the event that the first coin is heads and B the event that there are exactly 2 heads. Give each of the following events in list form, and then compute the probability of the event:

1. A
2. B
3. $A \cap B$
4. $A \cup B$
5. $A^c \cup B^c$
6. $A^c \cap B^c$
7. $A \cup B^c$

Answer

1. $\{100, 101, 110, 111\} \frac{1}{2}$
2. $\{110, 101, 011\} \frac{3}{8}$
3. $\{110, 101\} \frac{1}{4}$
4. $\{100, 101, 110, 111, 011\} \frac{5}{8}$
5. $\{000, 001, 010, 100, 011, 111\} \frac{3}{4}$
6. $\{000, 001, 010\} \frac{3}{8}$
7. $\{100, 101, 110, 111, 000, 010, 001\} \frac{7}{8}$

In the Coin experiment, select 3 coins. Run the experiment 1000 times, updating after every run, and compute the empirical probability of each event in the previous exercise.

Suppose that a fair coin is tossed 4 times and the sequence of scores is recorded. Let Y denote the number of heads. Give the event $\{Y = k\}$ (as a subset of the sample space) in list form, for each $k \in \{0, 1, 2, 3, 4\}$, and then give the probability of the event.

Answer

1. $\{Y = 0\} = \{0000\}, \mathbb{P}(Y = 0) = \frac{1}{16}$
2. $\{Y = 1\} = \{1000, 0100, 0010, 0001\}, \mathbb{P}(Y = 1) = \frac{4}{16}$

3. $\{Y = 2\} = \{1100, 1010, 1001, 0110, 0101, 0011\}$, $\mathbb{P}(Y = 2) = \frac{6}{16}$
4. $\{Y = 3\} = \{1110, 1101, 1011, 0111\}$, $\mathbb{P}(Y = 3) = \frac{4}{16}$
5. $\{Y = 4\} = \{1111\}$, $\mathbb{P}(Y = 4) = \frac{1}{16}$

Suppose that a fair coin is tossed n times and the sequence of scores is recorded. Let Y denote the number of heads.

$$\mathbb{P}(Y = k) = \binom{n}{k} \left(\frac{1}{2}\right)^n, \quad k \in \{0, 1, \dots, n\} \quad (2.3.25)$$

Proof

The number of bit strings of length n is 2^n , and since the coin is fair, these are equally likely. The number of bit strings of length n with exactly k 1's is $\binom{n}{k}$. Hence the probability of 1 occurring exactly k times is $\binom{n}{k}/2^n$.

The distribution of Y in the last exercise is a special case of the *binomial distribution*. The binomial distribution is studied in more detail in the chapter on Bernoulli Trials.

Dice

Consider the experiment of throwing n distinct, k -sided dice (with faces numbered from 1 to k) and recording the sequence of scores $\mathbf{X} = (X_1, X_2, \dots, X_n)$. We can record the outcome as a *sequence* because of the assumption that the dice are distinct; you can think of the dice as somehow labeled from 1 to n , or perhaps with different colors. The special case $k = 6$ corresponds to *standard dice*. In general, note that the set of outcomes is $S = \{1, 2, \dots, k\}^n$. If the dice are *fair*, then again, by the very meaning of the word, we have no reason to prefer one point in S over another, so as a modeling assumption it seems reasonable to give S the *uniform probability distribution*.

Suppose that two fair, standard dice are thrown and the sequence of scores recorded. Let A denote the event that the first die score is less than 3 and B the event that the sum of the dice scores is 6. Give each of the following events in list form and then find the probability of the event.

1. A
2. B
3. $A \cap B$
4. $A \cup B$
5. $B \setminus A$

Answer

1. $\{(1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (1, 6), (2, 1), (2, 2), (2, 3), (2, 4), (2, 5), (2, 6)\}$, $\frac{12}{36}$
2. $\{(1, 5), (5, 1), (2, 4), (4, 2), (3, 3)\}$, $\frac{5}{36}$
3. $\{(1, 5), (2, 4)\}$, $\frac{2}{36}$
4. $\{(1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (1, 6), (2, 1), (2, 2), (2, 3), (2, 4), (2, 5), (2, 6), (5, 1), (4, 2), (3, 3)\}$, $\frac{15}{36}$
5. $\{(5, 1), (4, 2), (3, 3)\}$, $\frac{3}{36}$

In the dice experiment, set $n = 2$. Run the experiment 100 times and compute the empirical probability of each event in the previous exercise.

Consider again the dice experiment with $n = 2$ fair dice. Let S denote the set of outcomes, Y the sum of the scores, U the minimum score, and V the maximum score.

1. Express Y as a function on S and give the set of values.
2. Find $\mathbb{P}(Y = y)$ for each y in the set in part (a).
3. Express U as a function on S and give the set of values.
4. Find $\mathbb{P}(U = u)$ for each u in the set in part (c).
5. Express V as a function on S and give the set of values.
6. Find $\mathbb{P}(V = v)$ for each v in the set in part (e).
7. Find the set of values of (U, V) .

8. Find $\mathbb{P}(U = u, V = v)$ for each (u, v) in the set in part (g).

Answer

Note that $S = \{1, 2, 3, 4, 5, 6\}^2$

1. $Y(x_1, x_2) = x_1 + x_2$ for $(x_1, x_2) \in S$. The set of values is $\{2, 3, \dots, 12\}$

2.	y	2	3	4	5	6	7	8	9	10	11	12
	$\mathbb{P}(Y = y)$	$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$

3. $U(x_1, x_2) = \min\{x_1, x_2\}$ for $(x_1, x_2) \in S$. The set of values is $\{1, 2, 3, 4, 5, 6\}$

4.	u	1	2	3	4	5	6
	$\mathbb{P}(U = u)$	$\frac{11}{36}$	$\frac{9}{36}$	$\frac{7}{36}$	$\frac{5}{36}$	$\frac{3}{36}$	$\frac{1}{36}$

5. $V(x_1, x_2) = \max\{x_1, x_2\}$ for $(x_1, x_2) \in S$. The set of values is $\{1, 2, 3, 4, 5, 6\}$

6.	v	1	2	3	4	5	6
	$\mathbb{P}(V = v)$	$\frac{1}{36}$	$\frac{3}{36}$	$\frac{5}{36}$	$\frac{7}{36}$	$\frac{9}{36}$	$\frac{11}{36}$

7. $\{(u, v) \in S : u \leq v\}$

$$8. \mathbb{P}(U = u, V = v) = \begin{cases} \frac{2}{36}, & u < v \\ \frac{1}{36}, & u = v \end{cases}$$

In the previous exercise, note that (U, V) could serve as the outcome vector for the experiment of rolling two standard, fair dice if we do not bother to distinguish the dice (so that we might as well record the smaller score first and then the larger score). Note that this random vector does *not* have a uniform distribution. On the other hand, we might have chosen at the beginning to just record the unordered set of scores and, as a modeling assumption, imposed the uniform distribution on the corresponding set of outcomes. Both models cannot be right, so which model (if either) describes real dice in the real world? It turns out that for real (fair) dice, the *ordered sequence* of scores is uniformly distributed, so real dice *behave* as distinct objects, whether you can tell them apart or not. In the early history of probability, gamblers sometimes got the wrong answers for events involving dice because they mistakenly applied the uniform distribution to the set of unordered scores. It's an important moral. If we are to impose the uniform distribution on a sample space, we need to make sure that it's the *right* sample space.

A pair of fair, standard dice are thrown repeatedly until the sum of the scores is either 5 or 7. Let A denote the event that the sum of the scores on the last throw is 5 rather than 7. Events of this type are important in the game of craps.

1. Suppose that we record the pair of scores on each throw. Give the set of outcomes S and express A as a subset of S .
2. Compute the probability of A in the setting of part (a).
3. Now suppose that we just record the pair of scores on the last throw. Give the set of outcomes T and express A as a subset of T .
4. Compute the probability of A in the setting of parts (c).

Answer

Let $D_5 = \{(1, 4), (2, 3), (3, 2), (4, 1)\}$ $D_7 = \{(1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1)\}$ $D = D_5 \cup D_7$,
 $C = \{1, 2, 3, 4, 5, 6\}^2 \setminus D$

1. $S = D \cup (C \times D) \cup (C^2 \times D) \cup \dots$, $A = D_5 \cup (C \times D_5) \cup (C^2 \times D_5) \cup \dots$
2. $\frac{2}{5}$
3. $T = D$, $A = D_5$
4. $\frac{2}{5}$

The previous problem shows the importance of defining the set of outcomes appropriately. Sometimes a clever choice of this set (and appropriate modeling assumptions) can turn a difficult problem into an easy one.

Sampling Models

Recall that many random experiments can be thought of as *sampling experiments*. For the general finite sampling model, we start with a population D with m (distinct) objects. We select a sample of n objects from the population, so that the sample space S is the set of possible samples. If we select a sample *at random* then the outcome \mathbf{X} (the random sample) is uniformly distributed on S :

$$\mathbb{P}(\mathbf{X} \in A) = \frac{\#(A)}{\#(S)}, \quad A \subseteq S \quad (2.3.26)$$

Recall from the section on Combinatorial Structures that there are four common types of sampling from a finite population, based on the criteria of *order* and *replacement*.

- If the sampling is with replacement and with regard to order, then the set of samples is the Cartesian power D^n . The number of samples is m^n .
- If the sampling is without replacement and with regard to order, then the set of samples is the set of all *permutations* of size n from D . The number of samples is $m^{(n)} = m(m-1) \cdots (m-n+1)$.
- If the sampling is without replacement and without regard to order, then the set of samples is the set of all *combinations* (or *subsets*) of size n from D . The number of samples is $\binom{m}{n} = m^{(n)}/n!$.
- If the sampling is with replacement and without regard to order, then the set of samples is the set of all *multisets* of size n from D . The number of samples is $\binom{m+n-1}{n}$.

If we sample with replacement, the sample size n can be any positive integer. If we sample without replacement, the sample size cannot exceed the population size, so we must have $n \in \{1, 2, \dots, m\}$.

The basic coin and dice experiments are examples of sampling *with* replacement. If we toss a fair coin n times and record the sequence of scores \mathbf{X} (where as usual, 0 denotes tails and 1 denotes heads), then \mathbf{X} is a random sample of size n chosen with order and with replacement from the population $\{0, 1\}$. Thus, \mathbf{X} is uniformly distributed on $\{0, 1\}^n$. If we throw n (distinct) standard fair dice and record the sequence of scores, then we generate a random sample \mathbf{X} of size n with order and with replacement from the population $\{1, 2, 3, 4, 5, 6\}$. Thus, \mathbf{X} is uniformly distributed on $\{1, 2, 3, 4, 5, 6\}^n$. Of an analogous result would hold for fair, k -sided dice.

Suppose that the sampling is without replacement (the most common case). If we record the *ordered* sample $\mathbf{X} = (X_1, X_2, \dots, X_n)$, then the *unordered* sample $\mathbf{W} = \{X_1, X_2, \dots\}$ is a random variable (that is, a function of \mathbf{X}). On the other hand, if we just record the unordered sample \mathbf{W} in the first place, then we cannot recover the ordered sample.

Suppose that \mathbf{X} is a random sample of size n chosen with order and without replacement from D , so that \mathbf{X} is uniformly distributed on the space of permutations of size n from D . Then \mathbf{W} , the unordered sample, is uniformly distributed on the space of combinations of size n from D . Thus, \mathbf{W} is also a random sample.

Proof

Let \mathbf{w} be a combination of size n from D . Then there are $n!$ permutations of the elements in \mathbf{w} . If A denotes this set of permutations, then $\mathbb{P}(\mathbf{W} = \mathbf{w}) = \mathbb{P}(\mathbf{X} \in A) = n! / m^{(n)} = 1 / \binom{m}{n}$.

The result in the last exercise does not hold if the sampling is with replacement (recall the [exercise above](#) and the discussion that follows). When sampling with replacement, there is no simple relationship between the number of ordered samples and the number of unordered samples.

Sampling From a Dichotomous Population

Suppose again that we have a population D with m (distinct) objects, but suppose now that each object is one of two types—either type 1 or type 0. Such populations are said to be *dichotomous*. Here are some specific examples:

- The population consists of persons, each either *male* or *female*.
- The population consists of voters, each either *democrat* or *republican*.
- The population consists of devices, each either *good* or *defective*.
- The population consists of balls, each either *red* or *green*.

Suppose that the population D has r type 1 objects and hence $m - r$ type 0 objects. Of course, we must have $r \in \{0, 1, \dots, m\}$. Now suppose that we select a sample of size n at random from the population. Note that this model has three parameters: the population size m , the number of type 1 objects in the population r , and the sample size n . Let Y denote the number of type 1 objects in the sample.

If the sampling is without replacement then

$$\mathbb{P}(Y = y) = \frac{\binom{r}{y} \binom{m-r}{n-y}}{\binom{m}{n}}, \quad y \in \{0, 1, \dots, n\} \quad (2.3.27)$$

Proof

Recall that the unordered sample is uniformly distributed over the set of combinations of size n chosen from the population. There are $\binom{m}{n}$ such samples. By the multiplication principle, the number of samples with exactly y type 1 objects and $n - y$ type 0 objects is $\binom{r}{y} \binom{m-r}{n-y}$.

In the previous exercise, random variable Y has the *hypergeometric distribution* with parameters m , r , and n . The hypergeometric distribution is studied in more detail in the chapter on Finite Sampling Models.

If the sampling is with replacement then

$$\mathbb{P}(Y = y) = \binom{n}{y} \frac{r^y (m-r)^{n-y}}{m^n} = \binom{n}{y} \left(\frac{r}{m}\right)^y \left(1 - \frac{r}{m}\right)^{n-y}, \quad y \in \{0, 1, \dots, n\} \quad (2.3.28)$$

Proof

Recall that the ordered sample is uniformly distributed over the set D^n and there are m^n elements in this set. To count the number of samples with exactly y type 1 objects, we use a three-step procedure: first, select the coordinates for the type 1 objects; there are $\binom{n}{y}$ choices. Next select the y type 1 objects for these coordinates; there are r^y choices. Finally select the $n - y$ type 0 objects for the remaining coordinates of the sample; there are $(m - r)^{n-y}$ choices. The result now follows from the multiplication principle.

In the last exercise, random variable Y has the *binomial distribution* with parameters n and $p = \frac{r}{m}$. The binomial distribution is studied in more detail in the chapter on Bernoulli Trials.

Suppose that a group of voters consists of 40 democrats and 30 republicans. A sample 10 voters is chosen at random. Find the probability that the sample contains at least 4 democrats and at least 4 republicans, each of the following cases:

1. The sampling is without replacement.
2. The sampling is with replacement.

Answer

1. $\frac{1\,391\,351\,589}{2\,176\,695\,188} \approx 0.6382$
2. $\frac{24\,509\,952}{40\,353\,607} \approx 0.6074$

Look for other specialized sampling situations in the exercises below.

Urn Models

Drawing balls from an urn is a standard metaphor in probability for sampling from a finite population.

Consider an urn with 30 balls; 10 are red and 20 are green. A sample of 5 balls is chosen at random, without replacement. Let Y denote the number of red balls in the sample. Explicitly compute $\mathbb{P}(Y = y)$ for each $y \in \{0, 1, 2, 3, 4, 5\}$.

answer

y	0	1	2	3	4	5
$\mathbb{P}(Y = y)$	$\frac{2584}{23751}$	$\frac{8075}{23751}$	$\frac{8550}{23751}$	$\frac{3800}{23751}$	$\frac{700}{23751}$	$\frac{42}{23751}$

In the simulation of the ball and urn experiment, select 30 balls with 10 red and 20 green, sample size 5, and sampling without replacement. Run the experiment 1000 times and compare the empirical probabilities with the true probabilities that you computed in the previous exercise.

Consider again an urn with 30 balls; 10 are red and 20 are green. A sample of 5 balls is chosen at random, with replacement. Let Y denote the number of red balls in the sample. Explicitly compute $\mathbb{P}(Y = y)$ for each $y \in \{0, 1, 2, 3, 4, 5\}$.

Answer

y	0	1	2	3	4	5
$\mathbb{P}(Y = y)$	$\frac{32}{243}$	$\frac{80}{243}$	$\frac{80}{243}$	$\frac{40}{243}$	$\frac{10}{243}$	$\frac{1}{243}$

In the simulation of the ball and urn experiment, select 30 balls with 10 red and 20 green, sample size 5, and sampling with replacement. Run the experiment 1000 times and compare the empirical probabilities with the true probabilities that you computed in the previous exercise.

An urn contains 15 balls: 6 are red, 5 are green, and 4 are blue. Three balls are chosen at random, without replacement.

1. Find the probability that the chosen balls are all the same color.
2. Find the probability that the chosen balls are all different colors.

Answer

1. $\frac{34}{455}$
2. $\frac{120}{455}$

Suppose again that an urn contains 15 balls: 6 are red, 5 are green, and 4 are blue. Three balls are chosen at random, with replacement.

1. Find the probability that the chosen balls are all the same color.
2. Find the probability that the chosen balls are all different colors.

Answer

1. $\frac{405}{3375}$
2. $\frac{720}{3375}$

Cards

Recall that a standard *card deck* can be modeled by the product set

$$D = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, j, q, k\} \times \{\clubsuit, \diamondsuit, \heartsuit, \spadesuit\} \quad (2.3.29)$$

where the first coordinate encodes the *denomination* or *kind* (ace, 2–10, jack, queen, king) and where the second coordinate encodes the *suit* (clubs, diamonds, hearts, spades). Sometimes we represent a card as a *string* rather than an ordered pair (for example $q\heartsuit$ for the queen of hearts).

Card games involve choosing a [random sample](#) without replacement from the deck D , which plays the role of the population. Thus, the basic *card experiment* consists of dealing n cards from a standard deck without replacement; in this special context, the sample of cards is often referred to as a *hand*. Just as in the general sampling model, if we record the *ordered* hand $\mathbf{X} = (X_1, X_2, \dots, X_n)$, then the *unordered* hand $\mathbf{W} = \{X_1, X_2, \dots, X_n\}$ is a random variable (that is, a function of \mathbf{X}). On the other hand, if we just record the unordered hand \mathbf{W} in the first place, then we cannot recover the ordered hand. Finally, recall that $n = 5$ is the *poker experiment* and $n = 13$ is the *bridge experiment*. The game of poker is treated in more detail in the chapter on Games of Chance. By the way, it takes about 7 standard riffle shuffles to randomize a deck of cards.

Suppose that 2 cards are dealt from a well-shuffled deck and the sequence of cards is recorded. For $i \in \{1, 2\}$, let H_i denote the event that card i is a heart. Find the probability of each of the following events.

1. H_1

2. $H_1 \cap H_2$
3. $H_2 \setminus H_1$
4. H_2
5. $H_1 \setminus H_2$
6. $H_1 \cup H_2$

Answer

1. $\frac{1}{4}$
2. $\frac{1}{17}$
3. $\frac{13}{68}$
4. $\frac{1}{4}$
5. $\frac{13}{68}$
6. $\frac{15}{34}$

Think about the results in the previous exercise, and suppose that we continue dealing cards. Note that in computing the probability of H_i , you could conceptually reduce the experiment to dealing a single card. Note also that the probabilities do not depend on the order in which the cards are dealt. For example, the probability of an event involving the 1st, 2nd and 3rd cards is the same as the probability of the corresponding event involving the 25th, 17th, and 40th cards. Technically, the cards are *exchangeable*. Here's another way to think of this concept: Suppose that the cards are dealt onto a table in some pattern, but you are not allowed to view the process. Then no experiment that you can devise will give you any information about the order in which the cards were dealt.

In the card experiment, set $n = 2$. Run the experiment 100 times and compute the empirical probability of each event in the previous exercise

In the poker experiment, find the probability of each of the following events:

1. The hand is a *full house* (3 cards of one kind and 2 cards of another kind).
2. The hand has *four of a kind* (4 cards of one kind and 1 of another kind).
3. The cards are all in the same suit (thus, the hand is either a *flush* or a *straight flush*).

Answer

1. $\frac{3744}{2\,598\,960} \approx 0.001441$
2. $\frac{624}{2\,598\,960} \approx 0.000240$
3. $\frac{5148}{2\,598\,960} \approx 0.001981$

Run the poker experiment 10000 times, updating every 10 runs. Compute the empirical probability of each event in the previous problem.

Find the probability that a bridge hand will contain no *honor cards* that is, no cards of denomination 10, jack, queen, king, or ace. Such a hand is called a *Yarborough*, in honor of the second Earl of Yarborough.

Answer

$$\frac{347\,373\,600}{635\,013\,559\,600} \approx 0.000547$$

Find the probability that a bridge hand will contain

1. Exactly 4 hearts.
2. Exactly 4 hearts and 3 spades.
3. Exactly 4 hearts, 3 spades, and 2 clubs.

Answer

1. $\frac{151\,519\,319\,380}{635\,013\,559\,600} \approx 0.2386$
2. $\frac{47\,079\,732\,700}{635\,013\,559\,600} \approx 0.0741$
3. $\frac{11\,404\,407\,300}{635\,013\,559\,600} \approx 0.0179$

A card hand that contains no cards in a particular suit is said to be *void* in that suit. Use the [inclusion-exclusion rule](#) to find the probability of each of the following events:

1. A poker hand is void in at least one suit.
2. A bridge hand is void in at least one suit.

Answer

1. $\frac{1\,913\,496}{2\,598\,960} \approx 0.7363$
2. $\frac{32\,427\,298\,180}{635\,013\,559\,600} \approx 0.051$

Birthdays

The following problem is known as the *birthday problem*, and is famous because the results are rather surprising at first.

Suppose that n persons are selected and their birthdays recorded (we will ignore leap years). Let A denote the event that the birthdays are distinct, so that A^c is the event that there is at least one duplication in the birthdays.

1. Define an appropriate sample space and probability measure. State the assumptions you are making.
2. Find $P(A)$ and $\mathbb{P}(A^c)$ in terms of the parameter n .
3. Explicitly compute $P(A)$ and $P(A^c)$ for $n \in \{10, 20, 30, 40, 50\}$

Answer

1. The set of outcomes is $S = D^n$ where D is the set of days of the year. We assume that the outcomes are equally likely, so that S has the uniform distribution.
2. $\#(A) = 365^{(n)}$, so $\mathbb{P}(A) = 365^{(n)}/365^n$ and $\mathbb{P}(A^c) = 1 - 365^{(n)}/365^n$

3. n	$\mathbb{P}(A)$	$\mathbb{P}(A^c)$
10	0.883	0.117
20	0.589	0.411
30	0.294	0.706
40	0.109	0.891
50	0.006	0.994

The small value of $\mathbb{P}(A)$ for relatively small sample sizes n is striking, but is due mathematically to the fact that 365^n grows much faster than $365^{(n)}$ as n increases. The birthday problem is treated in more generality in the chapter on Finite Sampling Models.

Suppose that 4 persons are selected and their birth *months* recorded. Assuming an appropriate uniform distribution, find the probability that the months are distinct.

Answer

$$\frac{11880}{20736} \approx 0.573$$

Continuous Uniform Distributions

Recall that in Buffon's coin experiment, a coin with radius $r \leq \frac{1}{2}$ is tossed “randomly” on a floor with square tiles of side length 1, and the coordinates (X, Y) of the center of the coin are recorded, relative to axes through the center of the square in which the coin lands (with the axes parallel to the sides of the square, of course). Let A denote the event that the coin does not touch the sides of the square.

1. Define the set of outcomes S mathematically and sketch S .
2. Argue that (X, Y) is uniformly distributed on S .
3. Express A in terms of the outcome variables (X, Y) and sketch A .
4. Find $\mathbb{P}(A)$.

5. Find $\mathbb{P}(A^c)$.

Answer

1. $S = [-\frac{1}{2}, \frac{1}{2}]^2$
2. Since the coin is tossed “randomly”, no region of S should be preferred over any other.
3. $\{r - \frac{1}{2} < X < \frac{1}{2} - r, r - \frac{1}{2} < Y < \frac{1}{2} - r\}$
4. $\mathbb{P}(A) = (1 - 2r)^2$
5. $\mathbb{P}(A^c) = 1 - (1 - 2r)^2$

In Buffon's coin experiment, set $r = 0.2$. Run the experiment 100 times and compute the empirical probability of each event in the previous exercise.

A point (X, Y) is chosen at random in the circular region $S \subset \mathbb{R}^2$ of radius 1, centered at the origin. Let A denote the event that the point is in the inscribed square region centered at the origin, with sides parallel to the coordinate axes, and let B denote the event that the point is in the inscribed square with vertices $(\pm 1, 0)$, $(0, \pm 1)$. Sketch each of the following events as a subset of S , and find the probability of the event.

1. A
2. B
3. $A \cap B^c$
4. $B \cap A^c$
5. $A \cap B$
6. $A \cup B$

Answer

1. $2/\pi$
2. $2/\pi$
3. $(6 - 4\sqrt{2})/\pi$
4. $(6 - 4\sqrt{2})/\pi$
5. $4(\sqrt{2} - 1)/\pi$
6. $4(2 - \sqrt{2})/\pi$

Suppose a point (X, Y) is chosen at random in the circular region $S \subseteq \mathbb{R}^2$ of radius 12, centered at the origin. Let R denote the distance from the origin to the point. Sketch each of the following events as a subset of S , and compute the probability of the event. Is R uniformly distributed on the interval $[0, 12]$?

1. $\{R \leq 3\}$
2. $\{3 < R \leq 6\}$
3. $\{6 < R \leq 9\}$
4. $\{9 < R \leq 12\}$

Answer

No, R is not uniformly distributed on $[0, 12]$.

1. $\frac{1}{16}$
2. $\frac{3}{16}$
3. $\frac{5}{16}$
4. $\frac{7}{16}$

In the simple probability experiment, points are generated according to the uniform distribution on a rectangle. Move and resize the events A and B and note how the probabilities of the various events change. Create each of the following configurations. In each case, run the experiment 1000 times and compare the relative frequencies of the events to the probabilities of the events.

1. A and B in general position

2. A and B disjoint
3. $A \subseteq B$
4. $B \subseteq A$

Genetics

Please refer to the discussion of genetics in the section on random experiments if you need to review some of the definitions in this subsection.

Recall first that the *ABO blood type* in humans is determined by three alleles: a , b , and o . Furthermore, a and b are co-dominant and o is recessive. Suppose that the probability distribution for the set of blood genotypes in a certain population is given in the following table:

Genotype	aa	ab	ao	bb	bo	oo
Probability	0.050	0.038	0.310	0.007	0.116	0.479

A person is chosen at random from the population. Let A , B , AB , and O be the events that the person is type A , type B , type AB , and type O respectively. Let H be the event that the person is homozygous and D the event that the person has an o allele. Find the probability of the following events:

1. A
2. B
3. AB
4. O
5. H
6. D
7. $H \cup D$
8. D^c

Answer

1. 0.360
2. 0.123
3. 0.038
4. 0.479
5. 0.536
6. 0.905
7. 0.962
8. 0.095

Suppose next that pod color in certain type of pea plant is determined by a gene with two alleles: g for green and y for yellow, and that g is dominant.

Let G be the event that a child plant has green pods. Find $\mathbb{P}(G)$ in each of the following cases:

1. At least one parent is type gg .
2. Both parents are type yy .
3. Both parents are type gy .
4. One parent is type yy and the other is type gy .

Answer

1. 1
2. 0
3. $\frac{3}{4}$
4. $\frac{1}{2}$

Next consider a sex-linked hereditary disorder in humans (such as colorblindness or hemophilia). Let h denote the healthy allele and d the defective allele for the gene linked to the disorder. Recall that d is recessive for women.

Let B be the event that a son has the disorder, C the event that a daughter is a healthy carrier, and D the event that a daughter has the disease. Find $\mathbb{P}(B)$, $\mathbb{P}(C)$ and $\mathbb{P}(D)$ in each of the following cases:

1. The mother and father are normal.
2. The mother is a healthy carrier and the father is normal.
3. The mother is normal and the father has the disorder.
4. The mother is a healthy carrier and the father has the disorder.
5. The mother has the disorder and the father is normal.
6. The mother and father both have the disorder.

Answer

1. 0, 0, 0
2. $1/2$, 0, $1/2$
3. 0, $1/2$, 0
4. $1/2$, $1/2$, $1/2$
5. 1, $1/2$, 0
6. 1, 0, 1

From this exercise, note that transmission of the disorder to a daughter can only occur if the mother is at least a carrier and the father has the disorder. In ordinary large populations, this is a unusual intersection of events, and thus sex-linked hereditary disorders are typically much less common in women than in men. In brief, women are protected by the extra X chromosome.

Radioactive Emissions

Suppose that T denotes the time between emissions (in milliseconds) for a certain type of radioactive material, and that T has the following probability distribution, defined for measurable $A \subseteq [0, \infty)$ by

$$\mathbb{P}(T \in A) = \int_A e^{-t} dt \quad (2.3.30)$$

1. Show that this really does define a probability distribution.
2. Find $\mathbb{P}(T > 3)$.
3. Find $\mathbb{P}(2 < T < 4)$.

Answer

1. Note that $\int_0^\infty e^{-t} dt = 1$
2. e^{-3}
3. $e^{-2} - e^{-4}$

Suppose that N denotes the number of emissions in a one millisecond interval for a certain type of radioactive material, and that N has the following probability distribution:

$$\mathbb{P}(N \in A) = \sum_{n \in A} \frac{e^{-1}}{n!}, \quad A \subseteq \mathbb{N} \quad (2.3.31)$$

1. Show that this really does define a probability distribution.
2. Find $\mathbb{P}(N \geq 3)$.
3. Find $\mathbb{P}(2 \leq N \leq 4)$.

Answer

1. Note that $\sum_{n=0}^\infty \frac{e^{-1}}{n!} = 1$
2. $1 - \frac{5}{2}e^{-1}$
3. $\frac{17}{24}e^{-1}$

The probability distribution that governs the [time between emissions](#) is a special case of the *exponential distribution*, while the probability distribution that governs the [number of emissions](#) is a special case of the *Poisson distribution*, named for Simeon Poisson. The exponential distribution and the Poisson distribution are studied in more detail in the chapter on the Poisson process.

Matching

Suppose that at an absented-minded secretary prepares 4 letters and matching envelopes to send to 4 different persons, but then stuffs the letters into the envelopes randomly. Find the probability of the event A that at least one letter is in the proper envelope.

Solution

Note first that the set of outcomes S can be taken to be the set of permutations of $\{1, 2, 3, 4\}$. For $x \in S$, x_i is the number of the envelope containing the i th letter. Clearly S should be given the uniform probability distribution. Next note that $A = A_1 \cup A_2 \cup A_3 \cup A_4$ where A_i is the event that the i th letter is inserted into the i th envelope. Using the inclusion-exclusion rule gives $\mathbb{P}(A) = \frac{5}{8}$.

This exercise is an example of the *matching problem*, originally formulated and studied by Pierre Remond Montmort. A complete analysis of the matching problem is given in the chapter on Finite Sampling Models.

In the simulation of the matching experiment select $n = 4$. Run the experiment 1000 times and compute the relative frequency of the event that at least one match occurs.

Data Analysis Exercises

For the M&M data set, let R denote the event that a bag has at least 10 red candies, T the event that a bag has at least 57 candies total, and W the event that a bag weighs at least 50 grams. Find the empirical probability the following events:

1. R
2. T
3. W
4. $R \cap T$
5. $T \setminus W$

Answer

1. $\frac{13}{30}$
2. $\frac{19}{30}$
3. $\frac{9}{30}$
4. $\frac{9}{30}$
5. $\frac{11}{30}$

For the cicada data, let W denote the event that a cicada weighs at least 0.20 grams, F the event that a cicada is female, and T the event that a cicada is type tredecia. Find the empirical probability of each of the following:

1. W
2. F
3. T
4. $W \cap F$
5. $F \cup T \cup W$

Answer

1. $\frac{37}{104}$
2. $\frac{59}{104}$
3. $\frac{44}{104}$
4. $\frac{34}{104}$
5. $\frac{85}{104}$

This page titled [2.3: Probability Measures](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

2.4: Conditional Probability

The purpose of this section is to study how probabilities are updated in light of new information, clearly an absolutely essential topic. If you are a new student of probability, you may want to skip the technical details.

Definitions and Interpretations

The Basic Definition

As usual, we start with a random experiment modeled by a probability space $(S, \mathcal{S}, \mathbb{P})$. Thus, S is the set of outcomes, \mathcal{S} the collection of events, and \mathbb{P} the probability measure on the sample space (S, \mathcal{S}) . Suppose now that we know that an event B has occurred. In general, this information should clearly alter the probabilities that we assign to other events. In particular, if A is another event then A occurs if and only if A and B occur; effectively, the sample space has been reduced to B . Thus, the probability of A , given that we know B has occurred, should be proportional to $\mathbb{P}(A \cap B)$.

Figure 2.4.1: Events A and B

However, conditional probability, given that B has occurred, should still be a probability measure, that is, it must satisfy the axioms of probability. This forces the proportionality constant to be $1/\mathbb{P}(B)$. Thus, we are led inexorably to the following definition:

Let A and B be events with $\mathbb{P}(B) > 0$. The *conditional probability* of A given B is defined to be

$$\mathbb{P}(A | B) = \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)} \quad (2.4.1)$$

The Law of Large Numbers

The [definition](#) above was based on the axiomatic definition of probability. Let's explore the idea of conditional probability from the less formal and more intuitive notion of relative frequency (the law of large numbers). Thus, suppose that we run the experiment repeatedly. For $n \in \mathbb{N}_+$ and an event E , let $N_n(E)$ denote the number of times E occurs (the frequency of E) in the first n runs. Note that $N_n(E)$ is a random variable in the compound experiment that consists of replicating the original experiment. In particular, its value is unknown until we actually run the experiment n times.

If $N_n(B)$ is large, the conditional probability that A has occurred, given that B has occurred, should be close to the *conditional relative frequency* of A given B , namely the relative frequency of A for the runs on which B occurred: $N_n(A \cap B)/N_n(B)$. But note that

$$\frac{N_n(A \cap B)}{N_n(B)} = \frac{N_n(A \cap B)/n}{N_n(B)/n} \quad (2.4.2)$$

The numerator and denominator of the main fraction on the right are the relative frequencies of $A \cap B$ and B , respectively. So by the law of large numbers again, $N_n(A \cap B)/n \rightarrow \mathbb{P}(A \cap B)$ as $n \rightarrow \infty$ and $N_n(B)/n \rightarrow \mathbb{P}(B)$ as $n \rightarrow \infty$. Hence

$$\frac{N_n(A \cap B)}{N_n(B)} \rightarrow \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)} \text{ as } n \rightarrow \infty \quad (2.4.3)$$

and we are led again to the [definition](#) above.

In some cases, conditional probabilities can be computed *directly*, by effectively reducing the sample space to the given event. In other cases, the formula in the mathematical definition is better. In some cases, conditional probabilities are known from modeling assumptions, and then are used to compute other probabilities. We will see examples of all of these situations in the [computational exercises](#) below.

It's very important that you not confuse $\mathbb{P}(A | B)$, the probability of A given B , with $\mathbb{P}(B | A)$, the probability of B given A . Making that mistake is known as the *fallacy of the transposed conditional*. (How embarrassing!)

Conditional Distributions

Suppose that X is a random variable for the experiment with values in T . Mathematically, X is a function from S into T , and $\{X \in A\}$ denotes the event $\{s \in S : X(s) \in A\}$ for $A \subseteq T$. Intuitively, X is a variable of interest in the experiment, and every meaningful statement about X defines an event. Recall that the probability distribution of X is the probability measure on T given by

$$A \mapsto \mathbb{P}(X \in A), \quad A \subseteq T \quad (2.4.4)$$

This has a natural extension to a conditional distribution, given an event.

If B is an event with $\mathbb{P}(B) > 0$, then the *conditional distribution of X given B* is the probability measure on T given by

$$A \mapsto \mathbb{P}(X \in A \mid B), \quad A \subseteq T \quad (2.4.5)$$

Details

Recall that T will come with a σ -algebra of admissible subsets so that (T, \mathcal{T}) is a measurable space, just like the sample space (S, \mathcal{S}) . Random variable X is required to be measurable as a function from S into T . This ensures that $\{X \in A\}$ is a valid event for each $A \in \mathcal{T}$, so that the definition makes sense.

Basic Theory

Preliminary Results

Our first result is of fundamental importance, and indeed was a crucial part of the argument for the definition of conditional probability.

Suppose again that B is an event with $\mathbb{P}(B) > 0$. Then $A \mapsto \mathbb{P}(A \mid B)$ is a probability measure on S .

Proof

Clearly $\mathbb{P}(A \mid B) \geq 0$ for every event A , and $\mathbb{P}(S \mid B) = 1$. Thus, suppose that $\{A_i : i \in I\}$ is a countable collection of pairwise disjoint events. Then

$$\mathbb{P}\left(\bigcup_{i \in I} A_i \mid B\right) = \frac{1}{\mathbb{P}(B)} \mathbb{P}\left[\left(\bigcup_{i \in I} A_i\right) \cap B\right] = \frac{1}{\mathbb{P}(B)} \mathbb{P}\left(\bigcup_{i \in I} (A_i \cap B)\right) \quad (2.4.6)$$

But the collection of events $\{A_i \cap B : i \in I\}$ is also pairwise disjoint, so

$$\mathbb{P}\left(\bigcup_{i \in I} A_i \mid B\right) = \frac{1}{\mathbb{P}(B)} \sum_{i \in I} \mathbb{P}(A_i \cap B) = \sum_{i \in I} \frac{\mathbb{P}(A_i \cap B)}{\mathbb{P}(B)} = \sum_{i \in I} \mathbb{P}(A_i \mid B) \quad (2.4.7)$$

It's hard to overstate the importance of the [last result](#) because this theorem means that any result that holds for probability measures in general holds for conditional probability, as long as the conditioning event remains fixed. In particular the basic probability rules in the section on Probability Measure have analogs for conditional probability. To give two examples,

$$\mathbb{P}(A^c \mid B) = 1 - \mathbb{P}(A \mid B) \quad (2.4.8)$$

$$\mathbb{P}(A_1 \cup A_2 \mid B) = \mathbb{P}(A_1 \mid B) + \mathbb{P}(A_2 \mid B) - \mathbb{P}(A_1 \cap A_2 \mid B) \quad (2.4.9)$$

By the same token, it follows that the conditional distribution of a random variable with values in T , given in [above](#), really does define a probability distribution on T . No further proof is necessary. Our next results are very simple.

Suppose that A and B are events with $\mathbb{P}(B) > 0$.

1. If $B \subseteq A$ then $\mathbb{P}(A \mid B) = 1$.
2. If $A \subseteq B$ then $\mathbb{P}(A \mid B) = \mathbb{P}(A)/\mathbb{P}(B)$.
3. If A and B are disjoint then $\mathbb{P}(A \mid B) = 0$.

Proof

These results follow directly from the definition of conditional probability. In part (a), note that $A \cap B = B$. In part (b) note that $A \cap B = A$. In part (c) note that $A \cap B = \emptyset$.

Parts (a) and (c) certainly make sense. Suppose that we know that event B has occurred. If $B \subseteq A$ then A becomes a certain event. If $A \cap B = \emptyset$ then A becomes an impossible event. A conditional probability can be computed relative to a probability measure that is itself a conditional probability measure. The following result is a consistency condition.

Suppose that A , B , and C are events with $\mathbb{P}(B \cap C) > 0$. The probability of A given B , relative to $\mathbb{P}(\cdot | C)$, is the same as the probability of A given B and C (relative to \mathbb{P}). That is,

$$\frac{\mathbb{P}(A \cap B | C)}{\mathbb{P}(B | C)} = \mathbb{P}(A | B \cap C) \quad (2.4.10)$$

Proof

From the definition,

$$\frac{\mathbb{P}(A \cap B | C)}{\mathbb{P}(B | C)} = \frac{\mathbb{P}(A \cap B \cap C) / \mathbb{P}(C)}{\mathbb{P}(B \cap C) / \mathbb{P}(C)} = \frac{\mathbb{P}(A \cap B \cap C)}{\mathbb{P}(B \cap C)} = \mathbb{P}(A | B \cap C) \quad (2.4.11)$$

Correlation

Our next discussion concerns an important concept that deals with how two events are related, in a probabilistic sense.

Suppose that A and B are events with $\mathbb{P}(A) > 0$ and $\mathbb{P}(B) > 0$.

1. $\mathbb{P}(A | B) > \mathbb{P}(A)$ if and only if $\mathbb{P}(B | A) > \mathbb{P}(B)$ if and only if $\mathbb{P}(A \cap B) > \mathbb{P}(A)\mathbb{P}(B)$. In this case, A and B are *positively correlated*.
2. $\mathbb{P}(A | B) < \mathbb{P}(A)$ if and only if $\mathbb{P}(B | A) < \mathbb{P}(B)$ if and only if $\mathbb{P}(A \cap B) < \mathbb{P}(A)\mathbb{P}(B)$. In this case, A and B are *negatively correlated*.
3. $\mathbb{P}(A | B) = \mathbb{P}(A)$ if and only if $\mathbb{P}(B | A) = \mathbb{P}(B)$ if and only if $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B)$. In this case, A and B are *uncorrelated or independent*.

Proof

These properties follow directly from the definition of conditional probability and simple algebra. Recall that multiplying or dividing an inequality by a positive number preserves the inequality.

Intuitively, if A and B are positively correlated, then the occurrence of either event means that the other event is more likely. If A and B are negatively correlated, then the occurrence of either event means that the other event is less likely. If A and B are uncorrelated, then the occurrence of either event does not change the probability of the other event. Independence is a fundamental concept that can be extended to more than two events and to random variables; these generalizations are studied in the next section on Independence. A much more general version of correlation, for random variables, is explored in the section on Covariance and Correlation in the chapter on Expected Value.

Suppose that A and B are events. Note from (4) that if $A \subseteq B$ or $B \subseteq A$ then A and B are positively correlated. If A and B are disjoint then A and B are negatively correlated.

Suppose that A and B are events in a random experiment.

1. A and B have the same correlation (positive, negative, or zero) as A^c and B^c .
2. A and B have the opposite correlation as A and B^c (that is, positive-negative, negative-positive, or 0-0).

Proof

1. Using DeMorgan's law and the complement law.

$$\mathbb{P}(A^c \cap B^c) - \mathbb{P}(A^c)\mathbb{P}(B^c) = \mathbb{P}[(A \cup B)^c] - \mathbb{P}(A^c)\mathbb{P}(B^c) = [1 - \mathbb{P}(A \cup B)] - [1 - \mathbb{P}(A)][1 - \mathbb{P}(B)] \quad (2.4.12)$$

Using the inclusion-exclusion law and algebra,

$$\mathbb{P}(A^c \cap B^c) - \mathbb{P}(A^c)\mathbb{P}(B^c) = \mathbb{P}(A \cap B) - \mathbb{P}(A)\mathbb{P}(B) \quad (2.4.13)$$

2. Using the difference rule and the complement law:

$$\mathbb{P}(A \cap B^c) - \mathbb{P}(A)\mathbb{P}(B^c) = \mathbb{P}(A) - \mathbb{P}(A \cap B) - \mathbb{P}(A)[1 - \mathbb{P}(B)] = -[\mathbb{P}(A \cap B) - \mathbb{P}(A)\mathbb{P}(B)] \quad (2.4.14)$$

The Multiplication Rule

Sometimes conditional probabilities are known and can be used to find the probabilities of other events. Note first that if A and B are events with positive probability, then by the very definition of conditional probability,

$$\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B | A) = \mathbb{P}(B)\mathbb{P}(A | B) \quad (2.4.15)$$

The following generalization is known as the *multiplication rule* of probability. As usual, we assume that any event conditioned on has positive probability.

Suppose that (A_1, A_2, \dots, A_n) is a sequence of events. Then

$$\mathbb{P}(A_1 \cap A_2 \cap \dots \cap A_n) = \mathbb{P}(A_1)\mathbb{P}(A_2 | A_1)\mathbb{P}(A_3 | A_1 \cap A_2) \dots \mathbb{P}(A_n | A_1 \cap A_2 \cap \dots \cap A_{n-1}) \quad (2.4.16)$$

Proof

The product on the right is a collapsing product in which only the probability of the intersection of all n events survives. The product of the first two factors is $\mathbb{P}(A_1 \cap A_2)$, and hence the product of the first three factors is $\mathbb{P}(A_1 \cap A_2 \cap A_3)$, and so forth. The proof can be made more rigorous by induction on n .

The multiplication rule is particularly useful for experiments that consist of dependent stages, where A_i is an event in stage i . Compare the multiplication rule of probability with the multiplication rule of combinatorics.

As with any other result, the multiplication rule can be applied to a conditional probability measure. In the context above, if E is another event, then

$$\mathbb{P}(A_1 \cap A_2 \cap \dots \cap A_n | E) = \mathbb{P}(A_1 | E)\mathbb{P}(A_2 | A_1 \cap E)\mathbb{P}(A_3 | A_1 \cap A_2 \cap E) \dots \mathbb{P}(A_n | A_1 \cap A_2 \cap \dots \cap A_{n-1} \cap E) \quad (2.4.17)$$

Conditioning and Bayes' Theorem

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ is a countable collection of events that partition the sample space S , and that $\mathbb{P}(A_i) > 0$ for each $i \in I$.

Figure 2.4.2: A partition of S induces a partition of B .

The following theorem is known as the *law of total probability*.

If B is an event then

$$\mathbb{P}(B) = \sum_{i \in I} \mathbb{P}(A_i)\mathbb{P}(B | A_i) \quad (2.4.18)$$

Proof

Recall that $\{A_i \cap B : i \in I\}$ is a partition of B . Hence

$$\mathbb{P}(B) = \sum_{i \in I} \mathbb{P}(A_i \cap B) = \sum_{i \in I} \mathbb{P}(A_i)\mathbb{P}(B | A_i) \quad (2.4.19)$$

The following theorem is known as *Bayes' Theorem*, named after Thomas Bayes:

If B is an event then

$$\mathbb{P}(A_j | B) = \frac{\mathbb{P}(A_j)\mathbb{P}(B | A_j)}{\sum_{i \in I} \mathbb{P}(A_i)\mathbb{P}(B | A_i)}, \quad j \in I \quad (2.4.20)$$

Proof

Again the numerator is $\mathbb{P}(A_j \cap B)$ while the denominator is $\mathbb{P}(B)$ by the [law of total probability](#).

These two theorems are most useful, of course, when we know $\mathbb{P}(A_i)$ and $\mathbb{P}(B | A_i)$ for each $i \in I$. When we compute the probability of $\mathbb{P}(B)$ by the [law of total probability](#), we say that we are *conditioning* on the partition \mathcal{A} . Note that we can think of the sum as a *weighted average* of the conditional probabilities $\mathbb{P}(B | A_i)$ over $i \in I$, where $\mathbb{P}(A_i)$, $i \in I$ are the weight factors. In the context of [Bayes theorem](#), $\mathbb{P}(A_j)$ is the *prior probability* of A_j and $\mathbb{P}(A_j | B)$ is the *posterior probability* of A_j for $j \in I$. We will study more general versions of conditioning and Bayes theorem in the section on Discrete Distributions in the chapter on Distributions, and again in the section on Conditional Expected Value in the chapter on Expected Value.

Once again, the law of total probability and Bayes' theorem can be applied to a conditional probability measure. So, if E is another event with $\mathbb{P}(A_i \cap E) > 0$ for $i \in I$ then

$$\mathbb{P}(B | E) = \sum_{i \in I} \mathbb{P}(A_i | E) \mathbb{P}(B | A_i \cap E) \quad (2.4.21)$$

$$\mathbb{P}(A_j | B \cap E) = \frac{\mathbb{P}(A_j | E) \mathbb{P}(B | A_j \cap E)}{\sum_{i \in I} \mathbb{P}(A_i \cap E) \mathbb{P}(B | A_i \cap E)}, \quad j \in I \quad (2.4.22)$$

Examples and Applications

Basic Rules

Suppose that A and B are events in an experiment with $\mathbb{P}(A) = \frac{1}{3}$, $\mathbb{P}(B) = \frac{1}{4}$, $\mathbb{P}(A \cap B) = \frac{1}{10}$. Find each of the following:

1. $\mathbb{P}(A | B)$
2. $\mathbb{P}(B | A)$
3. $\mathbb{P}(A^c | B)$
4. $\mathbb{P}(B^c | A)$
5. $\mathbb{P}(A^c | B^c)$

Answer

1. $\frac{2}{5}$
2. $\frac{3}{10}$
3. $\frac{3}{5}$
4. $\frac{7}{10}$
5. $\frac{31}{45}$

Suppose that A , B , and C are events in a random experiment with $\mathbb{P}(A | C) = \frac{1}{2}$, $\mathbb{P}(B | C) = \frac{1}{3}$, and $\mathbb{P}(A \cap B | C) = \frac{1}{4}$. Find each of the following:

1. $\mathbb{P}(B \setminus A | C)$
2. $\mathbb{P}(A \cup B | C)$
3. $\mathbb{P}(A^c \cap B^c | C)$
4. $\mathbb{P}(A^c \cup B^c | C)$
5. $\mathbb{P}(A^c \cup B | C)$
6. $\mathbb{P}(A | B \cap C)$

Answer

1. $\frac{1}{12}$
2. $\frac{7}{12}$
3. $\frac{5}{12}$
4. $\frac{3}{4}$
5. $\frac{3}{4}$
6. $\frac{3}{4}$

Suppose that A and B are events in a random experiment with $\mathbb{P}(A) = \frac{1}{2}$, $\mathbb{P}(B) = \frac{1}{3}$, and $\mathbb{P}(A | B) = \frac{3}{4}$.

1. Find $\mathbb{P}(A \cap B)$
2. Find $\mathbb{P}(A \cup B)$

3. Find $\mathbb{P}(B \cup A^c)$
4. Find $\mathbb{P}(B | A)$
5. Are A and B positively correlated, negatively correlated, or independent?

Answer

1. $\frac{1}{4}$
2. $\frac{7}{12}$
3. $\frac{3}{4}$
4. $\frac{1}{2}$
5. positively correlated.

Open the conditional probability experiment.

1. Given $\mathbb{P}(A)$, $\mathbb{P}(B)$, and $\mathbb{P}(A \cap B)$, in the table, verify all of the other probabilities in the table.
2. Run the experiment 1000 times and compare the probabilities with the relative frequencies.

Simple Populations

In a certain population, 30% of the persons smoke cigarettes and 8% have COPD (*Chronic Obstructive Pulmonary Disease*). Moreover, 12% of the persons who smoke have COPD.

1. What percentage of the population smoke and have COPD?
2. What percentage of the population with COPD also smoke?
3. Are smoking and COPD positively correlated, negatively correlated, or independent?

Answer

1. 3.6%
2. 45%
3. positively correlated.

A company has 200 employees: 120 are women and 80 are men. Of the 120 female employees, 30 are classified as managers, while 20 of the 80 male employees are managers. Suppose that an employee is chosen at random.

1. Find the probability that the employee is female.
2. Find the probability that the employee is a manager.
3. Find the conditional probability that the employee is a manager given that the employee is female.
4. Find the conditional probability that the employee is female given that the employee is a manager.
5. Are the events *female* and *manager* positively correlated, negatively correlated, or independent?

Answer

1. $\frac{120}{200}$
2. $\frac{50}{200}$
3. $\frac{30}{120}$
4. $\frac{30}{50}$
5. independent

Dice and Coins

Consider the experiment that consists of rolling 2 standard, fair dice and recording the sequence of scores $\mathbf{X} = (X_1, X_2)$. Let Y denote the sum of the scores. For each of the following pairs of events, find the probability of each event and the conditional probability of each event given the other. Determine whether the events are positively correlated, negatively correlated, or independent.

1. $\{X_1 = 3\}, \{Y = 5\}$
2. $\{X_1 = 3\}, \{Y = 7\}$
3. $\{X_1 = 2\}, \{Y = 5\}$
4. $\{X_1 = 3\}, \{X_1 = 2\}$

Answer

In each case below, the answers are for $\mathbb{P}(A)$, $\mathbb{P}(B)$, $\mathbb{P}(A | B)$, and $\mathbb{P}(B | A)$

1. $\frac{1}{6}, \frac{1}{9}, \frac{1}{4}, \frac{1}{6}$. Positively correlated.
2. $\frac{1}{6}, \frac{1}{6}, \frac{1}{6}, \frac{1}{6}$. Independent.
3. $\frac{1}{6}, \frac{1}{9}, \frac{1}{4}, \frac{1}{6}$. Positively correlated.
4. $\frac{1}{6}, \frac{1}{6}, 0, 0$. Negatively correlated.

Note that positive correlation is not a transitive relation. From the previous exercise, for example, note that $\{X_1 = 3\}$ and $\{Y = 5\}$ are positively correlated, $\{Y = 5\}$ and $\{X_1 = 2\}$ are positively correlated, but $\{X_1 = 3\}$ and $\{X_1 = 2\}$ are negatively correlated (in fact, disjoint).

In dice experiment, set $n = 2$. Run the experiment 1000 times. Compute the empirical conditional probabilities corresponding to the conditional probabilities in the last exercise.

Consider again the experiment that consists of rolling 2 standard, fair dice and recording the sequence of scores $\mathbf{X} = (X_1, X_2)$. Let Y denote the sum of the scores, U the minimum score, and V the maximum score.

1. Find $\mathbb{P}(U = u | V = 4)$ for the appropriate values of u .
2. Find $\mathbb{P}(Y = y | V = 4)$ for the appropriate values of y .
3. Find $\mathbb{P}(V = v | Y = 8)$ for appropriate values of v .
4. Find $\mathbb{P}(U = u | Y = 8)$ for the appropriate values of u .
5. Find $\mathbb{P}[(X_1, X_2) = (x_1, x_2) | Y = 8]$ for the appropriate values of (x_1, x_2) .

Answer

1. $\frac{2}{7}$ for $u \in \{1, 2, 3\}$, $\frac{1}{7}$ for $u = 4$
2. $\frac{2}{7}$ for $y \in \{5, 6, 7\}$, $\frac{1}{7}$ for $y = 8$
3. $\frac{1}{5}$ for $v = 4$, $\frac{2}{5}$ for $v \in \{5, 6\}$
4. $\frac{2}{5}$ for $u \in \{2, 3\}$, $\frac{1}{5}$ for $u = 4$
5. $\frac{1}{5}$ for $(x_1, x_2) \in \{(2, 6), (6, 2), (3, 5), (5, 3), (4, 4)\}$

In the die-coin experiment, a standard, fair die is rolled and then a fair coin is tossed the number of times showing on the die. Let N denote the die score and H the event that all coin tosses result in heads.

1. Find $\mathbb{P}(H)$.
2. Find $\mathbb{P}(N = n | H)$ for $n \in \{1, 2, 3, 4, 5, 6\}$
3. Compare the results in (b) with $\mathbb{P}(N = n)$ for $n \in \{1, 2, 3, 4, 5, 6\}$. In each case, note whether the events H and $\{N = n\}$ are positively correlated, negatively correlated, or independent.

Answer

1. $\frac{21}{128}$
2. $\frac{64}{63} \frac{1}{2^n}$ for $n \in \{1, 2, 3, 4, 5, 6\}$
3. positively correlated for $n \in \{1, 2\}$ and negatively correlated for $n \in \{3, 4, 5, 6\}$

Run the die-coin experiment 1000 times. Let H and N be as defined in the previous exercise.

1. Compute the empirical probability of H . Compare with the true probability in the previous exercise.
2. Compute the empirical probability of $\{N = n\}$ given H , for $n \in \{1, 2, 3, 4, 5, 6\}$. Compare with the true probabilities in the previous exercise.

Suppose that a bag contains 12 coins: 5 are fair, 4 are biased with probability of heads $\frac{1}{3}$; and 3 are two-headed. A coin is chosen at random from the bag and tossed.

1. Find the probability that the coin is heads.
2. Given that the coin is heads, find the conditional probability of each coin type.

Answer

1. $\frac{41}{72}$
2. $\frac{15}{41}$ that the coin is fair, $\frac{8}{41}$ that the coin is biased, $\frac{18}{41}$ that the coin is two-headed

Compare [die-coin experiment](#) and [bag of coins experiment](#). In the die-coin experiment, we toss a coin with a *fixed* probability of heads a *random* number of times. In the bag of coins experiment, we effectively toss a coin with a *random* probability of heads a *fixed* number of times. The random experiment of tossing a coin with a fixed probability of heads p a fixed number of times n is known as the *binomial experiment* with parameters n and p . This is a very basic and important experiment that is studied in more detail in the section on the binomial distribution in the chapter on Bernoulli Trials. Thus, the die-coin and bag of coins experiments can be thought of as modifications of the binomial experiment in which a parameter has been *randomized*. In general, interesting new random experiments can often be constructed by randomizing one or more parameters in another random experiment.

In the coin-die experiment, a fair coin is tossed. If the coin lands tails, a fair die is rolled. If the coin lands heads, an ace-six flat die is tossed (faces 1 and 6 have probability $\frac{1}{4}$ each, while faces 2, 3, 4, and 5 have probability $\frac{1}{8}$ each). Let H denote the event that the coin lands heads, and let Y denote the score when the chosen die is tossed.

1. Find $\mathbb{P}(Y = y)$ for $y \in \{1, 2, 3, 4, 5, 6\}$.
2. Find $\mathbb{P}(H | Y = y)$ for $y \in \{1, 2, 3, 4, 5, 6\}$.
3. Compare each probability in part (b) with $\mathbb{P}(H)$. In each case, note whether the events H and $\{Y = y\}$ are positively correlated, negatively correlated, or independent.

Answer

1. $\frac{5}{24}$ for $y \in \{1, 6\}$, $\frac{7}{48}$ for $y \in \{2, 3, 4, 5\}$
2. $\frac{3}{5}$ for $y \in \{1, 6\}$, $\frac{3}{7}$ for $y \in \{2, 3, 4, 5\}$
3. Positively correlated for $y \in \{1, 6\}$, negatively correlated for $y \in \{2, 3, 4, 5\}$

Run the coin-die experiment 1000 times. Let H and Y be as defined in the previous exercise.

1. Compute the empirical probability of $\{Y = y\}$, for each y , and compare with the true probability in the previous exercise
2. Compute the empirical probability of H given $\{Y = y\}$ for each y , and compare with the true probability in the previous exercise.

Cards

Consider the card experiment that consists of dealing 2 cards from a standard deck and recording the sequence of cards dealt. For $i \in \{1, 2\}$, let Q_i be the event that card i is a queen and H_i the event that card i is a heart. For each of the following pairs of events, compute the probability of each event, and the conditional probability of each event given the other. Determine whether the events are positively correlated, negatively correlated, or independent.

1. Q_1, H_1
2. Q_1, Q_2
3. Q_2, H_2
4. Q_1, H_2

Answer

The answers below are for $\mathbb{P}(A)$, $\mathbb{P}(B)$, $\mathbb{P}(A | B)$, and $\mathbb{P}(B | A)$ where A and B are the given events

1. $\frac{1}{13}, \frac{1}{4}, \frac{1}{13}, \frac{1}{4}$, independent.
2. $\frac{1}{13}, \frac{1}{13}, \frac{3}{51}, \frac{3}{51}$, negatively correlated.
3. $\frac{1}{13}, \frac{1}{4}, \frac{1}{13}, \frac{1}{4}$, independent.
4. $\frac{1}{13}, \frac{1}{4}, \frac{1}{13}, \frac{1}{4}$, independent.

In the card experiment, set $n = 2$. Run the experiment 500 times. Compute the conditional relative frequencies corresponding to the conditional probabilities in the last exercise.

Consider the card experiment that consists of dealing 3 cards from a standard deck and recording the sequence of cards dealt. Find the probability of the following events:

1. All three cards are all hearts.
2. The first two cards are hearts and the third is a spade.
3. The first and third cards are hearts and the second is a spade.

Proof

1. $\frac{11}{850}$
2. $\frac{13}{850}$
3. $\frac{13}{850}$

In the card experiment, set $n = 3$ and run the simulation 1000 times. Compute the empirical probability of each event in the previous exercise and compare with the true probability.

Bivariate Uniform Distributions

Recall that Buffon's coin experiment consists of tossing a coin with radius $r \leq \frac{1}{2}$ randomly on a floor covered with square tiles of side length 1. The coordinates (X, Y) of the center of the coin are recorded relative to axes through the center of the square, parallel to the sides. Since the needle is dropped randomly, the basic modeling assumption is that (X, Y) is uniformly distributed on the square $[-1/2, 1/2]^2$.

Figure 2.4.3: Buffon's coin experiment

In Buffon's coin experiment,

1. Find $\mathbb{P}(Y > 0 \mid X < Y)$
2. Find the conditional distribution of (X, Y) given that the coin does not touch the sides of the square.

Answer

1. $\frac{3}{4}$
2. Given $(X, Y) \in [r - \frac{1}{2}, \frac{1}{2} - r]^2$, (X, Y) is uniformly distributed on this set.

Run Buffon's coin experiment 500 times. Compute the empirical probability that $Y > 0$ given that $X < Y$ and compare with the probability in the last exercise.

In the conditional probability experiment, the random points are uniformly distributed on the rectangle S . Move and resize events A and B and note how the probabilities change. For each of the following configurations, run the experiment 1000 times and compare the relative frequencies with the true probabilities.

1. A and B in general position
2. A and B disjoint
3. $A \subseteq B$
4. $B \subseteq A$

Reliability

A plant has 3 assembly lines that produces memory chips. Line 1 produces 50% of the chips and has a defective rate of 4%; line 2 has produces 30% of the chips and has a defective rate of 5%; line 3 produces 20% of the chips and has a defective rate of 1%. A chip is chosen at random from the plant.

1. Find the probability that the chip is defective.
2. Given that the chip is defective, find the conditional probability for each line.

Answer

1. 0.037
2. 0.541 for line 1, 0.405 for line 2, 0.054 for line 3

Suppose that a bit (0 or 1) is sent through a noisy communications channel. Because of the noise, the bit sent may be received incorrectly as the complementary bit. Specifically, suppose that if 0 is sent, then the probability that 0 is received is 0.9 and the probability that 1 is received is 0.1. If 1 is sent, then the probability that 1 is received is 0.8 and the probability that 0 is received is 0.2. Finally, suppose that 1 is sent with probability 0.6 and 0 is sent with probability 0.4. Find the probability that

1. 1 was sent given that 1 was received
2. 0 was sent given that 0 was received

Answer

1. 12/13
2. 3/4

Suppose that T denotes the lifetime of a light bulb (in 1000 hour units), and that T has the following exponential distribution, defined for measurable $A \subseteq [0, \infty)$:

$$\mathbb{P}(T \in A) = \int_A e^{-t} dt \quad (2.4.23)$$

1. Find $\mathbb{P}(T > 3)$
2. Find $\mathbb{P}(T > 5 \mid T > 2)$

Answer

1. e^{-3}
2. e^{-3}

Suppose again that T denotes the lifetime of a light bulb (in 1000 hour units), but that T is uniformly distributed on the interval $[0, 10]$.

1. Find $\mathbb{P}(T > 3)$
2. Find $\mathbb{P}(T > 5 \mid T > 2)$

Answer

1. $\frac{7}{10}$
2. $\frac{5}{8}$

Genetics

Please refer to the discussion of genetics in the section on random experiments if you need to review some of the definitions in this section.

Recall first that the *ABO blood type* in humans is determined by three alleles: a , b , and o . Furthermore, a and b are co-dominant and o is recessive. Suppose that the probability distribution for the set of blood genotypes in a certain population is given in the following table:

Genotype	aa	ab	ao	bb	bo	oo
Probability	0.050	0.038	0.310	0.007	0.116	0.479

Suppose that a person is chosen at random from the population. Let A , B , AB , and O be the events that the person is type A , type B , type AB , and type O respectively. Let H be the event that the person is homozygous, and let D denote the event that the person has an o allele. Find each of the following:

1. $\mathbb{P}(A)$, $\mathbb{P}(B)$, $\mathbb{P}(AB)$, $\mathbb{P}(O)$, $\mathbb{P}(H)$, $\mathbb{P}(D)$

2. $P(A \cap H)$, $P(A | H)$, $P(H | A)$. Are the events A and H positively correlated, negatively correlated, or independent?
3. $P(B \cap H)$, $P(B | H)$, $P(H | B)$. Are the events B and H positively correlated, negatively correlated, or independent?
4. $P(A \cap D)$, $P(A | D)$, $P(D | A)$. Are the events A and D positively correlated, negatively correlated, or independent?
5. $P(B \cap D)$, $P(B | D)$, $P(D | B)$. Are the events B and D positively correlated, negatively correlated, or independent?
6. $P(H \cap D)$, $P(H | D)$, $P(D | H)$. Are the events H and D positively correlated, negatively correlated, or independent?

Answer

1. 0.360, 0.123, 0.038, 0.479, 0.536, 0.905
2. 0.050, 0.093, 0.139. A and H are negatively correlated.
3. 0.007, 0.013, 0.057. B and H are negatively correlated.
4. 0.310, 0.343, 0.861. A and D are negatively correlated.
5. 0.116, 0.128, 0.943. B and D are positively correlated.
6. 0.479, 0.529, 0.894. H and D are negatively correlated.

Suppose next that pod color in certain type of pea plant is determined by a gene with two alleles: g for green and y for yellow, and that g is dominant and y recessive.

Suppose that a green-pod plant and a yellow-pod plant are bred together. Suppose further that the green-pod plant has a $\frac{1}{4}$ chance of carrying the recessive yellow-pod allele.

1. Find the probability that a child plant will have green pods.
2. Given that a child plant has green pods, find the updated probability that the green-pod parent has the recessive allele.

Answer

1. $\frac{7}{8}$
2. $\frac{1}{7}$

Suppose that two green-pod plants are bred together. Suppose further that with probability $\frac{1}{3}$ neither plant has the recessive allele, with probability $\frac{1}{2}$ one plant has the recessive allele, and with probability $\frac{1}{6}$ both plants have the recessive allele.

1. Find the probability that a child plant has green pods.
2. Given that a child plant has green pods, find the updated probability that both parents have the recessive gene.

Answer

1. $\frac{23}{24}$
2. $\frac{3}{23}$

Next consider a sex-linked hereditary disorder in humans (such as colorblindness or hemophilia). Let h denote the healthy allele and d the defective allele for the gene linked to the disorder. Recall that h is dominant and d recessive for women.

Suppose that in a certain population, 50% are male and 50% are female. Moreover, suppose that 10% of males are color blind but only 1% of females are color blind.

1. Find the percentage of color blind persons in the population.
2. Find the percentage of color blind persons that are male.

Answer

1. 5.5%
2. 90.9%

Since color blindness is a sex-linked hereditary disorder, note that it's reasonable in the previous exercise that the probability that a female is color blind is the square of the probability that a male is color blind. If p is the probability of the defective allele on the X chromosome, then p is also the probability that a male will be color blind. But since the defective allele is recessive, a woman would need two copies of the defective allele to be color blind, and assuming independence, the probability of this event is p^2 .

A man and a woman do not have a certain sex-linked hereditary disorder, but the woman has a $\frac{1}{3}$ chance of being a carrier.

1. Find the probability that a son born to the couple will be normal.

2. Find the probability that a daughter born to the couple will be a carrier.
3. Given that a son born to the couple is normal, find the updated probability that the mother is a carrier.

Answer

1. $\frac{5}{6}$
2. $\frac{1}{6}$
3. $\frac{1}{5}$

Urn Models

Urn 1 contains 4 red and 6 green balls while urn 2 contains 7 red and 3 green balls. An urn is chosen at random and then a ball is chosen at random from the selected urn.

1. Find the probability that the ball is green.
2. Given that the ball is green, find the conditional probability that urn 1 was selected.

Answer

1. $\frac{9}{20}$
2. $\frac{2}{3}$

Urn 1 contains 4 red and 6 green balls while urn 2 contains 6 red and 3 green balls. A ball is selected at random from urn 1 and transferred to urn 2. Then a ball is selected at random from urn 2.

1. Find the probability that the ball from urn 2 is green.
2. Given that the ball from urn 2 is green, find the conditional probability that the ball from urn 1 was green.

Answer

1. $\frac{9}{25}$
2. $\frac{2}{3}$

An urn initially contains 6 red and 4 green balls. A ball is chosen at random from the urn and its color is recorded. It is then replaced in the urn and 2 new balls of the same color are added to the urn. The process is repeated. Find the probability of each of the following events:

1. Balls 1 and 2 are red and ball 3 is green.
2. Balls 1 and 3 are red and ball 2 is green.
3. Ball 1 is green and balls 2 and 3 are red.
4. Ball 2 is red.
5. Ball 1 is red given that ball 2 is red.

Answer

1. $\frac{4}{35}$
2. $\frac{4}{35}$
3. $\frac{4}{35}$
4. $\frac{3}{5}$
5. $\frac{2}{3}$

Think about the results in the previous exercise. Note in particular that the answers to parts (a), (b), and (c) are the same, and that the probability that the second ball is red in part (d) is the same as the probability that the first ball is red. More generally, the probabilities of events do not depend on the order of the draws. For example, the probability of an event involving the first, second, and third draws is the same as the probability of the corresponding event involving the seventh, tenth and fifth draws. Technically, the sequence of events (R_1, R_2, \dots) is exchangeable. The random process described in this exercise is a special case of *Pólya's urn scheme*, named after George Pólya. We will study Pólya's urn in more detail in the chapter on Finite Sampling Models

An urn initially contains 6 red and 4 green balls. A ball is chosen at random from the urn and its color is recorded. It is then replaced in the urn and two new balls of the *other* color are added to the urn. The process is repeated. Find the probability of

each of the following events:

1. Balls 1 and 2 are red and ball 3 is green.
2. Balls 1 and 3 are red and ball 2 is green.
3. Ball 1 is green and balls 2 and 3 are red.
4. Ball 2 is red.
5. Ball 1 is red given that ball 2 is red.

Answer

1. $\frac{6}{35}$
2. $\frac{6}{35}$
3. $\frac{16}{105}$
4. $\frac{17}{30}$
5. $\frac{9}{17}$

Think about the results in the previous exercise, and compare with [Pólya's urn](#). Note that the answers to parts (a), (b), and (c) are not all the same, and that the probability that the second ball is red in part (d) is not the same as the probability that the first ball is red. In short, the sequence of events (R_1, R_2, \dots) is *not* exchangeable.

Diagnostic Testing

Suppose that we have a random experiment with an event A of interest. When we run the experiment, of course, event A will either occur or not occur. However, suppose that we are not able to observe the occurrence or non-occurrence of A directly. Instead we have a *diagnostic test* designed to indicate the occurrence of event A ; thus the test that can be either *positive* for A or *negative* for A . The test also has an element of randomness, and in particular can be in error. Here are some typical examples of the type of situation we have in mind:

- The event is that a person has a certain disease and the test is a blood test for the disease.
- The event is that a woman is pregnant and the test is a home pregnancy test.
- The event is that a person is lying and the test is a lie-detector test.
- The event is that a device is defective and the test consists of a sensor reading.
- The event is that a missile is in a certain region of airspace and the test consists of radar signals.
- The event is that a person has committed a crime, and the test is a jury trial with evidence presented for and against the event.

Let T be the event that the test is positive for the occurrence of A . The conditional probability $\mathbb{P}(T | A)$ is called the *sensitivity* of the test. The complementary probability

$$\mathbb{P}(T^c | A) = 1 - \mathbb{P}(T | A) \quad (2.4.24)$$

is the *false negative* probability. The conditional probability $\mathbb{P}(T^c | A^c)$ is called the *specificity* of the test. The complementary probability

$$\mathbb{P}(T | A^c) = 1 - \mathbb{P}(T^c | A^c) \quad (2.4.25)$$

is the *false positive* probability. In many cases, the sensitivity and specificity of the test are known, as a result of the development of the test. However, the *user* of the test is interested in the opposite conditional probabilities, namely $\mathbb{P}(A | T)$, the probability of the event of interest, given a positive test, and $\mathbb{P}(A^c | T^c)$, the probability of the complementary event, given a negative test. Of course, if we know $\mathbb{P}(A | T)$ then we also have $\mathbb{P}(A^c | T) = 1 - \mathbb{P}(A | T)$, the probability of the complementary event given a positive test. Similarly, if we know $\mathbb{P}(A^c | T^c)$ then we also have $\mathbb{P}(A | T^c)$, the probability of the event given a negative test. Computing the probabilities of interest is simply a special case of Bayes' theorem.

The probability that the event occurs, given a positive test is

$$\mathbb{P}(A | T) = \frac{\mathbb{P}(A)\mathbb{P}(T | A)}{\mathbb{P}(A)\mathbb{P}(T | A) + \mathbb{P}(A^c)\mathbb{P}(T | A^c)} \quad (2.4.26)$$

The probability that the event does not occur, given a negative test is

$$\mathbb{P}(A^c | T^c) = \frac{\mathbb{P}(A^c)\mathbb{P}(T^c | A^c)}{\mathbb{P}(A)\mathbb{P}(T^c | A) + \mathbb{P}(A^c)\mathbb{P}(T^c | A^c)} \quad (2.4.27)$$

There is often a trade-off between sensitivity and specificity. An attempt to make a test more sensitive may result in the test being less specific, and an attempt to make a test more specific may result in the test being less sensitive. As an extreme example, consider the worthless test that always returns positive, no matter what the evidence. Then $T = S$ so the test has sensitivity 1, but specificity 0. At the opposite extreme is the worthless test that always returns negative, no matter what the evidence. Then $T = \emptyset$ so the test has specificity 1 but sensitivity 0. In between these extremes are helpful tests that are actually based on evidence of some sort.

Suppose that the sensitivity $a = \mathbb{P}(T | A) \in (0, 1)$ and the specificity $b = \mathbb{P}(T^c | A^c) \in (0, 1)$ are fixed. Let $p = \mathbb{P}(A)$ denote the prior probability of the event A and $P = \mathbb{P}(A | T)$ the posterior probability of A given a positive test.

P as a function of p is given by

$$P = \frac{ap}{(a+b-1)p + (1-b)}, \quad p \in [0, 1] \quad (2.4.28)$$

1. P increases continuously from 0 to 1 as p increases from 0 to 1.
2. P is concave downward if $a + b > 1$. In this case A and T are positively correlated.
3. P is concave upward if $a + b < 1$. In this case A and T are negatively correlated.
4. $P = p$ if $a + b = 1$. In this case, A and T are uncorrelated (independent).

Proof

The formula for P in terms of p follows from (42) and algebra. For part (a), note that

$$\frac{dP}{dp} = \frac{a(1-b)}{[(a+b-1)p + (1-b)]^2} > 0 \quad (2.4.29)$$

For parts (b)-(d), note that

$$\frac{d^2P}{dp^2} = \frac{-2a(1-b)(a+b-1)}{[(1+b-1)p + (1-b)]^3} \quad (2.4.30)$$

If $a + b > 1$, $d^2P/dp^2 < 0$ so P is concave downward on $[0, 1]$ and hence $P > p$ for $0 < p < 1$. If $a + b < 1$, $d^2P/dp^2 > 0$ so P is concave upward on $[0, 1]$ and hence $P < p$ for $0 < p < 1$. Trivially if $a + b = 1$, $P = p$ for $0 \leq p \leq 1$.

Of course, part (b) is the typical case, where the test is useful. In fact, we would hope that the sensitivity and specificity are close to 1. In case (c), the test is worse than useless since it gives the wrong information about A . But this case could be turned into a useful test by simply reversing the roles of *positive* and *negative*. In case (d), the test is worthless and gives no information about A . It's interesting that the broad classification above depends only on the *sum* of the sensitivity and specificity.

Figure 2.4.4: $P = \mathbb{P}(A | T)$ as a function of $p = \mathbb{P}(A)$ in the three cases

Suppose that a diagnostic test has sensitivity 0.99 and specificity 0.95. Find $\mathbb{P}(A | T)$ for each of the following values of $\mathbb{P}(A)$:

1. 0.001
2. 0.01
3. 0.2
4. 0.5
5. 0.7
6. 0.9

Answer

1. 0.0194
2. 0.1667
3. 0.8319
4. 0.9519
5. 0.9788
6. 0.9944

With sensitivity 0.99 and specificity 0.95, the test in the last exercise superficially looks good. However the small value of $\mathbb{P}(A | T)$ for small values of $\mathbb{P}(A)$ is striking (but inevitable given the [properties above](#)). The moral, of course, is that $\mathbb{P}(A | T)$ depends critically on $\mathbb{P}(A)$ not just on the sensitivity and specificity of the test. Moreover, the correct comparison is $\mathbb{P}(A | T)$ with $\mathbb{P}(A)$, as in the exercise, not $\mathbb{P}(A | T)$ with $\mathbb{P}(T | A)$ —Beware of the fallacy of the transposed conditional! In terms of the correct comparison, the test does indeed work well; $\mathbb{P}(A | T)$ is significantly larger than $\mathbb{P}(A)$ in all cases.

A woman initially believes that there is an even chance that she is or is not pregnant. She takes a home pregnancy test with sensitivity 0.95 and specificity 0.90 (which are reasonable values for a home pregnancy test). Find the updated probability that the woman is pregnant in each of the following cases.

1. The test is positive.
2. The test is negative.

Answer

1. 0.905
2. 0.053

Suppose that 70% of defendants brought to trial for a certain type of crime are guilty. Moreover, historical data show that juries convict guilty persons 80% of the time and convict innocent persons 10% of the time. Suppose that a person is tried for a crime of this type. Find the updated probability that the person is guilty in each of the following cases:

1. The person is convicted.
2. The person is acquitted.

Answer

1. 0.949
2. 0.341

The “Check Engine” light on your car has turned on. Without the information from the light, you believe that there is a 10% chance that your car has a serious engine problem. You learn that if the car has such a problem, the light will come on with probability 0.99, but if the car does not have a serious problem, the light will still come on, under circumstances similar to yours, with probability 0.3. Find the updated probability that you have an engine problem.

Answer

0.268

The standard test for HIV is the *ELISA* (*Enzyme-Linked Immunosorbent Assay*) test. It has sensitivity and specificity of 0.999. Suppose that a person is selected at random from a population in which 1% are infected with HIV, and given the ELISA test. Find the probability that the person has HIV in each of the following cases:

1. The test is positive.
2. The test is negative.

Answer

1. 0.9098
2. 0.00001

The ELISA test for HIV is a very good one. Let's look another test, this one for prostate cancer, that's rather bad.

The PSA test for prostate cancer is based on a blood marker known as the *Prostate Specific Antigen*. An elevated level of PSA is evidence for prostate cancer. To have a diagnostic test, in the sense that we are discussing here, we must decide on a definite level of PSA, above which we declare the test to be positive. A positive test would typically lead to other more invasive tests (such as biopsy) which, of course, carry risks and cost. The PSA test with cutoff 2.6 ng/ml has sensitivity 0.40 and specificity 0.81. The overall incidence of prostate cancer among males is 156 per 100000. Suppose that a man, with no particular risk factors, has the PSA test. Find the probability that the man has prostate cancer in each of the following cases:

1. The test is positive.
2. The test is negative.

Answer

1. 0.00328
2. 0.00116

Diagnostic testing is closely related to a general statistical procedure known as *hypothesis testing*. A separate chapter on hypothesis testing explores this procedure in detail.

Data Analysis Exercises

For the M&M data set, find the empirical probability that a bag has at least 10 reds, given that the weight of the bag is at least 48 grams.

Answer

$$\frac{10}{23}.$$

Consider the Cicada data.

1. Find the empirical probability that a cicada weighs at least 0.25 grams given that the cicada is male.
2. Find the empirical probability that a cicada weighs at least 0.25 grams given that the cicada is the tredecula species.

Answer

1. $\frac{2}{45}$
2. $\frac{7}{44}$

This page titled [2.4: Conditional Probability](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

2.5: Independence

In this section, we will discuss independence, one of the fundamental concepts in probability theory. Independence is frequently invoked as a modeling assumption, and moreover, (classical) probability itself is based on the idea of independent replications of the experiment. As usual, if you are a new student of probability, you may want to skip the technical details.

Basic Theory

As usual, our starting point is a random experiment modeled by a probability space $(S, \mathcal{S}, \mathbb{P})$ so that S is the set of outcomes, \mathcal{S} the collection of events, and \mathbb{P} the probability measure on the sample space (S, \mathcal{S}) . We will define independence for two events, then for collections of events, and then for collections of random variables. In each case, the basic idea is the same.

Independence of Two Events

Two events A and B are independent if

$$\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B) \quad (2.5.1)$$

If both of the events have positive probability, then independence is equivalent to the statement that the conditional probability of one event given the other is the same as the unconditional probability of the event:

$$\mathbb{P}(A | B) = \mathbb{P}(A) \iff \mathbb{P}(B | A) = \mathbb{P}(B) \iff \mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B) \quad (2.5.2)$$

This is how you should think of independence: knowledge that one event has occurred does not change the probability assigned to the other event. Independence of two events was discussed in the last section in the context of correlation. In particular, for two events, *independent* and *uncorrelated* mean the same thing.

The terms *independent* and *disjoint* sound vaguely similar but they are actually very different. First, note that disjointness is purely a set-theory concept while independence is a probability (measure-theoretic) concept. Indeed, two events can be independent relative to one probability measure and dependent relative to another. But most importantly, two disjoint events can *never* be independent, except in the trivial case that one of the events is null.

Suppose that A and B are disjoint events, each with positive probability. Then A and B are dependent, and in fact are negatively correlated.

Proof

Note that $\mathbb{P}(A \cap B) = \mathbb{P}(\emptyset) = 0$ but $\mathbb{P}(A)\mathbb{P}(B) > 0$.

If A and B are independent events then intuitively it seems clear that any event that can be constructed from A should be independent of any event that can be constructed from B . This is the case, as the next result shows. Moreover, this basic idea is essential for the generalization of independence that we will consider shortly.

If A and B are independent events, then each of the following pairs of events is independent:

1. A^c, B
2. B, A^c
3. A^c, B^c

Proof

Suppose that A and B are independent. Then by the difference rule and the complement rule,

$$\mathbb{P}(A^c \cap B) = \mathbb{P}(B) - \mathbb{P}(A \cap B) = \mathbb{P}(B) - \mathbb{P}(A)\mathbb{P}(B) = \mathbb{P}(B)[1 - \mathbb{P}(A)] = \mathbb{P}(B)\mathbb{P}(A^c) \quad (2.5.3)$$

Hence A^c and B are equivalent. Parts (b) and (c) follow from (a).

An event that is “essentially deterministic”, that is, has probability 0 or 1, is independent of any other event, even itself.

Suppose that A and B are events.

1. If $\mathbb{P}(A) = 0$ or $\mathbb{P}(A) = 1$, then A and B are independent.
2. A is independent of itself if and only if $\mathbb{P}(A) = 0$ or $\mathbb{P}(A) = 1$.

Proof

1. Recall that if $\mathbb{P}(A) = 0$ then $\mathbb{P}(A \cap B) = 0$, and if $\mathbb{P}(A) = 1$ then $\mathbb{P}(A \cap B) = \mathbb{P}(B)$. In either case we have $\mathbb{P}(A \cap B) = \mathbb{P}(A)\mathbb{P}(B)$.
2. The independence of A with itself gives $\mathbb{P}(A) = [\mathbb{P}(A)]^2$ and hence either $\mathbb{P}(A) = 0$ or $\mathbb{P}(A) = 1$.

General Independence of Events

To extend the definition of independence to more than two events, we might think that we could just require *pairwise independence*, the independence of each pair of events. However, this is not sufficient for the *strong* type of independence that we have in mind. For example, suppose that we have three events A , B , and C . *Mutual* independence of these events should not only mean that each pair is independent, but also that an event that can be constructed from A and B (for example $A \cup B^c$) should be independent of C . Pairwise independence does not achieve this; an [exercise](#) below gives three events that are pairwise independent, but the intersection of two of the events is related to the third event in the strongest possible sense.

Another possible generalization would be to simply require the probability of the intersection of the events to be the product of the probabilities of the events. However, this condition does not even guarantee pairwise independence. An [exercise](#) below gives an example. However, the definition of independence for two events does generalize in a natural way to an arbitrary collection of events.

Suppose that A_i is an event for each i in an index set I . Then the collection $\mathcal{A} = \{A_i : i \in I\}$ is *independent* if for every finite $J \subseteq I$,

$$\mathbb{P}\left(\bigcap_{j \in J} A_j\right) = \prod_{j \in J} \mathbb{P}(A_j) \quad (2.5.4)$$

Independence of a collection of events is much stronger than mere pairwise independence of the events in the collection. The basic *inheritance property* in the following result follows immediately from the definition.

Suppose that \mathcal{A} is a collection of events.

1. If \mathcal{A} is independent, then \mathcal{B} is independent for every $\mathcal{B} \subseteq \mathcal{A}$.
2. If \mathcal{B} is independent for every finite $\mathcal{B} \subseteq \mathcal{A}$ then \mathcal{A} is independent.

For a finite collection of events, the number of conditions required for mutual independence grows exponentially with the number of events.

There are $2^n - n - 1$ non-trivial conditions in the definition of the independence of n events.

1. Explicitly give the 4 conditions that must be satisfied for events A , B , and C to be independent.
2. Explicitly give the 11 conditions that must be satisfied for events A , B , C , and D to be independent.

Answer

There are 2^n subcollections of the n events. One is empty and n involve a single event. The remaining $2^n - n - 1$ subcollections involve two or more events and correspond to non-trivial conditions.

1. A , B , C are independent if and only if

$$\begin{aligned} \mathbb{P}(A \cap B) &= \mathbb{P}(A)\mathbb{P}(B) \\ \mathbb{P}(A \cap C) &= \mathbb{P}(A)\mathbb{P}(C) \\ \mathbb{P}(B \cap C) &= \mathbb{P}(B)\mathbb{P}(C) \\ \mathbb{P}(A \cap B \cap C) &= \mathbb{P}(A)\mathbb{P}(B)\mathbb{P}(C) \end{aligned}$$

2. A , B , C , D are independent if and only if

$$\begin{aligned}
 \mathbb{P}(A \cap B) &= \mathbb{P}(A)\mathbb{P}(B) \\
 \mathbb{P}(A \cap C) &= \mathbb{P}(A)\mathbb{P}(C) \\
 \mathbb{P}(A \cap D) &= \mathbb{P}(A)\mathbb{P}(D) \\
 \mathbb{P}(B \cap C) &= \mathbb{P}(B)\mathbb{P}(C) \\
 \mathbb{P}(B \cap D) &= \mathbb{P}(B)\mathbb{P}(D) \\
 \mathbb{P}(C \cap D) &= \mathbb{P}(C)\mathbb{P}(D) \\
 \mathbb{P}(A \cap B \cap C) &= \mathbb{P}(A)\mathbb{P}(B)\mathbb{P}(C) \\
 \mathbb{P}(A \cap B \cap D) &= \mathbb{P}(A)\mathbb{P}(B)\mathbb{P}(D) \\
 \mathbb{P}(A \cap C \cap D) &= \mathbb{P}(A)\mathbb{P}(C)\mathbb{P}(D) \\
 \mathbb{P}(B \cap C \cap D) &= \mathbb{P}(B)\mathbb{P}(C)\mathbb{P}(D) \\
 \mathbb{P}(A \cap B \cap C \cap D) &= \mathbb{P}(A)\mathbb{P}(B)\mathbb{P}(C)\mathbb{P}(D)
 \end{aligned}$$

If the events A_1, A_2, \dots, A_n are independent, then it follows immediately from the definition that

$$\mathbb{P}\left(\bigcap_{i=1}^n A_i\right) = \prod_{i=1}^n \mathbb{P}(A_i) \quad (2.5.5)$$

This is known as the *multiplication rule* for independent events. Compare this with the general multiplication rule for conditional probability.

The collection of *essentially deterministic* events $\mathcal{D} = \{A \in \mathcal{S} : \mathbb{P}(A) = 0 \text{ or } \mathbb{P}(A) = 1\}$ is independent.

Proof

Suppose that $\{A_1, A_2, \dots, A_n\} \subseteq \mathcal{D}$. If $\mathbb{P}(A_i) = 0$ for some $i \in \{1, 2, \dots, n\}$ then $\mathbb{P}(A_1 \cap A_2 \cap \dots \cap A_n) = 0$. If $\mathbb{P}(A_i) = 1$ for every $i \in \{1, 2, \dots, n\}$ then $\mathbb{P}(A_1 \cap A_2 \cap \dots \cap A_n) = 1$. In either case, $\mathbb{P}(A_1 \cap A_2 \cap \dots \cap A_n) = \mathbb{P}(A_1)\mathbb{P}(A_2) \cdots \mathbb{P}(A_n)$.

The next result generalizes the [theorem above](#) on the complements of two independent events.

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ and $\mathcal{B} = \{B_i : i \in I\}$ are two collections of events with the property that for each $i \in I$, either $B_i = A_i$ or $B_i = A_i^c$. Then \mathcal{A} is independent if and only if \mathcal{B} is an independent.

Proof

The proof is actually very similar to the proof for [two events](#), except for more complicated notation. First, by the symmetry of the relation between \mathcal{A} and \mathcal{B} , it suffices to show \mathcal{A} independent implies \mathcal{B} independent. Next, by the [inheritance property](#), it suffices to consider the case where the index set I is finite.

1. Fix $k \in I$ and define $B_k = A_k^c$ and $B_i = A_i$ for $i \in I \setminus \{k\}$. Suppose now that $J \subseteq I$. If $k \notin J$ then trivially,

$$\mathbb{P}\left(\bigcap_{j \in J} B_j\right) = \prod_{j \in J} \mathbb{P}(B_j).$$

$$\begin{aligned}
 \mathbb{P}\left(\bigcap_{j \in J} B_j\right) &= \mathbb{P}\left(\bigcap_{j \in J \setminus \{k\}} A_j\right) - \mathbb{P}\left(\bigcap_{j \in J} A_j\right) \\
 &= \prod_{j \in J \setminus \{k\}} \mathbb{P}(A_j) - \prod_{j \in J} \mathbb{P}(A_j) = \left[\prod_{j \in J \setminus \{k\}} \mathbb{P}(A_j) \right] [1 - \mathbb{P}(A_k)] = \prod_{j \in J} \mathbb{P}(B_j)
 \end{aligned}$$

Hence $\{B_i : i \in I\}$ is a collection of independent events.

2. Suppose now that $\mathcal{B} = \{B_i : i \in I\}$ is a general collection of events where $B_i = A_i$ or $B_i = A_i^c$ for each $i \in I$. Then \mathcal{B} can be obtained from \mathcal{A} by a finite sequence of complement changes of the type in (a), each of which preserves independence.

The last theorem in turn leads to the type of strong independence that we want. The following exercise gives examples.

If A, B, C , and D are independent events, then

1. $A \cup B, C^c, D$ are independent.
2. $A \cup B^c, C^c \cup D^c$ are independent.

Proof

We will give proofs that use the [complement theorem](#), but to do so, some additional notation is helpful. If E is an event, let $E^1 = E$ and $E^0 = E^c$.

1. Note that $A \cup B = \bigcup_{(i,j) \in I} A^i \cap B^j$ where $I = \{(1, 0), (0, 1), (1, 1)\}$ and note that the events in the union are disjoint. By the distributive property, $(A \cup B) \cap C^c = \bigcup_{(i,j) \in I} A^i \cap B^j \cap C^0$ and again the events in the union are disjoint. By additivity and [complement theorem](#),

$$\mathbb{P}[(A \cup B) \cap C^c] = \sum_{(i,j) \in I} \mathbb{P}(A^i) \mathbb{P}(B^j) \mathbb{P}(C^0) = \left(\sum_{(i,j) \in I} \mathbb{P}(A^i) \mathbb{P}(B^j) \right) \mathbb{P}(C^0) = \mathbb{P}(A \cup B) \mathbb{P}(C^c) \quad (2.5.6)$$

By exactly the same type of argument, $\mathbb{P}[(A \cup B) \cap D] = \mathbb{P}(A \cup B) \mathbb{P}(D)$ and $\mathbb{P}[(A \cup B) \cap C^c \cap D] = \mathbb{P}(A \cup B) \mathbb{P}(C^c) \mathbb{P}(D)$. Directly from the result above on [complements](#), $\mathbb{P}(C^c \cap D) = \mathbb{P}(C^c) \mathbb{P}(D)$.

2. Note that $A \cup B^c = \bigcup_{(i,j) \in I} A^i \cap B^j$ where $I = \{(0, 0), (1, 0), (1, 1)\}$ and note that the events in the union are disjoint. Similarly $C^c \cup D^c = \bigcup_{(k,l) \in J} C^k \cap D^l$ where $J = \{(0, 0), (1, 0), (0, 1)\}$ and again the events in the union are disjoint. By the distributive rule for set operations,

$$(A \cup B^c) \cap (C^c \cup D^c) = \bigcup_{(i,j,k,l) \in I \times J} A^i \cap B^j \cap C^k \cap D^l \quad (2.5.7)$$

and once again, the events in the union are disjoint. By additivity and the [complement theorem](#),

$$\mathbb{P}[(A \cup B^c) \cap (C^c \cup D^c)] = \sum_{(i,j,k,l) \in I \times J} \mathbb{P}(A^i) \mathbb{P}(B^j) \mathbb{P}(C^k) \mathbb{P}(D^l) \quad (2.5.8)$$

But also by additivity, the [complement theorem](#), and the distributive property of arithmetic,

$$\mathbb{P}(A \cup B^c) \mathbb{P}(C^c \cup D^c) = \left(\sum_{(i,j) \in I} \mathbb{P}(A^i) \mathbb{P}(B^j) \right) \left(\sum_{(k,l) \in J} \mathbb{P}(C^k) \mathbb{P}(D^l) \right) = \sum_{(i,j,k,l) \in I \times J} \mathbb{P}(A^i) \mathbb{P}(B^j) \mathbb{P}(C^k) \mathbb{P}(D^l) \quad (2.5.9)$$

The complete generalization of these results is a bit complicated, but roughly means that if we start with a collection of independent events, and form new events from disjoint subcollections (using the set operations of union, intersection, and complement), then the new events are independent. For a precise statement, see the section on measure spaces. The importance of the [complement theorem](#) lies in the fact that any event that can be defined in terms of a finite collection of events $\{A_i : i \in I\}$ can be written as a disjoint union of events of the form $\bigcap_{i \in I} B_i$ where $B_i = A_i$ or $B_i = A_i^c$ for each $i \in I$.

Another consequence of the general [complement theorem](#) is a formula for the probability of the union of a collection of independent events that is much nicer than the inclusion-exclusion formula.

If A_1, A_2, \dots, A_n are independent events, then

$$\mathbb{P}\left(\bigcup_{i=1}^n A_i\right) = 1 - \prod_{i=1}^n [1 - \mathbb{P}(A_i)] \quad (2.5.10)$$

Proof

From DeMorgan's law and the independence of $A_1^c, A_2^c, \dots, A_n^c$ we have

$$\mathbb{P}\left(\bigcup_{i=1}^n A_i\right) = 1 - \mathbb{P}\left(\bigcap_{i=1}^n A_i^c\right) = 1 - \prod_{i=1}^n \mathbb{P}(A_i^c) = 1 - \prod_{i=1}^n [1 - \mathbb{P}(A_i)] \quad (2.5.11)$$

Independence of Random Variables

Suppose now that X_i is a random variable for the experiment with values in a set T_i for each i in a nonempty index set I . Mathematically, X_i is a function from S into T_i , and recall that $\{X_i \in B\}$ denotes the event $\{s \in S : X_i(s) \in B\}$ for $B \subseteq T_i$. Intuitively, X_i is a variable of interest in the experiment, and every meaningful statement about X_i defines an event. Intuitively, the random variables are independent if information about some of the variables tells us nothing about the other variables. Mathematically, independence of a collection of random variables can be reduced to the independence of collections of events.

The collection of random variables $\mathcal{X} = \{X_i : i \in I\}$ is *independent* if the collection of events $\{\{X_i \in B_i\} : i \in I\}$ is independent for every choice of $B_i \subseteq T_i$ for $i \in I$. Equivalently then, \mathcal{X} is independent if for every finite $J \subseteq I$, and for every choice of $B_j \subseteq T_j$

for $j \in J$ we have

$$\mathbb{P}\left(\bigcap_{j \in J} \{X_j \in B_j\}\right) = \prod_{j \in J} \mathbb{P}(X_j \in B_j) \quad (2.5.12)$$

Details

Recall that T_i will have a σ -algebra \mathcal{T}_i of admissible subsets so that (T_i, \mathcal{T}_i) is a measurable space just like the sample space (S, \mathcal{S}) for each $i \in I$. Also X_i is measurable as a function from S into T_i for each $i \in I$. These technical assumptions ensure that the definition makes sense.

Suppose that \mathcal{X} is a collection of random variables.

1. If \mathcal{X} is independent, then \mathcal{Y} is independent for every $\mathcal{Y} \subseteq \mathcal{X}$
2. If \mathcal{Y} is independent for every finite $\mathcal{Y} \subseteq \mathcal{X}$ then \mathcal{X} is independent.

It would seem almost obvious that if a collection of random variables is independent, and we transform each variable in deterministic way, then the new collection of random variables should still be independent.

Suppose now that g_i is a function from T_i into a set U_i for each $i \in I$. If $\{X_i : i \in I\}$ is independent, then $\{g_i(X_i) : i \in I\}$ is also independent.

Proof

Except for the abstract setting, the proof of independence is easy. Suppose that $C_i \subseteq U_i$ for each $i \in I$. Then $\{g_i(X_i) \in C_i\} = \{X_i \in g_i^{-1}(C_i)\}$ for $i \in I$. By the independence of $\{X_i : i \in I\}$, the collection of events $\{\{X_i \in g_i^{-1}(C_i)\} : i \in I\}$ is independent.

Technically, the set U_i will have a σ -algebra \mathcal{U}_i of admissible subsets so that (U_i, \mathcal{U}_i) is a measurable space just like (T_i, \mathcal{T}_i) and just like the sample space (S, \mathcal{S}) . The function g_i is required to be measurable as a function from T_i into U_i just as X_i is measurable as a function from S into T_i . In the proof above, $C_i \in \mathcal{U}_i$ so that $g_i^{-1}(C_i) \in \mathcal{T}_i$ and hence $\{X_i \in g_i^{-1}(C_i)\} \in \mathcal{S}$.

As with events, the (mutual) independence of random variables is a very strong property. If a collection of random variables is independent, then any subcollection is also independent. New random variables formed from disjoint subcollections are independent. For a simple example, suppose that X , Y , and Z are independent real-valued random variables. Then

1. $\sin(X)$, $\cos(Y)$, and e^Z are independent.
2. (X, Y) and Z are independent.
3. $X^2 + Y^2$ and $\arctan(Z)$ are independent.
4. X and Z are independent.
5. Y and Z are independent.

In particular, note that statement 2 in the list above is much stronger than the conjunction of statements 4 and 5. Contrapositively, if X and Z are dependent, then (X, Y) and Z are also dependent. Independence of random variables subsumes independence of events.

A collection of events \mathcal{A} is independent if and only if the corresponding collection of indicator variables $\{\mathbf{1}_{A_i} : A_i \in \mathcal{A}\}$ is independent.

Proof

Let $\mathcal{A} = \{A_i : i \in I\}$ where I is a nonempty index set. For $i \in I$, the only non-trivial events that can be defined in terms of $\mathbf{1}_{A_i}$ are $\{\mathbf{1}_{A_i} = 1\} = A_i$ and $\{\mathbf{1}_{A_i} = 0\} = A_i^c$. So $\{\mathbf{1}_{A_i} : i \in I\}$ is independent if and only if every collection of the form $\{B_i : i \in I\}$ is independent, where for each $i \in I$, either $B_i = A_i$ or $B_i = A_i^c$. But by the [complement theorem](#), this is equivalent to the independence of $\{A_i : i \in I\}$.

Many of the concepts that we have been using informally can now be made precise. A compound experiment that consists of “independent stages” is essentially just an experiment whose outcome is a sequence of independent random variables $\mathbf{X} = (X_1, X_2, \dots)$ where X_i is the outcome of the i th stage.

In particular, suppose that we have a basic experiment with outcome variable X . By definition, the outcome of the experiment that consists of “independent replications” of the basic experiment is a sequence of independent random variables $\mathbf{X} = (X_1, X_2, \dots)$ each with the same probability distribution as X . This is fundamental to the very concept of probability, as expressed in the law of large numbers. From a statistical point of view, suppose that we have a population of objects and a vector of measurements \mathbf{X} of interest for the objects in the

sample. The sequence \mathbf{X} above corresponds to *sampling from the distribution of X* ; that is, X_i is the vector of measurements for the i th object drawn from the sample. When we sample from a finite population, sampling *with replacement* generates independent random variables while sampling *without replacement* generates dependent random variables.

Conditional Independence and Conditional Probability

As noted at the beginning of our discussion, independence of events or random variables depends on the underlying probability measure. Thus, suppose that B is an event with positive probability. A collection of events or a collection of random variables is *conditionally independent given B* if the collection is independent relative to the conditional probability measure $A \mapsto \mathbb{P}(A | B)$. For example, a collection of events $\{A_i : i \in I\}$ is conditionally independent given B if for every finite $J \subseteq I$,

$$\mathbb{P}\left(\bigcap_{j \in J} A_j \mid B\right) = \prod_{j \in J} \mathbb{P}(A_j | B) \quad (2.5.13)$$

Note that the definitions and theorems of this section would still be true, but with all probabilities conditioned on B .

Conversely, conditional probability has a nice interpretation in terms of independent replications of the experiment. Thus, suppose that we start with a basic experiment with S as the set of outcomes. We let X denote the outcome random variable, so that mathematically X is simply the identity function on S . In particular, if A is an event then trivially, $\mathbb{P}(X \in A) = \mathbb{P}(A)$. Suppose now that we replicate the experiment independently. This results in a new, compound experiment with a sequence of independent random variables (X_1, X_2, \dots) , each with the same distribution as X . That is, X_i is the outcome of the i th repetition of the experiment.

Suppose now that A and B are events in the basic experiment with $\mathbb{P}(B) > 0$. In the compound experiment, the event that “when B occurs for the first time, A also occurs” has probability

$$\frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)} = \mathbb{P}(A | B) \quad (2.5.14)$$

Proof

In the compound experiment, if we record (X_1, X_2, \dots) then the new set of outcomes is $S^\infty = S \times S \times \dots$. The event that “when B occurs for the first time, A also occurs” is

$$\bigcup_{n=1}^{\infty} \{X_1 \notin B, X_2 \notin B, \dots, X_{n-1} \notin B, X_n \in A \cap B\} \quad (2.5.15)$$

The events in the union are disjoint. Also, since (X_1, X_2, \dots) is a sequence of independent variables, each with the distribution of X we have

$$\mathbb{P}(X_1 \notin B, X_2 \notin B, \dots, X_{n-1} \notin B, X_n \in A \cap B) = [\mathbb{P}(B^c)]^{n-1} \mathbb{P}(A \cap B) = [1 - \mathbb{P}(B)]^{n-1} \mathbb{P}(A \cap B) \quad (2.5.16)$$

Hence, using geometric series, the probability of the union is

$$\sum_{n=1}^{\infty} [1 - \mathbb{P}(B)]^{n-1} \mathbb{P}(A \cap B) = \frac{\mathbb{P}(A \cap B)}{1 - [1 - \mathbb{P}(B)]} = \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)} \quad (2.5.17)$$

Heuristic Argument

Suppose that we create a new experiment by repeating the basic experiment until B occurs for the first time, and then record the outcome of just the last repetition of the basic experiment. Now the set of outcomes is simply B and the appropriate probability measure on the new experiment is $A \mapsto \mathbb{P}(A | B)$.

Suppose that A and B are disjoint events in a basic experiment with $\mathbb{P}(A) > 0$ and $\mathbb{P}(B) > 0$. In the compound experiment obtained by replicating the basic experiment, the event that “ A occurs before B ” has probability

$$\frac{\mathbb{P}(A)}{\mathbb{P}(A) + \mathbb{P}(B)} \quad (2.5.18)$$

Proof

Note that the event “ A occurs before B ” is the same as the event “when $A \cup B$ occurs for the first time, A occurs”.

Examples and Applications

Basic Rules

Suppose that A , B , and C are independent events in an experiment with $\mathbb{P}(A) = 0.3$, $\mathbb{P}(B) = 0.4$, and $\mathbb{P}(C) = 0.8$. Express each of the following events in set notation and find its probability:

1. All three events occur.
2. None of the three events occurs.
3. At least one of the three events occurs.
4. At least one of the three events does not occur.
5. Exactly one of the three events occurs.
6. Exactly two of the three events occurs.

Answer

1. $\mathbb{P}(A \cap B \cap C) = 0.096$
2. $\mathbb{P}(A^c \cap B^c \cap C^c) = 0.084$
3. $\mathbb{P}(A \cup B \cup C) = 0.916$
4. $\mathbb{P}(A^c \cup B^c \cup C^c) = 0.904$
5. $\mathbb{P}[(A \cap B^c \cap C^c) \cup (A^c \cap B \cap C^c) \cup (A^c \cap B^c \cap C)] = 0.428$
6. $\mathbb{P}[(A \cap B \cap C^c) \cup (A \cap B^c \cap C) \cup (A^c \cap B \cap C)] = 0.392$

Suppose that A , B , and C are independent events for an experiment with $\mathbb{P}(A) = \frac{1}{3}$, $\mathbb{P}(B) = \frac{1}{4}$, and $\mathbb{P}(C) = \frac{1}{5}$. Find the probability of each of the following events:

1. $(A \cap B) \cup C$
2. $A \cup B^c \cup C$
3. $(A^c \cap B^c) \cup C^c$

Answer

1. $\frac{4}{15}$
2. $\frac{13}{15}$
3. $\frac{9}{10}$

Simple Populations

A small company has 100 employees; 40 are men and 60 are women. There are 6 male executives. How many female executives should there be if gender and rank are independent? The underlying experiment is to choose an employee at random.

Answer

9

Suppose that a farm has four orchards that produce peaches, and that peaches are classified by size as small, medium, and large. The table below gives total number of peaches in a recent harvest by orchard and by size. Fill in the body of the table with counts for the various intersections, so that orchard and size are independent variables. The underlying experiment is to select a peach at random from the farm.

Frequency	Size Small	Medium	Large	Total
Orchard 1			Total2000	400
2			Total2000	600
3			Total2000	300
4			Total2000	700
Total	400	1000	600	2000

Answer

Frequency	Size Small	Medium	Large	Total
-----------	------------	--------	-------	-------

Orchard 1	80	200	120	400
2	120	300	180	600
3	60	150	90	300
4	140	350	210	700
total	400	1000	600	2000

Note from the last two exercises that you cannot “see” independence in a Venn diagram. Again, independence is a measure-theoretic concept, not a set-theoretic concept.

Bernoulli Trials

A *Bernoulli trials sequence* is a sequence $\mathbf{X} = (X_1, X_2, \dots)$ of independent, identically distributed indicator variables. Random variable X_i is the outcome of trial i , where in the usual terminology of reliability theory, 1 denotes *success* and 0 denotes *failure*. The canonical example is the sequence of scores when a coin (not necessarily fair) is tossed repeatedly. Another basic example arises whenever we start with an basic experiment and an event A of interest, and then repeat the experiment. In this setting, X_i is the indicator variable for event A on the i th run of the experiment. The Bernoulli trials process is named for Jacob Bernoulli, and has a single basic *parameter* $p = \mathbb{P}(X_i = 1)$. This random process is studied in detail in the chapter on Bernoulli trials.

For $(x_1, x_2, \dots, x_n) \in \{0, 1\}^n$,

$$\mathbb{P}(X_1 = x_1, X_2 = x_2, \dots, X_n = x_n) = p^{x_1 + x_2 + \dots + x_n} (1 - p)^{n - (x_1 + x_2 + \dots + x_n)} \quad (2.5.19)$$

Proof

If X is a generic Bernoulli trial, then by definition, $\mathbb{P}(X = 1) = p$ and $\mathbb{P}(X = 0) = 1 - p$. Equivalently, $\mathbb{P}(X = x) = p^x (1 - p)^{1-x}$ for $x \in \{0, 1\}$. Thus the result follows by independence.

Note that the sequence of indicator random variables \mathbf{X} is exchangeable. That is, if the sequence (x_1, x_2, \dots, x_n) in the previous result is permuted, the probability does not change. On the other hand, there are exchangeable sequences of indicator random variables that are dependent, as Pólya's urn model so dramatically illustrates.

Let Y denote the number of successes in the first n trials. Then

$$\mathbb{P}(Y = y) = \binom{n}{y} p^y (1 - p)^{n-y}, \quad y \in \{0, 1, \dots, n\} \quad (2.5.20)$$

Proof

Note that $Y = \sum_{i=1}^n X_i$, where X_i is the outcome of trial i , as in the previous result. For $y \in \{0, 1, \dots, n\}$, the event $\{Y = y\}$ occurs if and only if exactly y of the n trials result in success (1). The number of ways to choose the y trials that result in success is $\binom{n}{y}$, and by the previous result, the probability of any particular sequence of y successes and $n - y$ failures is $p^y (1 - p)^{n-y}$. Thus the result follows by the additivity of probability.

The distribution of Y is called the *binomial distribution* with parameters n and p . The binomial distribution is studied in more detail in the chapter on Bernoulli Trials.

More generally, a *multinomial trials sequence* is a sequence $\mathbf{X} = (X_1, X_2, \dots)$ of independent, identically distributed random variables, each taking values in a finite set S . The canonical example is the sequence of scores when a k -sided die (not necessarily fair) is thrown repeatedly. Multinomial trials are also studied in detail in the chapter on Bernoulli trials.

Cards

Consider the experiment that consists of dealing 2 cards at random from a standard deck and recording the sequence of cards dealt. For $i \in \{1, 2\}$, let Q_i be the event that card i is a queen and H_i the event that card i is a heart. Compute the appropriate probabilities to verify the following results. Reflect on these results.

1. Q_1 and H_1 are independent.
2. Q_2 and H_2 are independent.
3. Q_1 and Q_2 are negatively correlated.

4. H_1 and H_2 are negatively correlated.
5. Q_1 and H_2 are independent.
6. H_1 and Q_2 are independent.

Answer

1. $\mathbb{P}(Q_1) = \mathbb{P}(Q_1 | H_1) = \frac{1}{13}$
2. $\mathbb{P}(Q_2) = \mathbb{P}(Q_2 | H_2) = \frac{1}{13}$
3. $\mathbb{P}(Q_1) = \frac{1}{13}$, $\mathbb{P}(Q_1 | Q_2) = \frac{1}{17}$
4. $\mathbb{P}(H_1) = \frac{1}{4}$, $\mathbb{P}(H_1 | H_2) = \frac{4}{17}$
5. $\mathbb{P}(Q_1) = \mathbb{P}(Q_1 | H_2) = \frac{1}{13}$
6. $\mathbb{P}(Q_2) = \mathbb{P}(Q_2 | H_1) = \frac{1}{13}$

In the card experiment, set $n = 2$. Run the simulation 500 times. For each pair of events in the previous exercise, compute the product of the empirical probabilities and the empirical probability of the intersection. Compare the results.

Dice

The following exercise gives three events that are *pairwise independent*, but not (*mutually*) *independent*.

Consider the dice experiment that consists of rolling 2 standard, fair dice and recording the sequence of scores. Let A denote the event that first score is 3, B the event that the second score is 4, and C the event that the sum of the scores is 7. Then

1. A , B , C are pairwise independent.
2. $A \cap B$ implies (is a subset of) C and hence these events are dependent in the strongest possible sense.

Answer

Note that $A \cap B = A \cap C = B \cap C = \{(3, 4)\}$, and the probability of the common intersection is $\frac{1}{36}$. On the other hand, $\mathbb{P}(A) = \mathbb{P}(B) = \mathbb{P}(C) = \frac{6}{36} = \frac{1}{6}$.

In the dice experiment, set $n = 2$. Run the experiment 500 times. For each pair of events in the previous exercise, compute the product of the empirical probabilities and the empirical probability of the intersection. Compare the results.

The following exercise gives an example of three events with the property that the probability of the intersection is the product of the probabilities, but the events are not pairwise independent.

Suppose that we throw a standard, fair die one time. Let $A = \{1, 2, 3, 4\}$, $B = C = \{4, 5, 6\}$. Then

1. $\mathbb{P}(A \cap B \cap C) = \mathbb{P}(A)\mathbb{P}(B)\mathbb{P}(C)$.
2. B and C are the same event, and hence are dependent in the strongest possible sense.

Answer

Note that $A \cap B \cap C = \{4\}$, so $\mathbb{P}(A \cap B \cap C) = \frac{1}{6}$. On the other hand, $\mathbb{P}(A) = \frac{4}{6}$ and $\mathbb{P}(B) = \mathbb{P}(C) = \frac{3}{6}$.

Suppose that a standard, fair die is thrown 4 times. Find the probability of the following events.

1. Six does not occur.
2. Six occurs at least once.
3. The sum of the first two scores is 5 and the sum of the last two scores is 7.

Answer

1. $\left(\frac{5}{6}\right)^4 \approx 0.4823$
2. $1 - \left(\frac{5}{6}\right)^4 \approx 0.5177$
3. $\frac{1}{54}$

Suppose that a pair of standard, fair dice are thrown 8 times. Find the probability of each of the following events.

1. Double six does not occur.
2. Double six occurs at least once.

3. Double six does not occur on the first 4 throws but occurs at least once in the last 4 throws.

Answer

1. $\left(\frac{35}{36}\right)^8 \approx 0.7982$
2. $1 - \left(\frac{35}{36}\right)^8 \approx 0.2018$
3. $\left(\frac{35}{36}\right)^4 \left[1 - \left(\frac{35}{36}\right)^4\right] \approx 0.0952$

Consider the dice experiment that consists of rolling n , k -sided dice and recording the sequence of scores $\mathbf{X} = (X_1, X_2, \dots, X_n)$. The following conditions are equivalent (and correspond to the assumption that the dice are fair):

1. \mathbf{X} is uniformly distributed on $\{1, 2, \dots, k\}^n$.
2. \mathbf{X} is a sequence of independent variables, and X_i is uniformly distributed on $\{1, 2, \dots, k\}$ for each i .

Proof

Let $S = \{1, 2, \dots, k\}$ and note that S^n has k^n points. Suppose that \mathbf{X} is uniformly distributed on S^n . Then $\mathbb{P}(\mathbf{X} = \mathbf{x}) = 1/k^n$ for each $\mathbf{x} \in S^n$ so $\mathbb{P}(X_i = x) = k^{n-1}/k^n = 1/k$ for each $x \in S$. Hence X_i is uniformly distributed on S . Moreover,

$$\mathbb{P}(\mathbf{X} = \mathbf{x}) = \mathbb{P}(X_1 = x_1)\mathbb{P}(X_2 = x_2) \cdots \mathbb{P}(X_n = x_n), \quad \mathbf{x} = (x_1, x_2, \dots, x_n) \in S^n \quad (2.5.21)$$

so \mathbf{X} is an independent sequence. Conversely, if \mathbf{X} is an independent sequence and X_i is uniformly distributed on S for each i then $\mathbb{P}(X_i = x) = 1/k$ for each $x \in S$ and hence $\mathbb{P}(\mathbf{X} = \mathbf{x}) = 1/k^n$ for each $\mathbf{x} \in S^n$. Thus \mathbf{X} is uniformly distributed on S^n .

A pair of standard, fair dice are thrown repeatedly. Find the probability of each of the following events.

1. A sum of 4 occurs before a sum of 7.
2. A sum of 5 occurs before a sum of 7.
3. A sum of 6 occurs before a sum of 7.
4. When a sum of 8 occurs the first time, it occurs “the hard way” as $(4, 4)$.

Answer

1. $\frac{3}{9}$
2. $\frac{4}{10}$
3. $\frac{5}{11}$
4. $\frac{1}{5}$

Problems of the type in the last exercise are important in the game of *craps*. Craps is studied in more detail in the chapter on Games of Chance.

Coins

A biased coin with probability of heads $\frac{1}{3}$ is tossed 5 times. Let \mathbf{X} denote the outcome of the tosses (encoded as a bit string) and let Y denote the number of heads. Find each of the following:

1. $\mathbb{P}(\mathbf{X} = \mathbf{x})$ for each $\mathbf{x} \in \{0, 1\}^5$.
2. $\mathbb{P}(Y = y)$ for each $y \in \{0, 1, 2, 3, 4, 5\}$
3. $\mathbb{P}(1 \leq Y \leq 3)$

Answer

1. $\frac{32}{243}$ if $\mathbf{x} = 00000$, $\frac{16}{243}$ if \mathbf{x} has exactly one 1 (there are 5 of these), $\frac{8}{243}$ if \mathbf{x} has exactly two 1s (there are 10 of these), $\frac{4}{243}$ if \mathbf{x} has exactly three 1s (there are 10 of these), $\frac{2}{243}$ if \mathbf{x} has exactly four 1s (there are 5 of these), $\frac{1}{243}$ if $\mathbf{x} = 11111$
2. $\frac{32}{243}$ if $y = 0$, $\frac{80}{243}$ if $y = 1$, $\frac{80}{243}$ if $y = 2$, $\frac{40}{243}$ if $y = 3$, $\frac{10}{243}$ if $y = 4$, $\frac{1}{243}$ if $y = 5$
3. $\frac{200}{243}$

A box contains a fair coin and a two-headed coin. A coin is chosen at random from the box and tossed repeatedly. Let F denote the event that the fair coin is chosen, and let H_i denote the event that the i th toss results in heads. Then

1. (H_1, H_2, \dots) are conditionally independent given F , with $\mathbb{P}(H_i | F) = \frac{1}{2}$ for each i .
2. (H_1, H_2, \dots) are conditionally independent given F^c , with $\mathbb{P}(H_i | F^c) = 1$ for each i .

3. $\mathbb{P}(H_i) = \frac{3}{4}$ for each i .
4. $\mathbb{P}(H_1 \cap H_2 \cap \dots \cap H_n) = \frac{1}{2^{n+1}} + \frac{1}{2}$.
5. (H_1, H_2, \dots) are dependent.
6. $\mathbb{P}(F | H_1 \cap H_2 \cap \dots \cap H_n) = \frac{1}{2^{n+1}}$.
7. $\mathbb{P}(F | H_1 \cap H_2 \cap \dots \cap H_n) \rightarrow 0$ as $n \rightarrow \infty$.

Proof

Parts (a) and (b) are essentially modeling assumptions, based on the design of the experiment. If we know what kind of coin we have, then the tosses are independent. Parts (c) and (d) follow by conditioning on the type of coin and using parts (a) and (b). Part (e) follows from (c) and (d). Note that the expression in (d) is not $(3/4)^n$. Part (f) follows from part (d) and Bayes' theorem. Finally part (g) follows from part (f).

Consider again the box in the previous exercise, but we change the experiment as follows: a coin is chosen at random from the box and tossed and the result recorded. The coin is returned to the box and the process is repeated. As before, let H_i denote the event that toss i results in heads. Then

1. (H_1, H_2, \dots) are independent.
2. $\mathbb{P}(H_i) = \frac{3}{4}$ for each i .
3. $\mathbb{P}(H_1 \cap H_2 \cap \dots \cap H_n) = \left(\frac{3}{4}\right)^n$.

Proof

Again, part (a) is essentially a modeling assumption. Since we return the coin and draw a new coin at random each time, the results of the tosses should be independent. Part (b) follows by conditioning on the type of the i th coin. Part (c) follows from parts (a) and (b).

Think carefully about the results in the previous two exercises, and the differences between the two models. Tossing a coin produces independent random variables *if* the probability of heads is fixed (that is, non-random even if unknown). Tossing a coin with a random probability of heads generally does not produce independent random variables; the result of a toss gives information about the probability of heads which in turn gives information about subsequent tosses.

Uniform Distributions

Recall that Buffon's coin experiment consists of tossing a coin with radius $r \leq \frac{1}{2}$ randomly on a floor covered with square tiles of side length 1. The coordinates (X, Y) of the center of the coin are recorded relative to axes through the center of the square in which the coin lands. The following conditions are equivalent:

1. (X, Y) is uniformly distributed on $[-\frac{1}{2}, \frac{1}{2}]^2$.
2. X and Y are independent and each is uniformly distributed on $[-\frac{1}{2}, \frac{1}{2}]$.

Figure 2.5.1: Buffon's coin experiment

Proof

Let $S = [-\frac{1}{2}, \frac{1}{2}]$, and let λ_1 denote length measure on S and λ_2 area measure on S^2 . Note that $\lambda_1(S) = \lambda_2(S^2) = 1$. Suppose that (X, Y) is uniformly distributed on S^2 , so that $\mathbb{P}[(X, Y) \in C] = \lambda_2(C)$ for $C \subseteq S^2$. For $A \subseteq S$,

$$\mathbb{P}(X \in A) = \mathbb{P}[(X, Y) \in A \times S] = \lambda_2(A \times S) = \lambda_1(A) \quad (2.5.22)$$

Hence X is uniformly distributed on S . By a similar argument, Y is also uniformly distributed on S . Moreover, for $A \subseteq S$ and $B \subseteq S$,

$$\mathbb{P}(X \in A, Y \in B) = \mathbb{P}[(X, Y) \in A \times B] = \lambda_2(A \times B) = \lambda_1(A)\lambda_1(B) = \mathbb{P}(X \in A)\mathbb{P}(Y \in B) \quad (2.5.23)$$

so X and Y are independent. Conversely, if X and Y are independent and each is uniformly distributed on S , then for $A \subseteq S$ and $B \subseteq S$,

$$\mathbb{P}[(X, Y) \in A \times B] = \mathbb{P}(X \in A)\mathbb{P}(Y \in B) = \lambda_1(A)\lambda_1(B) = \lambda_2(A \times B) \quad (2.5.24)$$

It then follows that $\mathbb{P}[(X, Y) \in C] = \lambda_2(C)$ for every $C \subseteq S^2$. For more details about this last step, see the advanced section on existence and uniqueness of measures.

Compare this result with the result above for [fair dice](#).

In Buffon's coin experiment, set $r = 0.3$. Run the simulation 500 times. For the events $\{X > 0\}$ and $\{Y < 0\}$, compute the product of the empirical probabilities and the empirical probability of the intersection. Compare the results.

The arrival time X of the A train is uniformly distributed on the interval $(0, 30)$, while the arrival time Y of the B train is uniformly distributed on the interval $(15, 30)$. (The arrival times are in minutes, after 8:00 AM). Moreover, the arrival times are independent. Find the probability of each of the following events:

1. The A train arrives first.
2. Both trains arrive sometime after 20 minutes.

Answer

1. $\frac{3}{4}$
2. $\frac{2}{9}$

Reliability

Recall the simple model of structural reliability in which a system is composed of n components. Suppose in addition that the components operate independently of each other. As before, let X_i denote the state of component i , where 1 means working and 0 means failure. Thus, our basic assumption is that the *state vector* $\mathbf{X} = (X_1, X_2, \dots, X_n)$ is a sequence of independent indicator random variables. We assume that the state of the system (either working or failed) depends only on the states of the components. Thus, the state of the system is an indicator random variable

$$Y = y(X_1, X_2, \dots, X_n) \quad (2.5.25)$$

where $y : \{0, 1\}^n \rightarrow \{0, 1\}$ is the *structure function*. Generally, the probability that a device is working is the *reliability* of the device. Thus, we will denote the reliability of component i by $p_i = \mathbb{P}(X_i = 1)$ so that the vector of component reliabilities is $\mathbf{p} = (p_1, p_2, \dots, p_n)$. By independence, the system reliability r is a function of the component reliabilities:

$$r(p_1, p_2, \dots, p_n) = \mathbb{P}(Y = 1) \quad (2.5.26)$$

Appropriately enough, this function is known as the *reliability function*. Our challenge is usually to find the reliability function, given the structure function. When the components all have the same probability p then of course the system reliability r is just a function of p . In this case, the state vector $\mathbf{X} = (X_1, X_2, \dots, X_n)$ forms a sequence of [Bernoulli trials](#).

Comment on the independence assumption for real systems, such as your car or your computer.

Recall that a *series system* is working if and only if each component is working.

1. The state of the system is $U = X_1 X_2 \cdots X_n = \min\{X_1, X_2, \dots, X_n\}$.
2. The reliability is $\mathbb{P}(U = 1) = p_1 p_2 \cdots p_n$.

Recall that a *parallel system* is working if and only if at least one component is working.

1. The state of the system is $V = 1 - (1 - X_1)(1 - X_2) \cdots (1 - X_n) = \max\{X_1, X_2, \dots, X_n\}$.
2. The reliability is $\mathbb{P}(V = 1) = 1 - (1 - p_1)(1 - p_2) \cdots (1 - p_n)$.

Recall that a *k out of n system* is working if and only if at least k of the n components are working. Thus, a parallel system is a 1 out of n system and a series system is an n out of n system. A k out of $2k - 1$ system is a *majority rules system*. The reliability function of a general k out of n system is a mess. However, if the component reliabilities are the same, the function has a reasonably simple form.

For a k out of n system with common component reliability p , the system reliability is

$$r(p) = \sum_{i=k}^n \binom{n}{i} p^i (1-p)^{n-i} \quad (2.5.27)$$

Consider a system of 3 independent components with common reliability $p = 0.8$. Find the reliability of each of the following:

1. The parallel system.
2. The 2 out of 3 system.
3. The series system.

Answer

1. 0.992
2. 0.896
3. 0.512

Consider a system of 3 independent components with reliabilities $p_1 = 0.8$, $p_2 = 0.8$, $p_3 = 0.7$. Find the reliability of each of the following:

1. The parallel system.
2. The 2 out of 3 system.
3. The series system.

Answer

1. 0.994
2. 0.902
3. 0.504

Consider an airplane with an odd number of engines, each with reliability p . Suppose that the airplane is a majority rules system, so that the airplane needs a majority of working engines in order to fly.

1. Find the reliability of a 3 engine plane as a function of p .
2. Find the reliability of a 5 engine plane as a function of p .
3. For what values of p is a 5 engine plane preferable to a 3 engine plane?

Answer

1. $r_3(p) = 3p^2 - 2p^3$
2. $r_5(p) = 6p^5 - 15p^4 + 10p^3$
3. The 5-engine plane would be preferable if $p > \frac{1}{2}$ (which one would hope would be the case). The 3-engine plane would be preferable if $p < \frac{1}{2}$. If $p = \frac{1}{2}$, the 3-engine and 5-engine planes are equally reliable.

The graph below is known as the *Wheatstone bridge network* and is named for Charles Wheatstone. The edges represent components, and the system works if and only if there is a working path from vertex a to vertex b .

1. Find the structure function.
2. Find the reliability function.

Figure 2.5.2: The Wheatstone bridge network

Answer

1. $Y = X_3(X_1 + X_2 - X_1X_2)(X_4 + X_5 - X_4X_5) + (1 - X_3)(X_1X_4 + X_2X_5 - X_1X_2X_4X_5)$
2. $r(p_1, p_2, p_3, p_4, p_5) = p_3(p_1 + p_2 - p_1p_2)(p_4 + p_5 - p_4p_5) + (1 - p_3)(p_1p_4 + p_2p_5 - p_1p_2p_4p_5)$

A system consists of 3 components, connected in parallel. Because of environmental factors, the components do not operate independently, so our usual assumption does not hold. However, we will assume that under low stress conditions, the components are independent, each with reliability 0.9; under medium stress conditions, the components are independent with reliability 0.8; and under high stress conditions, the components are independent, each with reliability 0.7. The probability of low stress is 0.5, of medium stress is 0.3, and of high stress is 0.2.

1. Find the reliability of the system.
2. Given that the system works, find the conditional probability of each stress level.

Answer

1. 0.9917. Condition on the stress level.
2. 0.5037 for low, 0.3001 for medium, 0.1962 for high. Use Bayes' theorem and part (a).

Suppose that bits are transmitted across a noisy communications channel. Each bit that is sent, independently of the others, is received correctly with probability 0.9 and changed to the complementary bit with probability 0.1. Using redundancy to improve reliability, suppose that a given bit will be sent 3 times. We naturally want to compute the probability that we correctly identify the bit that was sent. Assume we have no prior knowledge of the bit, so we assign probability $\frac{1}{2}$ each to the event that 000 was sent and the event that 111 was sent. Now find the conditional probability that 111 was sent given each of the 8 possible bit strings received.

Answer

Let \mathbf{X} denote the string sent and \mathbf{Y} the string received.

\mathbf{y}	$\mathbb{P}(\mathbf{X} = 111 \mid \mathbf{Y} = \mathbf{y})$
111	729/730
110	9/10
101	9/10
011	9/10
100	1/10
010	1/10
001	1/10
000	1/730

Diagnostic Testing

Recall the discussion of diagnostic testing in the section on Conditional Probability. Thus, we have an event A for a random experiment whose occurrence or non-occurrence we cannot observe directly. Suppose now that we have n tests for the occurrence of A , labeled from 1 to n . We will let T_i denote the event that test i is positive for A . The tests are independent in the following sense:

- If A occurs, then (T_1, T_2, \dots, T_n) are (conditionally) independent and test i has sensitivity $a_i = \mathbb{P}(T_i \mid A)$.
- If A does not occur, then (T_1, T_2, \dots, T_n) are (conditionally) independent and test i has specificity $b_i = \mathbb{P}(T_i^c \mid A^c)$.

Note that *unconditionally*, it is not reasonable to assume that the tests are independent. For example, a positive result for a given test presumably is evidence that the condition A has occurred, which in turn is evidence that a subsequent test will be positive. In short, we expect that T_i and T_j should be positively correlated.

We can form a new, compound test by giving a *decision rule* in terms of the individual test results. In other words, the event T that the compound test is positive for A is a function of (T_1, T_2, \dots, T_n) . The typical decision rules are very similar to the [reliability structures](#) discussed above. A special case of interest is when the n tests are independent applications of a given basic test. In this case, $a_i = a$ and $b_i = b$ for each i .

Consider the compound test that is positive for A if and only if each of the n tests is positive for A .

1. $T = T_1 \cap T_2 \cap \dots \cap T_n$
2. The sensitivity is $\mathbb{P}(T \mid A) = a_1 a_2 \dots a_n$.
3. The specificity is $\mathbb{P}(T^c \mid A^c) = 1 - (1 - b_1)(1 - b_2) \dots (1 - b_n)$

Consider the compound test that is positive for A if and only if each at least one of the n tests is positive for A .

1. $T = T_1 \cup T_2 \cup \dots \cup T_n$
2. The sensitivity is $\mathbb{P}(T \mid A) = 1 - (1 - a_1)(1 - a_2) \dots (1 - a_n)$.
3. The specificity is $\mathbb{P}(T^c \mid A^c) = b_1 b_2 \dots b_n$.

More generally, we could define the compound k out of n test that is positive for A if and only if at least k of the individual tests are positive for A . The [series test](#) is the n out of n test, while the [parallel test](#) is the 1 out of n test. The k out of $2k - 1$ test is the *majority rules test*.

Suppose that a woman initially believes that there is an even chance that she is or is not pregnant. She buys three identical pregnancy tests with sensitivity 0.95 and specificity 0.90. Tests 1 and 3 are positive and test 2 is negative.

1. Find the updated probability that the woman is pregnant.
2. Can we just say that tests 2 and 3 cancel each other out? Find the probability that the woman is pregnant given just one positive test, and compare the answer with the answer to part (a).

Answer

1. 0.834
2. No: 0.905.

Suppose that 3 independent, identical tests for an event A are applied, each with sensitivity a and specificity b . Find the sensitivity and specificity of the following tests:

1. 1 out of 3 test
2. 2 out of 3 test
3. 3 out of 3 test

Answer

1. sensitivity $1 - (1 - a)^3$, specificity b^3
2. sensitivity $3a^2$, specificity $b^3 + 3b^2(1 - b)$
3. sensitivity a^3 , specificity $1 - (1 - b)^3$

In a criminal trial, the defendant is convicted if and only if all 6 jurors vote guilty. Assume that if the defendant really is guilty, the jurors vote guilty, independently, with probability 0.95, while if the defendant is really innocent, the jurors vote not guilty, independently with probability 0.8. Suppose that 70% of defendants brought to trial are guilty.

1. Find the probability that the defendant is convicted.
2. Given that the defendant is convicted, find the probability that the defendant is guilty.
3. Comment on the assumption that the jurors act independently.

Answer

1. 0.5148
2. 0.99996
3. The independence assumption is not reasonable since jurors collaborate.

Genetics

Please refer to the discussion of genetics in the section on random experiments if you need to review some of the definitions in this section.

Recall first that the *ABO blood type* in humans is determined by three alleles: a , b , and o . Furthermore, a and b are co-dominant and o is recessive. Suppose that in a certain population, the proportion of a , b , and o alleles are p , q , and r respectively. Of course we must have $p > 0$, $q > 0$, $r > 0$ and $p + q + r = 1$.

Suppose that the blood genotype in a person is the result of independent alleles, chosen with probabilities p , q , and r as above.

1. The probability distribution of the genotypes is given in the following table:

Genotype	aa	ab	ao	bb	bo	oo
Probability	p^2	$2pq$	$2pr$	q^2	$2qr$	r^2

2. The probability distribution of the blood types is given in the following table:

Blood type	A	B	AB	O
Probability	$p^2 + 2pr$	$q^2 + 2qr$	$2pq$	r^2

Proof

Part (a) follows from the independence assumption and basic rules of probability. Even though genotypes are listed as unordered pairs, note that there are two ways that a heterozygous genotype can occur, since either parent could contribute either of the two distinct alleles. Part (b) follows from part (a) and basic rules of probability.

The discussion above is related to the *Hardy-Weinberg model* of genetics. The model is named for the English mathematician Godfrey Hardy and the German physician Wilhelm Weiberg

Suppose that the probability distribution for the set of blood types in a certain population is given in the following table:

Blood type	A	B	AB	O
Probability	0.360	0.123	0.038	0.479

Find p , q , and r .

Answer

$$p = 0.224, q = 0.084, r = 0.692$$

Suppose next that pod color in certain type of pea plant is determined by a gene with two alleles: g for green and y for yellow, and that g is dominant and o recessive.

Suppose that 2 green-pod plants are bred together. Suppose further that each plant, independently, has the recessive yellow-pod allele with probability $\frac{1}{4}$.

1. Find the probability that 3 offspring plants will have green pods.
2. Given that the 3 offspring plants have green pods, find the updated probability that both parents have the recessive allele.

Answer

1. $\frac{987}{1024}$
2. $\frac{27}{987}$

Next consider a sex-linked hereditary disorder in humans (such as colorblindness or hemophilia). Let h denote the healthy allele and d the defective allele for the gene linked to the disorder. Recall that h is dominant and d recessive for women.

Suppose that a healthy woman initially has a $\frac{1}{2}$ chance of being a carrier. (This would be the case, for example, if her mother and father are healthy but she has a brother with the disorder, so that her mother must be a carrier).

1. Find the probability that the first two sons of the women will be healthy.
2. Given that the first two sons are healthy, compute the updated probability that she is a carrier.
3. Given that the first two sons are healthy, compute the conditional probability that the third son will be healthy.

Answer

1. $\frac{5}{8}$
2. $\frac{1}{5}$
3. $\frac{9}{10}$

Laplace's Rule of Succession

Suppose that we have $m + 1$ coins, labeled $0, 1, \dots, m$. Coin i lands heads with probability $\frac{i}{m}$ for each i . The experiment is to choose a coin at random (so that each coin is equally likely to be chosen) and then toss the chosen coin repeatedly.

1. The probability that the first n tosses are all heads is $p_{m,n} = \frac{1}{m+1} \sum_{i=0}^m \left(\frac{i}{m}\right)^n$
2. $p_{m,n} \rightarrow \frac{1}{n+1}$ as $m \rightarrow \infty$
3. The conditional probability that toss $n + 1$ is heads given that the previous n tosses were all heads is $\frac{p_{m,n+1}}{p_{m,n}}$
4. $\frac{p_{m,n+1}}{p_{m,n}} \rightarrow \frac{n+1}{n+2}$ as $m \rightarrow \infty$

Proof

Part (a) follows by conditioning on the chosen coin. For part (b), note that $p_{m,n}$ is an approximating sum for $\int_0^1 x^n dx = \frac{1}{n+1}$. Part (c) follows from the definition of conditional probability, and part (d) is a trivial consequence of (b), (c).

Note that coin 0 is two-tailed, the probability of heads increases with i , and coin m is two-headed. The limiting conditional probability in part (d) is called *Laplace's Rule of Succession*, named after Simon Laplace. This rule was used by Laplace and others as a general principle for estimating the conditional probability that an event will occur on time $n + 1$, given that the event has occurred n times in succession.

Suppose that a missile has had 10 successful tests in a row. Compute Laplace's estimate that the 11th test will be successful. Does this make sense?

Answer

$\frac{11}{12}$. No, not really.

This page titled [2.5: Independence](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist \(Random Services\)](#) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

2.6: Convergence

This is the first of several sections in this chapter that are more advanced than the basic topics in the first five sections. In this section we discuss several topics related to convergence of events and random variables, a subject of fundamental importance in probability theory. In particular the results that we obtain will be important for:

- Properties of distribution functions,
- The weak law of large numbers,
- The strong law of large numbers.

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} the σ -algebra of events, and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) .

Basic Theory

Sequences of events

Our first discussion deals with sequences of events and various types of limits of such sequences. The limits are also event. We start with two simple definitions.

Suppose that (A_1, A_2, \dots) is a sequence of events.

1. The sequence is *increasing* if $A_n \subseteq A_{n+1}$ for every $n \in \mathbb{N}_+$.
2. The sequence is *decreasing* if $A_{n+1} \subseteq A_n$ for every $n \in \mathbb{N}_+$.

Note that these are the standard definitions of increasing and decreasing, relative to the ordinary total order \leq on the index set \mathbb{N}_+ and the subset partial order \subseteq on the collection of events. The terminology is also justified by the corresponding indicator variables.

Suppose that (A_1, A_2, \dots) is a sequence of events, and let $I_n = \mathbf{1}_{A_n}$ denote the indicator variable of the event A_n for $n \in \mathbb{N}_+$.

1. The sequence of events is increasing if and only if the sequence of indicator variables is increasing in the ordinary sense. That is, $I_n \leq I_{n+1}$ for each $n \in \mathbb{N}_+$.
2. The sequence of events is decreasing if and only if the sequence of indicator variables is decreasing in the ordinary sense. That is, $I_{n+1} \leq I_n$ for each $n \in \mathbb{N}_+$.

Proof

Figure 2.6.1: A sequence of increasing events and their union

Figure 2.6.2: A sequence of decreasing events and their intersection

If a sequence of events is either increasing or decreasing, we can define the *limit* of the sequence in a way that turns out to be quite natural.

Suppose that (A_1, A_2, \dots) is a sequence of events.

1. If the sequence is increasing, we define $\lim_{n \rightarrow \infty} A_n = \bigcup_{n=1}^{\infty} A_n$.
2. If the sequence is decreasing, we define $\lim_{n \rightarrow \infty} A_n = \bigcap_{n=1}^{\infty} A_n$.

Once again, the terminology is clarified by the corresponding indicator variables.

Suppose again that (A_1, A_2, \dots) is a sequence of events, and let $I_n = \mathbf{1}_{A_n}$ denote the indicator variable of A_n for $n \in \mathbb{N}_+$.

1. If the sequence of events is increasing, then $\lim_{n \rightarrow \infty} I_n$ is the indicator variable of $\bigcup_{n=1}^{\infty} A_n$
2. If the sequence of events is decreasing, then $\lim_{n \rightarrow \infty} I_n$ is the indicator variable of $\bigcap_{n=1}^{\infty} A_n$

Proof

1. If $s \in \bigcup_{n=1}^{\infty} A_n$ then $s \in A_k$ for some $k \in \mathbb{N}_+$. Since the events are increasing, $s \in A_n$ for every $n \geq k$. In this case, $I_n(s) = 1$ for every $n \geq k$ and hence $\lim_{n \rightarrow \infty} I_n(s) = 1$. On the other hand, if $s \notin \bigcup_{n=1}^{\infty} A_n$ then $s \notin A_n$ for every $n \in \mathbb{N}_+$. In this case, $I_n(s) = 0$ for every $n \in \mathbb{N}_+$ and hence $\lim_{n \rightarrow \infty} I_n(s) = 0$.
2. If $s \in \bigcap_{n=1}^{\infty} A_n$ then $s \in A_n$ for each $n \in \mathbb{N}_+$. In this case, $I_n(s) = 1$ for each $n \in \mathbb{N}_+$ and hence $\lim_{n \rightarrow \infty} I_n(s) = 1$. If $s \notin \bigcap_{n=1}^{\infty} A_n$ then $s \notin A_k$ for some $k \in \mathbb{N}_+$. Since the events are decreasing, $s \notin A_n$ for all $n \geq k$. In this case, $I_n(s) = 0$ for $n \geq k$ and hence $\lim_{n \rightarrow \infty} I_n(s) = 0$.

An arbitrary union of events can always be written as a union of increasing events, and an arbitrary intersection of events can always be written as an intersection of decreasing events:

Suppose that (A_1, A_2, \dots) is a sequence of events. Then

1. $\bigcup_{i=1}^n A_i$ is increasing in $n \in \mathbb{N}_+$ and $\bigcup_{i=1}^{\infty} A_i = \lim_{n \rightarrow \infty} \bigcup_{i=1}^n A_i$.
2. $\bigcap_{i=1}^n A_i$ is decreasing in $n \in \mathbb{N}_+$ and $\bigcap_{i=1}^{\infty} A_i = \lim_{n \rightarrow \infty} \bigcap_{i=1}^n A_i$.

Proof

1. Trivially $\bigcup_{i=1}^n A_i \subseteq \bigcup_{i=1}^{n+1} A_i$. The second statement simply means that $\bigcup_{n=1}^{\infty} \bigcup_{i=1}^n A_i = \bigcup_{i=1}^{\infty} A_i$.
2. Trivially $\bigcap_{i=1}^{n+1} A_i \subseteq \bigcap_{i=1}^n A_i$. The second statement simply means that $\bigcap_{n=1}^{\infty} \bigcap_{i=1}^n A_i = \bigcap_{i=1}^{\infty} A_i$.

There is a more interesting and useful way to generate increasing and decreasing sequences from an arbitrary sequence of events, using the *tail* segment of the sequence rather than the *initial* segment.

Suppose that (A_1, A_2, \dots) is a sequence of events. Then

1. $\bigcup_{i=n}^{\infty} A_i$ is decreasing in $n \in \mathbb{N}_+$.
2. $\bigcap_{i=n}^{\infty} A_i$ is increasing in $n \in \mathbb{N}_+$.

Proof

1. Clearly $\bigcup_{i=n+1}^{\infty} A_i \subseteq \bigcup_{i=n}^{\infty} A_i$
2. Clearly $\bigcap_{i=n}^{\infty} A_i \subseteq \bigcap_{i=n+1}^{\infty} A_i$

Since the new sequences defined in the previous results are decreasing and increasing, respectively, we can take their limits. These are the *limit superior* and *limit inferior*, respectively, of the original sequence.

Suppose that (A_1, A_2, \dots) is a sequence of events. Define

1. $\limsup_{n \rightarrow \infty} A_n = \lim_{n \rightarrow \infty} \bigcup_{i=n}^{\infty} A_i = \bigcap_{n=1}^{\infty} \bigcup_{i=n}^{\infty} A_i$. This is the event that occurs if and only if A_n occurs for infinitely many values of n .
2. $\liminf_{n \rightarrow \infty} A_n = \lim_{n \rightarrow \infty} \bigcap_{i=n}^{\infty} A_i = \bigcup_{n=1}^{\infty} \bigcap_{i=n}^{\infty} A_i$. This is the event that occurs if and only if A_n occurs for all but finitely many values of n .

Proof

1. From the definition, the event $\limsup_{n \rightarrow \infty} A_n$ occurs if and only if for each $n \in \mathbb{N}_+$ there exists $i \geq n$ such that A_i occurs.
2. From the definition, the event $\liminf_{n \rightarrow \infty} A_n$ occurs if and only if there exists $n \in \mathbb{N}_+$ such that A_i occurs for every $i \geq n$.

Once again, the terminology and notation are clarified by the corresponding indicator variables. You may need to review limit inferior and limit superior for sequences of real numbers in the section on Partial Orders.

Suppose that (A_1, A_2, \dots) is a sequence of events, and let $I_n = \mathbf{1}_{A_n}$ denote the indicator variable of A_n for $n \in \mathbb{N}_+$. Then

1. $\limsup_{n \rightarrow \infty} I_n$ is the indicator variable of $\limsup_{n \rightarrow \infty} A_n$.
2. $\liminf_{n \rightarrow \infty} I_n$ is the indicator variable of $\liminf_{n \rightarrow \infty} A_n$.

Proof

1. By the result above, $\lim_{n \rightarrow \infty} \mathbf{1}(\bigcup_{i=n}^{\infty} A_i)$ is the indicator variable of $\limsup_{n \rightarrow \infty} A_n$. But $\mathbf{1}(\bigcup_{i=n}^{\infty} A_i) = \max\{I_i : i \geq n\}$ and hence $\lim_{n \rightarrow \infty} \mathbf{1}(\bigcup_{i=n}^{\infty} A_i) = \limsup_{n \rightarrow \infty} I_n$.
2. By the result above, $\lim_{n \rightarrow \infty} \mathbf{1}(\bigcap_{i=n}^{\infty} A_i)$ is the indicator variable of $\liminf_{n \rightarrow \infty} A_n$. But $\mathbf{1}(\bigcap_{i=n}^{\infty} A_i) = \min\{I_i : i \geq n\}$ and hence $\lim_{n \rightarrow \infty} \mathbf{1}(\bigcap_{i=n}^{\infty} A_i) = \liminf_{n \rightarrow \infty} I_n$.

Suppose that (A_1, A_2, \dots) is a sequence of events. Then $\liminf_{n \rightarrow \infty} A_n \subseteq \limsup_{n \rightarrow \infty} A_n$.

Proof

If A_n occurs for all but finitely many $n \in \mathbb{N}_+$ then certainly A_n occurs for infinitely many $n \in \mathbb{N}_+$.

Suppose that (A_1, A_2, \dots) is a sequence of events. Then

1. $(\limsup_{n \rightarrow \infty} A_n)^c = \liminf_{n \rightarrow \infty} A_n^c$
2. $(\liminf_{n \rightarrow \infty} A_n)^c = \limsup_{n \rightarrow \infty} A_n^c$.

Proof

These results follow from DeMorgan's laws.

The Continuity Theorems

Generally speaking, a function is *continuous* if it preserves limits. Thus, the following results are the *continuity theorems of probability*. Part (a) is the continuity theorem for increasing events and part (b) the continuity theorem for decreasing events.

Suppose that (A_1, A_2, \dots) is a sequence of events.

1. If the sequence is increasing then $\lim_{n \rightarrow \infty} \mathbb{P}(A_n) = \mathbb{P}(\lim_{n \rightarrow \infty} A_n) = \mathbb{P}(\bigcup_{n=1}^{\infty} A_n)$
2. If the sequence is decreasing then $\lim_{n \rightarrow \infty} \mathbb{P}(A_n) = \mathbb{P}(\lim_{n \rightarrow \infty} A_n) = \mathbb{P}(\bigcap_{n=1}^{\infty} A_n)$

Proof

1. Let $B_1 = A_1$ and let $B_i = A_i \setminus A_{i-1}$ for $i \in \{2, 3, \dots\}$. Note that the collection of events $\{B_1, B_2, \dots\}$ is pairwise disjoint and has the same union as $\{A_1, A_2, \dots\}$. From countable additivity and the definition of infinite series,

$$\mathbb{P}\left(\bigcup_{i=1}^{\infty} A_i\right) = \mathbb{P}\left(\bigcup_{i=1}^{\infty} B_i\right) = \sum_{i=1}^{\infty} \mathbb{P}(B_i) = \lim_{n \rightarrow \infty} \sum_{i=1}^n \mathbb{P}(B_i) \quad (2.6.1)$$

But $\mathbb{P}(B_1) = \mathbb{P}(A_1)$ and $\mathbb{P}(B_i) = \mathbb{P}(A_i) - \mathbb{P}(A_{i-1})$ for $i \in \{2, 3, \dots\}$. Therefore $\sum_{i=1}^n \mathbb{P}(B_i) = \mathbb{P}(A_n)$ and hence we have $\mathbb{P}(\bigcup_{i=1}^{\infty} A_i) = \lim_{n \rightarrow \infty} \mathbb{P}(A_n)$.

The construction in the continuity theorem for increasing events

 The construction in the continuity theorem

2. The sequence of complements (A_1^c, A_2^c, \dots) is increasing. Hence using part (a), DeMorgan's law, and the complement rule we have

$$\mathbb{P}\left(\bigcap_{i=1}^{\infty} A_i\right) = 1 - \mathbb{P}\left(\bigcup_{i=1}^{\infty} A_i^c\right) = 1 - \lim_{n \rightarrow \infty} \mathbb{P}(A_n^c) = \lim_{n \rightarrow \infty} [1 - \mathbb{P}(A_n^c)] = \lim_{n \rightarrow \infty} \mathbb{P}(A_n) \quad (2.6.2)$$

The continuity theorems can be applied to the increasing and decreasing sequences that we constructed earlier from an arbitrary sequence of events.

Suppose that (A_1, A_2, \dots) is a sequence of events.

1. $\mathbb{P}(\bigcup_{i=1}^{\infty} A_i) = \lim_{n \rightarrow \infty} \mathbb{P}(\bigcup_{i=1}^n A_i)$
2. $\mathbb{P}(\bigcap_{i=1}^{\infty} A_i) = \lim_{n \rightarrow \infty} \mathbb{P}(\bigcap_{i=1}^n A_i)$

Proof

These results follow immediately from the [continuity theorems](#).

Suppose that (A_1, A_2, \dots) is a sequence of events. Then

1. $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = \lim_{n \rightarrow \infty} \mathbb{P}(\bigcup_{i=n}^{\infty} A_i)$
2. $\mathbb{P}(\liminf_{n \rightarrow \infty} A_n) = \lim_{n \rightarrow \infty} \mathbb{P}(\bigcap_{i=n}^{\infty} A_i)$

Proof

These results follows directly from the [definitions](#), and the continuity theorems.

The next result shows that the countable additivity axiom for a probability measure is equivalent to *finite additivity* and the continuity property for increasing events.

Temporarily, suppose that \mathbb{P} is only finitely additive, but satisfies the [continuity property for increasing events](#). Then \mathbb{P} is countably additive.

Proof

Suppose that (A_1, A_2, \dots) is a sequence of pairwise disjoint events. Since we are assuming that \mathbb{P} is finitely additive we have

$$\mathbb{P}\left(\bigcup_{i=1}^n A_i\right) = \sum_{i=1}^n \mathbb{P}(A_i) \quad (2.6.3)$$

If we let $n \rightarrow \infty$, the left side converges to $\mathbb{P}(\bigcup_{i=1}^{\infty} A_i)$ by the continuity assumption and the result [above](#), while the right side converges to $\sum_{i=1}^{\infty} \mathbb{P}(A_i)$ by the definition of an infinite series.

There are a few mathematicians who reject the countable additivity axiom of probability measure in favor of the weaker finite additivity axiom. Whatever the philosophical arguments may be, life is certainly much harder without the continuity theorems.

The Borel-Cantelli Lemmas

The *Borel-Cantelli Lemmas*, named after Emil Borel and Francesco Cantelli, are very important tools in probability theory. The first lemma gives a condition that is sufficient to conclude that infinitely many events occur with probability 0.

First Borel-Cantelli Lemma. Suppose that (A_1, A_2, \dots) is a sequence of events. If $\sum_{n=1}^{\infty} \mathbb{P}(A_n) < \infty$ then $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = 0$.

Proof

From the result above on [limit superiors](#), we have $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = \lim_{n \rightarrow \infty} \mathbb{P}(\bigcup_{i=n}^{\infty} A_i)$. But from Boole's inequality, $\mathbb{P}(\bigcup_{i=n}^{\infty} A_i) \leq \sum_{i=n}^{\infty} \mathbb{P}(A_i)$. Since $\sum_{i=1}^{\infty} \mathbb{P}(A_i) < \infty$, we have $\sum_{i=n}^{\infty} \mathbb{P}(A_i) \rightarrow 0$ as $n \rightarrow \infty$.

The second lemma gives a condition that is sufficient to conclude that infinitely many *independent* events occur with probability 1.

Second Borel-Cantelli Lemma. Suppose that (A_1, A_2, \dots) is a sequence of independent events. If $\sum_{n=1}^{\infty} \mathbb{P}(A_n) = \infty$ then $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = 1$.

Proof

Note first that $1 - x \leq e^{-x}$ for every $x \in \mathbb{R}$, and hence $1 - \mathbb{P}(A_i) \leq \exp[-\mathbb{P}(A_i)]$ for each $i \in \mathbb{N}_+$. From the results above on [limit superiors](#) and [complements](#),

$$\mathbb{P}\left[\left(\limsup_{n \rightarrow \infty} A_n\right)^c\right] = \mathbb{P}\left(\liminf_{n \rightarrow \infty} A_n^c\right) = \lim_{n \rightarrow \infty} \mathbb{P}\left(\bigcap_{i=n}^{\infty} A_i^c\right) \quad (2.6.4)$$

But by independence and the inequality above,

$$\mathbb{P}\left(\bigcap_{i=n}^{\infty} A_i^c\right) = \prod_{i=n}^{\infty} \mathbb{P}(A_i^c) = \prod_{i=n}^{\infty} [1 - \mathbb{P}(A_i)] \leq \prod_{i=n}^{\infty} \exp[-\mathbb{P}(A_i)] = \exp\left(-\sum_{i=n}^{\infty} \mathbb{P}(A_i)\right) = 0 \quad (2.6.5)$$

For independent events, both Borel-Cantelli lemmas apply of course, and lead to a *zero-one law*.

If (A_1, A_2, \dots) is a sequence of independent events then $\limsup_{n \rightarrow \infty} A_n$ has probability 0 or 1:

1. If $\sum_{n=1}^{\infty} \mathbb{P}(A_n) < \infty$ then $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = 0$.
2. If $\sum_{n=1}^{\infty} \mathbb{P}(A_n) = \infty$ then $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = 1$.

This result is actually a special case of a more general zero-one law, known as the *Kolmogorov zero-one law*, and named for Andrei Kolmogorov. This law is studied in the more advanced section on measure. Also, we can use the zero-one law to derive a calculus theorem that relates infinite series and infinite products. This derivation is an example of the *probabilistic method*—the use of probability to obtain results, seemingly unrelated to probability, in other areas of mathematics.

Suppose that $p_i \in (0, 1)$ for each $i \in \mathbb{N}_+$. Then

$$\prod_{i=1}^{\infty} p_i > 0 \text{ if and only if } \sum_{i=1}^{\infty} (1 - p_i) < \infty \quad (2.6.6)$$

Proof

We can easily construct a probability space with a sequence of independent events (A_1, A_2, \dots) such that $\mathbb{P}(A_i) = 1 - p_i$ for each $i \in \mathbb{N}_+$. The result then follows from the proofs of the two Borel-Cantelli lemmas.

Our next result is a simple application of the second Borel-Cantelli lemma to independent replications of a basic experiment.

Suppose that A is an event in a basic random experiment with $\mathbb{P}(A) > 0$. In the compound experiment that consists of independent replications of the basic experiment, the event “ A occurs infinitely often” has probability 1.

Proof

Let p denote the probability of A in the basic experiment. In the compound experiment, we have a sequence of independent events (A_1, A_2, \dots) with $\mathbb{P}(A_n) = p$ for each $n \in \mathbb{N}_+$ (these are “independent copies” of A). But $\sum_{n=1}^{\infty} \mathbb{P}(A_n) = \infty$ since $p > 0$ so the result follows from the second Borel-Cantelli lemma.

Convergence of Random Variables

Our next discussion concerns two ways that a sequence of random variables defined for our experiment can “converge”. These are fundamentally important concepts, since some of the deepest results in probability theory are limit theorems involving random variables. The most important special case is when the random variables are real valued, but the proofs are essentially the same for variables with values in a metric space, so we will use the more general setting.

Thus, suppose that (S, d) is a metric space, and that \mathcal{S} is the corresponding Borel σ -algebra (that is, the σ -algebra generated by the topology), so that our measurable space is (S, \mathcal{S}) . Here is the most important special case:

For $n \in \mathbb{N}_+$, is the n -dimensional *Euclidean space* is (\mathbb{R}^n, d_n) where

$$d_n(\mathbf{x}, \mathbf{y}) = \sqrt{\sum_{i=1}^n (y_i - x_i)^2}, \quad \mathbf{x} = (x_1, x_2, \dots, x_n), \mathbf{y} = (y_1, y_2, \dots, y_n) \in \mathbb{R}^n \quad (2.6.7)$$

Euclidean spaces are named for Euclid, of course. As noted above, the one-dimensional case where $d(x, y) = |y - x|$ for $x, y \in \mathbb{R}$ is particularly important. Returning to the general metric space, recall that if (x_1, x_2, \dots) is a sequence in S and $x \in S$, then $x_n \rightarrow x$ as $n \rightarrow \infty$ means that $d(x_n, x) \rightarrow 0$ as $n \rightarrow \infty$ (in the usual calculus sense). For the rest of our discussion, we assume that (X_1, X_2, \dots) is a sequence of random variable with values in S and X is a random variable with values in S , all defined on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$.

We say that $X_n \rightarrow X$ as $n \rightarrow \infty$ *with probability 1* if the event that $X_n \rightarrow X$ as $n \rightarrow \infty$ has probability 1. That is,

$$\mathbb{P}\{\omega \in S : X_n(\omega) \rightarrow X(\omega) \text{ as } n \rightarrow \infty\} = 1 \quad (2.6.8)$$

Details

We need to make sure that the definition makes sense, in that the statement that X_n converges to X as $n \rightarrow \infty$ defines a valid event. Note that X_n does *not* converge to X as $n \rightarrow \infty$ if and only if for some $\epsilon > 0$, $d(X_n, X) > \epsilon$ for infinitely many $n \in \mathbb{N}_+$. Note that if this condition holds for a given $\epsilon > 0$ then it holds for all smaller $\epsilon > 0$. Moreover, there are arbitrarily small rational $\epsilon > 0$ so X_n does not converge to X as $n \rightarrow \infty$ if and only if for some rational $\epsilon > 0$, $d(X_n, X) > \epsilon$ for infinitely many $n \in \mathbb{N}_+$. Hence

$$\{X_n \rightarrow X \text{ as } n \rightarrow \infty\}^c = \bigcup_{\epsilon \in \mathbb{Q}_+} \limsup_{n \rightarrow \infty} \{d(X_n, X) > \epsilon\} \quad (2.6.9)$$

where \mathbb{Q}_+ is the set of positive rational numbers. A critical point to remember is that this set is countable. So, building a little at a time, note that $\{d(X_n, X) > \epsilon\}$ is an event for each $\epsilon \in \mathbb{Q}_+$ and $n \in \mathbb{N}_+$ since X_n and X are random variables. Next, the limit superior of a sequence of events is an event. Finally, a countable union of events is an event.

As good probabilists, we usually suppress references to the sample space and write the definition simply as $\mathbb{P}(X_n \rightarrow X \text{ as } n \rightarrow \infty) = 1$. The statement that an event has probability 1 is usually the strongest affirmative statement that we can make in probability theory. Thus, convergence with probability 1 is the strongest form of convergence. The phrases *almost surely* and *almost everywhere* are sometimes used instead of the phrase *with probability 1*.

Recall that metrics d and e on S are *equivalent* if they generate the same topology on S . Recall also that convergence of a sequence is a *topological property*. That is, if (x_1, x_2, \dots) is a sequence in S and $x \in S$, and if d, e are equivalent metrics on S , then $x_n \rightarrow x$ as $n \rightarrow \infty$ relative to d if and only if $x_n \rightarrow x$ as $n \rightarrow \infty$ relative to e . So for our random variables as defined above, it follows that $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1 relative to d if and only if $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1 relative to e .

The following statements are equivalent:

1. $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1.
2. $\mathbb{P}[d(X_n, X) > \epsilon \text{ for infinitely many } n \in \mathbb{N}_+] = 0$ for every rational $\epsilon > 0$.
3. $\mathbb{P}[d(X_n, X) > \epsilon \text{ for infinitely many } n \in \mathbb{N}_+] = 0$ for every $\epsilon > 0$.
4. $\mathbb{P}[d(X_k, X) > \epsilon \text{ for some } k \geq n] \rightarrow 0$ as $n \rightarrow \infty$ for every $\epsilon > 0$.

Proof

From the details in the [definition above](#), $\mathbb{P}(X_n \rightarrow X \text{ as } n \rightarrow \infty) = 1$ if and only if

$$\mathbb{P}\left(\bigcup_{\epsilon \in \mathbb{Q}_+} \{d(X_n, X) > \epsilon \text{ for infinitely many } n \in \mathbb{N}_+\}\right) = 0 \quad (2.6.10)$$

where again \mathbb{Q}_+ is the set of positive rational numbers. But by Boole's inequality, a countable union of events has probability 0 if and only if every event in the union has probability 0. Thus, (a) is equivalent to (b). Statement (b) is clearly equivalent to (c) since there are arbitrarily small positive rational numbers. Finally, (c) is equivalent to (d) by the continuity result in [above](#).

Our next result gives a fundamental criterion for convergence with probability 1:

If $\sum_{n=1}^{\infty} \mathbb{P}[d(X_n, X) > \epsilon] < \infty$ for every $\epsilon > 0$ then $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1.

Proof

By the [first Borel-Cantelli lemma](#), if $\sum_{n=1}^{\infty} \mathbb{P}[d(X_n, X) > \epsilon] < \infty$ then $\mathbb{P}[d(X_n, X) > \epsilon \text{ for infinitely many } n \in \mathbb{N}_+] = 0$. Hence the result follows from the previous theorem.

Here is our next mode of convergence.

We say that $X_n \rightarrow X$ as $n \rightarrow \infty$ *in probability* if

$$\mathbb{P}[d(X_n, X) > \epsilon] \rightarrow 0 \text{ as } n \rightarrow \infty \text{ for each } \epsilon > 0 \quad (2.6.11)$$

The phrase *in probability* sounds superficially like the phrase *with probability 1*. However, as we will soon see, convergence in probability is much weaker than convergence with probability 1. Indeed, convergence with probability 1 is often called *strong*

convergence, while convergence in probability is often called *weak convergence*.

If $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1 then $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability.

Proof

Let $\epsilon > 0$. Then $\mathbb{P}[d(X_n, X) > \epsilon] \leq \mathbb{P}[d(X_k, X) > \epsilon \text{ for some } k \geq n]$. But if $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1, then the expression on the right converges to 0 as $n \rightarrow \infty$ by part (d) of the result [above](#). Hence $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability.

The converse fails with a passion. A simple counterexample is given [below](#). However, there is a partial converse that is very useful.

If $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability, then there exists a subsequence $(n_1, n_2, n_3 \dots)$ of \mathbb{N}_+ such that $X_{n_k} \rightarrow X$ as $k \rightarrow \infty$ with probability 1.

Proof

Suppose that $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability. Then for each $k \in \mathbb{N}_+$ there exists $n_k \in \mathbb{N}_+$ such that $\mathbb{P}[d(X_{n_k}, X) > 1/k] < 1/k^2$. We can make the choices so that $n_k < n_{k+1}$ for each k . It follows that $\sum_{k=1}^{\infty} \mathbb{P}[d(X_{n_k}, X) > \epsilon] < \infty$ for every $\epsilon > 0$. By the result [above](#), $X_{n_k} \rightarrow X$ as $n \rightarrow \infty$ with probability 1.

Note that the proof works because $1/k \rightarrow 0$ as $k \rightarrow \infty$ and $\sum_{k=1}^{\infty} 1/k^2 < \infty$. Any two sequences with these properties would work just as well.

There are two other modes of convergence that we will discuss later:

- Convergence in distribution.
- Convergence in mean,

Examples and Applications

Coins

Suppose that we have an infinite sequence of coins labeled $1, 2, \dots$. Moreover, coin n has probability of heads $1/n^a$ for each $n \in \mathbb{N}_+$, where $a > 0$ is a parameter. We toss each coin in sequence one time. In terms of a , find the probability of the following events:

1. infinitely many heads occur
2. infinitely many tails occur

Answer

Let H_n be the event that toss n results in heads, and T_n the event that toss n results in tails.

1. $\mathbb{P}(\limsup_{n \rightarrow \infty} H_n) = 1$, $\mathbb{P}(\limsup_{n \rightarrow \infty} T_n) = 1$ if $a \in (0, 1]$
2. $\mathbb{P}(\limsup_{n \rightarrow \infty} H_n) = 0$, $\mathbb{P}(\limsup_{n \rightarrow \infty} T_n) = 1$ if $a \in (1, \infty)$

The following exercise gives a simple example of a sequence of random variables that converge in probability but not with probability 1. Naturally, we are assuming the standard metric on \mathbb{R} .

Suppose again that we have a sequence of coins labeled $1, 2, \dots$, and that coin n lands heads up with probability $\frac{1}{n}$ for each n . We toss the coins in order to produce a sequence (X_1, X_2, \dots) of independent indicator random variables with

$$\mathbb{P}(X_n = 1) = \frac{1}{n}, \quad \mathbb{P}(X_n = 0) = 1 - \frac{1}{n}; \quad n \in \mathbb{N}_+ \quad (2.6.12)$$

1. $\mathbb{P}(X_n = 0 \text{ for infinitely many } n) = 1$, so that infinitely many tails occur with probability 1.
2. $\mathbb{P}(X_n = 1 \text{ for infinitely many } n) = 1$, so that infinitely many heads occur with probability 1.
3. $\mathbb{P}(X_n \text{ does not converge as } n \rightarrow \infty) = 1$.
4. $X_n \rightarrow 0$ as $n \rightarrow \infty$ in probability.

Proof

1. This follows from the second Borel-Cantelli lemma, since $\sum_{n=1}^{\infty} \mathbb{P}(X_n = 0) = \infty$

2. This also follows from the second Borel-Cantelli lemma, since $\sum_{n=1}^{\infty} \mathbb{P}(X_n = 1) = \infty$.
3. This follows from parts (a) and (b). Recall that the intersection of two events with probability 1 still has probability 1.
4. Suppose $0 < \epsilon < 1$. Then $\mathbb{P}(|X_n - 0| > \epsilon) = \mathbb{P}(X_n = 1) = \frac{1}{n} \rightarrow 0$ as $n \rightarrow \infty$.

Discrete Spaces

Recall that a measurable space (S, \mathcal{S}) is *discrete* if S is countable and \mathcal{S} is the collection of all subsets of S (the power set of S). Moreover, \mathcal{S} is the Borel σ -algebra corresponding to the *discrete metric* d on S given by $d(x, x) = 0$ for $x \in S$ and $d(x, y) = 1$ for distinct $x, y \in S$. How do convergence with probability 1 and convergence in probability work for the discrete metric?

Suppose that (S, \mathcal{S}) is a discrete space. Suppose further that (X_1, X_2, \dots) is a sequence of random variables with values in S and X is a random variable with values in S , all defined on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Relative to the discrete metric d ,

1. $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1 if and only if $\mathbb{P}(X_n = X \text{ for all but finitely many } n \in \mathbb{N}_+) = 1$.
2. $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability if and only if $\mathbb{P}(X_n \neq X) \rightarrow 0$ as $n \rightarrow \infty$.

Proof

1. If (x_1, x_2, \dots) is a sequence of points in S and $x \in S$, then relative to metric d , $x_n \rightarrow x$ as $n \rightarrow \infty$ if and only if $x_n = x$ for all but finitely many $n \in \mathbb{N}_+$.
2. If $\epsilon \geq 1$ then $\mathbb{P}[d(X_n, X) > \epsilon] = 0$. If $\epsilon \in (0, 1)$ then $\mathbb{P}[d(X_n, X) > \epsilon] = \mathbb{P}(X_n \neq X)$.

Of course, it's important to realize that a discrete space can be the Borel space for metrics other than the discrete metric.

2.7: Measure Spaces

In this section we discuss positive measure spaces (which include probability spaces) from a more advanced point of view. The sections on Measure Theory and Special Set Structures in the chapter on Foundations are essential prerequisites. On the other hand, if you are not interested in the measure-theoretic aspects of probability, you can safely skip this section.

Positive Measure

Definitions

Suppose that S is a set, playing the role of a universal set for a mathematical theory. As we have noted before, S usually comes with a σ -algebra \mathcal{S} of admissible subsets of S , so that (S, \mathcal{S}) is a *measurable space*. In particular, this is the case for the model of a random experiment, where S is the set of outcomes and \mathcal{S} the σ -algebra of events, so that the measurable space (S, \mathcal{S}) is the *sample space* of the experiment. A probability measure is a special case of a more general object known as a positive measure.

A *positive measure* on (S, \mathcal{S}) is a function $\mu : \mathcal{S} \rightarrow [0, \infty]$ that satisfies the following axioms:

1. $\mu(\emptyset) = 0$
2. If $\{A_i : i \in I\}$ is a countable, pairwise disjoint collection of sets in \mathcal{S} then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{i \in I} \mu(A_i) \quad (2.7.1)$$

The triple (S, \mathcal{S}, μ) is a *measure space*.

Axiom (b) is called *countable additivity*, and is the essential property. The measure of a set that consists of a countable union of disjoint pieces is the sum of the measures of the pieces. Note also that since the terms in the sum are positive, there is no issue with the order of the terms in the sum, although of course, ∞ is a possible value.

Figure 2.7.1: A union of four disjoint sets

So perhaps the term *measurable space* for (S, \mathcal{S}) makes a little more sense now—a measurable space is one that can have a positive measure defined on it.

Suppose that (S, \mathcal{S}, μ) is a measure space.

1. If $\mu(S) < \infty$ then (S, \mathcal{S}, μ) is a *finite measure space*.
2. If $\mu(S) = 1$ then (S, \mathcal{S}, μ) is a *probability space*.

So probability measures are positive measures, but positive measures are important beyond the application to probability. The standard measures on the Euclidean spaces are all positive measures: the extension of *length* for measurable subsets of \mathbb{R} , the extension of *area* for measurable subsets of \mathbb{R}^2 , the extension of *volume* for measurable subsets of \mathbb{R}^3 , and the higher dimensional analogues. We will actually construct these measures in the next section on Existence and Uniqueness. In addition, counting measure $\#$ is a positive measure on the subsets of a set S . Even more general measures that can take positive and negative values are explored in the chapter on Distributions.

Properties

The following results give some simple properties of a positive measure space (S, \mathcal{S}, μ) . The proofs are essentially identical to the proofs of the corresponding properties of probability, except that the measure of a set may be infinite so we must be careful to avoid the dreaded indeterminate form $\infty - \infty$.

If $A, B \in \mathcal{S}$, then $\mu(B) = \mu(A \cap B) + \mu(B \setminus A)$.

Proof

Note that $B = (A \cap B) \cup (B \setminus A)$, and the sets in the union are disjoint.

If $A, B \in \mathcal{S}$ and $A \subseteq B$ then

1. $\mu(B) = \mu(A) + \mu(B \setminus A)$
2. $\mu(A) \leq \mu(B)$

Proof

Part (a) follows from the previous theorem, since $A \cap B = A$. Part (b) follows from part (a).

Thus μ is an *increasing function*, relative to the subset partial order \subseteq on \mathcal{S} and the ordinary order \leq on $[0, \infty]$. In particular, if μ is a finite measure, then $\mu(A) < \infty$ for every $A \in \mathcal{S}$. Note also that if $A, B \in \mathcal{S}$ and $\mu(B) < \infty$ then $\mu(B \setminus A) = \mu(B) - \mu(A \cap B)$. In the special case that $A \subseteq B$, this becomes $\mu(B \setminus A) = \mu(B) - \mu(A)$. In particular, these results holds for a finite measure and are just like the difference rules for probability. If μ is a finite measure, then $\mu(A^c) = \mu(S) - \mu(A)$. This is the analogue of the complement rule in probability, with but with $\mu(S)$ replacing 1.

The following result is the analogue of Boole's inequality for probability. For a general positive measure, the result is referred to as the *subadditive property*.

Suppose that $A_i \in \mathcal{S}$ for i in a countable index set I . Then

$$\mu\left(\bigcup_{i \in I} A_i\right) \leq \sum_{i \in I} \mu(A_i) \quad (2.7.2)$$

Proof

The proof is exactly like the one for Boole's inequality. Assume that $I = \mathbb{N}_+$. Let $B_1 = A_1$ and $B_i = A_i \setminus (A_1 \cup \dots \cup A_{i-1})$ for $i \in \{2, 3, \dots\}$. Then $\{B_i : i \in I\}$ is a disjoint collection of sets in \mathcal{S} with the same union as $\{A_i : i \in I\}$. Also $B_i \subseteq A_i$ for each i so $\mu(B_i) \leq \mu(A_i)$. Hence

$$\mu\left(\bigcup_{i \in I} A_i\right) = \mu\left(\bigcup_{i \in I} B_i\right) = \sum_{i \in I} \mu(B_i) \leq \sum_{i \in I} \mu(A_i) \quad (2.7.3)$$

For a union of sets with finite measure, the inclusion-exclusion formula holds, and the proof is just like the one for probability.

Suppose that $A_i \in \mathcal{S}$ for each $i \in I$ where $\#(I) = n$, and that $\mu(A_i) < \infty$ for $i \in I$. Then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{k=1}^n (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mu\left(\bigcap_{j \in J} A_j\right) \quad (2.7.4)$$

Proof

The proof is by induction on n . The proof for $n = 2$ is simple: $A_1 \cup A_2 = A_1 \cup (A_2 \setminus A_1)$. The union on the right is disjoint, so using additivity and the difference rule,

$$\mu(A_1 \cup A_2) = \mu(A_1) + \mu(A_2 \setminus A_1) = \mu(A_1) + \mu(A_2) - \mu(A_1 \cap A_2) \quad (2.7.5)$$

Suppose now that the inclusion-exclusion formula holds for a given $n \in \mathbb{N}_+$, and consider the case $n + 1$. Then

$$\bigcup_{i=1}^{n+1} A_i = \left(\bigcup_{i=1}^n A_i\right) \cup \left[A_{n+1} \setminus \left(\bigcup_{i=1}^n A_i\right)\right] \quad (2.7.6)$$

As before, the set in parentheses and the set in square brackets are disjoint. Thus using the additivity axiom, the difference rule, and the distributive rule we have

$$\mu\left(\bigcup_{i=1}^{n+1} A_i\right) = \mu\left(\bigcup_{i=1}^n A_i\right) + \mu(A_{n+1}) - \mu\left(\bigcup_{i=1}^n (A_{n+1} \cap A_i)\right) \quad (2.7.7)$$

By the induction hypothesis, the inclusion-exclusion formula holds for each union of n sets on the right. Applying the formula and simplifying gives the inclusion-exclusion formula for $n + 1$ sets.

The continuity theorem for increasing sets holds for a positive measure. The continuity theorem for decreasing events holds also, if the sets have finite measure. Again, the proofs are similar to the ones for a probability measure, except for considerations of infinite measure.

Suppose that (A_1, A_2, \dots) is a sequence of sets in \mathcal{S} .

1. If the sequence is increasing then $\mu(\bigcup_{i=1}^{\infty} A_i) = \lim_{n \rightarrow \infty} \mu(A_n)$.
2. If sequence is decreasing and $\mu(A_1) < \infty$ then $\mu(\bigcap_{i=1}^{\infty} A_i) = \lim_{n \rightarrow \infty} \mu(A_n)$.

Proof

1. Note that if $\mu(A_k) = \infty$ for some k then $\mu(A_n) = \infty$ for $n \geq k$ and $\mu(\bigcup_{i=1}^{\infty} A_i) = \infty$. Thus, suppose that $\mu(A_i) < \infty$ for each i . Let $B_1 = A_1$ and $B_i = A_i \setminus A_{i-1}$ for $i \in \{2, 3, \dots\}$. Then (B_1, B_2, \dots) is a disjoint sequence with the same union as (A_1, A_2, \dots) . Also, $\mu(B_1) = \mu(A_1)$ and by the [proper difference rule](#), $\mu(B_i) = \mu(A_i) - \mu(A_{i-1})$ for $i \in \{2, 3, \dots\}$. Hence

$$\mu\left(\bigcup_{i=1}^{\infty} A_i\right) = \mu\left(\bigcup_{i=1}^{\infty} B_i\right) = \sum_{i=1}^{\infty} \mu(B_i) = \lim_{n \rightarrow \infty} \sum_{i=1}^n \mu(B_i) \quad (2.7.8)$$

But $\sum_{i=1}^n \mu(B_i) = \mu(A_1) + \sum_{i=2}^n [\mu(A_i) - \mu(A_{i-1})] = \mu(A_n)$.

2. Note that $A_1 \setminus A_n$ is increasing in n . Hence using the continuity result for increasing sets,

$$\mu\left(\bigcap_{i=1}^{\infty} A_i\right) = \mu\left[A_1 \setminus \bigcup_{i=1}^{\infty} (A_1 \setminus A_i)\right] = \mu(A_1) - \mu\left[\bigcup_{i=1}^{\infty} (A_1 \setminus A_n)\right] \quad (2.7.9)$$

$$= \mu(A_1) - \lim_{n \rightarrow \infty} \mu(A_1 \setminus A_n) = \mu(A_1) - \lim_{n \rightarrow \infty} [\mu(A_1) - \mu(A_n)] = \lim_{n \rightarrow \infty} \mu(A_n) \quad (2.7.10)$$

Recall that if (A_1, A_2, \dots) is increasing, $\bigcup_{i=1}^{\infty} A_i$ is denoted $\lim_{n \rightarrow \infty} A_n$, and if (A_1, A_2, \dots) is decreasing, $\bigcap_{i=1}^{\infty} A_i$ is denoted $\lim_{n \rightarrow \infty} A_n$. In both cases, the continuity theorem has the form $\mu(\lim_{n \rightarrow \infty} A_n) = \lim_{n \rightarrow \infty} \mu(A_n)$. The continuity theorem for decreasing events fails without the additional assumption of finite measure. A simple counterexample is given [below](#).

The following corollary of the inclusion-exclusion law gives a condition for countable additivity that does not require that the sets be disjoint, but only that the intersections have measure 0. The result is used below in the [theorem on completion](#).

Suppose that $A_i \in \mathcal{S}$ for each i in a countable index set I and that $\mu(A_i) < \infty$ for $i \in I$ and $\mu(A_i \cap A_j) = 0$ for distinct $i, j \in I$. Then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{i \in I} \mu(A_i) \quad (2.7.11)$$

Proof

We will assume that $I = \mathbb{N}_+$. For $n \in \mathbb{N}_+$,

$$\mu\left(\bigcup_{i=1}^n A_i\right) = \sum_{i=1}^n \mu(A_i) \quad (2.7.12)$$

as an immediate consequence of the inclusion-exclusion law, under the assumption that $\mu(A_i \cap A_j) = 0$ for distinct $i, j \in \{1, 2, \dots, n\}$. Next $\bigcup_{i=1}^n A_i \uparrow \bigcup_{i=1}^{\infty} A_i$ as $n \rightarrow \infty$, and hence by the continuity theorem for increasing events, $\mu(\bigcup_{i=1}^n A_i) \rightarrow \mu(\bigcup_{i=1}^{\infty} A_i)$ as $n \rightarrow \infty$. On the other hand, $\sum_{i=1}^n \mu(A_i) \rightarrow \sum_{i=1}^{\infty} \mu(A_i)$ as $n \rightarrow \infty$ by the definition of an infinite series of nonnegative terms.

More Definitions

If a positive measure is not finite, then the following definition gives the next best thing.

The measure space (S, \mathcal{S}, μ) is σ -finite if there exists a countable collection $\{A_i : i \in I\} \subseteq \mathcal{S}$ with $\bigcup_{i \in I} A_i = S$ and $\mu(A_i) < \infty$ for each $i \in I$.

So of course, if μ is a finite measure on (S, \mathcal{S}) then μ is σ -finite, but not conversely in general. On the other hand, for $i \in I$, let $\mathcal{S}_i = \{A \in \mathcal{S} : A \subseteq A_i\}$. Then \mathcal{S}_i is a σ -algebra of subsets of A_i and μ restricted to \mathcal{S}_i is a finite measure. The point of this (and the reason for the definition) is that often nice properties of finite measures can be extended to σ -finite measures. In particular, σ -finite measure spaces play a crucial role in the construction of product measure spaces, and for the [completion](#) of a measure space considered below.

Suppose that (S, \mathcal{S}, μ) is a σ -finite measure space.

1. There exists an increasing sequence satisfying the σ -finite definition
2. There exists a disjoint sequence satisfying the σ -finite definition.

Proof

Without loss of generality, we can take \mathbb{N}_+ as the index set in the definition. So there exists $A_n \in \mathcal{S}$ for $n \in \mathbb{N}_+$ such that $\mu(A_n) < \infty$ for each $n \in \mathbb{N}_+$ and $S = \bigcup_{n=1}^{\infty} A_n$. The proof uses some of the same tricks that we have seen before.

1. Let $B_n = \bigcup_{i=1}^n A_i$. Then $B_n \in \mathcal{S}$ for $n \in \mathbb{N}_+$ and this sequence is increasing. Moreover, $\mu(B_n) \leq \sum_{i=1}^n \mu(A_i) < \infty$ for $n \in \mathbb{N}_+$ and $\bigcup_{n=1}^{\infty} B_n = \bigcup_{n=1}^{\infty} A_n = S$.
2. Let $C_1 = A_1$ and let $C_n = A_n \setminus \bigcup_{i=1}^{n-1} A_i$ for $n \in \{2, 3, \dots\}$. Then $C_n \in \mathcal{S}$ for each $n \in \mathbb{N}_+$ and this sequence is disjoint. Moreover, $C_n \subseteq A_n$ so $\mu(C_n) \leq \mu(A_n) < \infty$ and $\bigcup_{n=1}^{\infty} C_n = \bigcup_{n=1}^{\infty} A_n = S$.

Our next definition concerns sets where a measure is concentrated, in a certain sense.

Suppose that (S, \mathcal{S}, μ) is a measure space. An *atom* of the space is a set $A \in \mathcal{S}$ with the following properties:

1. $\mu(A) > 0$
2. If $B \in \mathcal{S}$ and $B \subseteq A$ then either $\mu(B) = \mu(A)$ or $\mu(B) = 0$.

A measure space that has no atoms is called *non-atomic* or *diffuse*.

In probability theory, we are often particularly interested in atoms that are singleton sets. Note that $\{x\} \in \mathcal{S}$ is an atom if and only if $\mu(\{x\}) > 0$, since the only subsets of $\{x\}$ are $\{x\}$ itself and \emptyset .

Constructions

There are several simple ways to construct new positive measures from existing ones. As usual, we start with a measurable space (S, \mathcal{S}) .

Suppose that (R, \mathcal{R}) is a measurable subspace of (S, \mathcal{S}) . If μ is a positive measure on (S, \mathcal{S}) then μ restricted to \mathcal{R} is a positive measure on (R, \mathcal{R}) . If μ is a finite measure on (S, \mathcal{S}) then μ is a finite measure on (R, \mathcal{R}) .

Proof

The assumption is that \mathcal{R} is a σ -algebra of subsets of R and $\mathcal{R} \subseteq \mathcal{S}$. In particular $R \in \mathcal{S}$. Since the additivity property of μ holds for a countable, disjoint collection of events in \mathcal{S} , it trivially holds for a countable, disjoint collection of events in \mathcal{R} . Finally, by the increasing property, $\mu(R) \leq \mu(S)$ so if $\mu(S) < \infty$ then $\mu(R) < \infty$.

However, if μ is σ -finite on (S, \mathcal{S}) , it is *not* necessarily true that μ is σ -finite on (R, \mathcal{R}) . A counterexample is given [below](#). The previous theorem would apply, in particular, when $R = S$ so that \mathcal{R} is a sub σ -algebra of \mathcal{S} . Next, a positive multiple of a positive measure gives another positive measure.

If μ is a positive measure on (S, \mathcal{S}) and $c \in (0, \infty)$, then $c\mu$ is also a positive measure on (S, \mathcal{S}) . If μ is finite (σ -finite) then $c\mu$ is finite (σ -finite) respectively.

Proof

Clearly $c\mu : \mathcal{S} \rightarrow [0, \infty]$. Also $(c\mu)(\emptyset) = c\mu(\emptyset) = 0$. Next if $\{A_i : i \in I\}$ is a countable, disjoint collection of events in \mathcal{S} then

$$(c\mu)\left(\bigcup_{i \in I} A_i\right) = c\mu\left(\bigcup_{i \in I} A_i\right) = c \sum_{i \in I} \mu(A_i) = \sum_{i \in I} c\mu(A_i) \quad (2.7.13)$$

Finally, since $\mu(A) < \infty$ if and only if $(c\mu)(A) < \infty$ for $A \in \mathcal{S}$, the finiteness and σ -finiteness properties are trivially preserved.

A nontrivial finite positive measure μ is practically just like a probability measure, and in fact can be re-scaled into a probability measure \mathbb{P} , as was done in the section on Probability Measures:

Suppose that μ is a positive measure on (S, \mathcal{S}) with $0 < \mu(S) < \infty$. Then \mathbb{P} defined by $\mathbb{P}(A) = \mu(A)/\mu(S)$ for $A \in \mathcal{S}$ is a probability measure on (S, \mathcal{S}) .

Proof

\mathbb{P} is a measure by the previous result, and trivially $\mathbb{P}(S) = 1$.

Sums of positive measures are also positive measures.

If μ_i is a positive measure on (S, \mathcal{S}) for each i in a countable index set I then $\mu = \sum_{i \in I} \mu_i$ is also a positive measure on (S, \mathcal{S}) .

1. If I is finite and μ_i is finite for each $i \in I$ then μ is finite.
2. If I is finite and μ_i is σ -finite for each $i \in I$ then μ is σ -finite.

Proof

Clearly $\mu : \mathcal{S} \rightarrow [0, \infty]$. First $\mu(\emptyset) = \sum_{i \in I} \mu_i(\emptyset) = 0$. Next if $\{A_j : j \in J\}$ is a countable, disjoint collection of events in \mathcal{S} then

$$\mu\left(\bigcup_{j \in J} A_j\right) = \sum_{i \in I} \mu_i\left(\bigcup_{j \in J} A_j\right) = \sum_{i \in I} \sum_{j \in J} \mu_i(A_j) = \sum_{j \in J} \sum_{i \in I} \mu_i(A_j) = \sum_{j \in J} \mu(A_j) \quad (2.7.14)$$

The interchange of sums is permissible since the terms are nonnegative. Suppose now that I is finite.

1. If μ_i is finite for each $i \in I$ then $\mu(S) = \sum_{i \in I} \mu_i(S) < \infty$ so μ is finite.
2. Suppose that μ_i is σ -finite for each $i \in I$. Then for each $i \in I$ there exists a collection $\mathcal{A}_i = \{A_{ij} : j \in \mathbb{N}\} \subseteq \mathcal{S}$ such that $\bigcup_{j=1}^{\infty} A_{ij} = S$ and $\mu_i(A_{ij}) < \infty$ for each $j \in \mathbb{N}$. For $j \in \mathbb{N}$, let $B_j = \bigcap_{i \in I} A_{ij}$. Then $B_j \in \mathcal{S}$ for each $j \in \mathbb{N}$ and

$$\bigcup_{j=1}^{\infty} B_j = \bigcup_{j=1}^{\infty} \bigcap_{i \in I} A_{ij} = \bigcap_{i \in I} \bigcup_{j=1}^{\infty} A_{ij} = \bigcap_{i \in I} S = S \quad (2.7.15)$$

Moreover,

$$\mu(B_j) = \sum_{i \in I} \mu_i(B_j) \leq \sum_{i \in I} \mu_i(A_{ij}) < \infty \quad (2.7.16)$$

so μ is σ -finite.

In the context of the last result, if I is countably infinite and μ_i is finite for each $i \in I$, then μ is not necessarily σ -finite. A counterexample is given below. In this case, μ is said to be *s-finite*, but we've had enough definitions, so we won't pursue this one. From [scaling](#) and [sum](#) properties, note that a positive linear combination of positive measures is a positive measure. The next method is sometimes referred to as a *change of variables*.

Suppose that (S, \mathcal{S}, μ) is a measure space. Suppose also that (T, \mathcal{T}) is another measurable space and that $f : S \rightarrow T$ is measurable. Then ν defined as follows is a positive measure on (T, \mathcal{T})

$$\nu(B) = \mu[f^{-1}(B)], \quad B \in \mathcal{T} \quad (2.7.17)$$

If μ is finite then ν is finite.

Proof

Clearly $\nu : \mathcal{T} \rightarrow [0, \infty]$. The proof is easy since inverse images preserve all set operations. First $f^{-1}(\emptyset) = \emptyset$ so $\nu(\emptyset) = 0$. Next, if $\{B_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{T} , then $\{f^{-1}(B_i) : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} , and $f^{-1}(\bigcup_{i \in I} B_i) = \bigcup_{i \in I} f^{-1}(B_i)$. Hence

$$\nu\left(\bigcup_{i \in I} B_i\right) = \mu\left[f^{-1}\left(\bigcup_{i \in I} B_i\right)\right] = \mu\left[\bigcup_{i \in I} f^{-1}(B_i)\right] = \sum_{i \in I} \mu[f^{-1}(B_i)] = \sum_{i \in I} \nu(B_i) \quad (2.7.18)$$

Finally, if μ is finite then $\nu(T) = \mu[f^{-1}(T)] = \mu(S) < \infty$ so ν is finite.

In the context of the last result, if μ is σ -finite on (S, \mathcal{S}) , it is not necessarily true that ν is σ -finite on (T, \mathcal{T}) , even if f is one-to-one. A counterexample is given below. The takeaway is that σ -finiteness of ν depends very much on the nature of the σ -algebra \mathcal{T} . Our next result shows that it's easy to explicitly construct a positive measure on a *countably generated σ -algebra*, that is, a σ -algebra generated by a countable partition. Such σ -algebras are important for counterexamples and to gain insight, and also because many σ -algebras that occur in applications can be constructed from them.

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ is a countable partition of S into nonempty sets, and that $\mathcal{S} = \sigma(\mathcal{A})$, the σ -algebra generated by the partition. For $i \in I$, define $\mu(A_i) \in [0, \infty]$ arbitrarily. For $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$, define

$$\mu(A) = \sum_{j \in J} \mu(A_j) \quad (2.7.19)$$

Then μ is a positive measure on (S, \mathcal{S}) .

1. The atoms of the measure are the sets of the form $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$ and where $\mu(A_j) > 0$ for one and only one $j \in J$.
2. If $\mu(A_i) < \infty$ for $i \in I$ and I is finite then μ is finite.
3. If $\mu(A_i) < \infty$ for $i \in I$ and I is countably infinite then μ is σ -finite.

Proof

Recall that every $A \in \mathcal{S}$ has a unique representation of the form $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$. In particular, $J = \emptyset$ in this representation gives $A = \emptyset$. The sum over an empty index set is 0, so $\mu(\emptyset) = 0$. Next suppose that $\{B_k : k \in K\}$ is a countable, disjoint collection of sets in \mathcal{S} . Then there exists a disjoint collection $\{J_k : k \in K\}$ of subsets of I such that $B_k = \bigcup_{j \in J_k} A_j$. Hence

$$\mu\left(\bigcup_{k \in K} B_k\right) = \mu\left(\bigcup_{k \in K} \bigcup_{j \in J_k} A_j\right) = \sum_{k \in K} \sum_{j \in J_k} \mu(A_j) = \sum_{k \in K} \mu(B_k) \quad (2.7.20)$$

The fact that the terms are all nonnegative means that we do not have to worry about the order of summation.

1. Again, every $A \in \mathcal{S}$ has the unique representation $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$. The subsets of A that are in \mathcal{S} are $\bigcup_{k \in K} A_k$ where $K \subseteq J$. Hence A is an atom if and only if $\mu(A_j) > 0$ for one and only one $j \in J$.
2. If I is finite and $\mu(A_i) < \infty$ then $\mu(S) = \sum_{i \in I} \mu(A_i) < \infty$, so μ is finite.
3. If I is countably infinite and $\mu(A_i) < \infty$ for $i \in I$ then \mathcal{A} satisfies the condition for μ to be σ -finite.

One of the most general ways to construct new measures from old ones is via the theory of integration with respect to a positive measure, which is explored in the chapter on Distributions. The construction of positive measures more or less “from scratch” is considered in the next section on Existence and Uniqueness. We close this discussion with a simple result that is useful for counterexamples.

Suppose that the measure space (S, \mathcal{S}, μ) has an atom $A \in \mathcal{S}$ with $\mu(A) = \infty$. Then the space is not σ -finite.

Proof

Let $\{A_i : i \in I\}$ be a countable disjoint collection of sets in \mathcal{S} that partitions S . Then $\{A \cap A_i : i \in I\}$ partitions A . Since $\mu(A) = \sum_{i \in I} \mu(A \cap A_i)$, we must have $\mu(A \cap A_i) > 0$ for some $i \in I$. Since A is an atom and $A \cap A_i \subseteq A$ it follows that $\mu(A \cap A_i) = \infty$. Hence also therefore $\mu(A_i) = \infty$.

Measure and Topology

Often the spaces that occur in probability and stochastic processes are topological spaces. Recall that a topological space (S, \mathcal{T}) consists of a set S and a topology \mathcal{T} on S (the collection of open sets). The topology as well as the measure theory plays an important role, so it's natural to want these two types of structures to be compatible. We have already seen the most important step in this direction: Recall that $\mathcal{S} = \sigma(\mathcal{T})$, the σ -algebra generated by the topology, is the *Borel σ -algebra* on S , named for Émile Borel.

Since the complement of an open set is a closed set, \mathcal{S} is also the σ -algebra generated by the collection of closed sets. Moreover, \mathcal{S} contains countable intersections of open sets (called G_δ sets) and countable unions of closed sets (called F_σ sets).

Suppose that (S, \mathcal{T}) is a topological space and let $\mathcal{S} = \sigma(\mathcal{T})$ be the Borel σ -algebra. A positive measure μ on (S, \mathcal{S}) is a *Borel measure* and then (S, \mathcal{S}, μ) is a *Borel measure space*.

The next definition concerns the subset on which a Borel measure is concentrated, in a certain sense.

Suppose that (S, \mathcal{S}, μ) is a Borel measure space. The *support* of μ is

$$\text{supp}(\mu) = \{x \in S : \mu(U) > 0 \text{ for every open neighborhood } U \text{ of } x\} \quad (2.7.21)$$

The set $\text{supp}(\mu)$ is closed.

Proof

Let $A = \text{supp}(\mu)^c$. For $x \in A^c$, there exists an open neighborhood V_x of x such that $\mu(V_x) = 0$. If $y \in V_x$, then V_x is also an open neighborhood of y , so $y \in A^c$. Hence $V_x \subseteq A^c$ for every $x \in A^c$ and so A^c is open.

The term *Borel measure* has different definitions in the literature. Often the topological space is required to be locally compact, Hausdorff, and with a countable base (*LCCB*). Then a Borel measure μ is required to have the additional condition that $\mu(C) < \infty$ if $C \subseteq S$ is compact. In this text, we use the term Borel measures in this more restricted sense.

Suppose that (S, \mathcal{S}, μ) is a Borel measure space corresponding to an LCCB topology. Then the space is σ -finite.

Proof

Since the topological space is locally compact and has a countable base, $S = \bigcup_{i \in I} C_i$ where $\{C_i : i \in I\}$ is a countable collection of compact sets. Since μ is a Borel measure, $\mu(C_i) < \infty$ and hence μ is σ -finite.

Here are a couple of other definitions that are important for Borel measures, again linking topology and measure in natural ways.

Suppose again that (S, \mathcal{S}, μ) is a Borel measure space.

1. μ is *inner regular* if $\mu(A) = \sup\{\mu(C) : C \text{ is compact and } C \subseteq A\}$ for $A \in \mathcal{S}$.
2. μ is *outer regular* if $\mu(A) = \inf\{\mu(U) : U \text{ is open and } A \subseteq U\}$ for $A \in \mathcal{S}$.
3. μ is *regular* if it is both inner regular and outer regular.

The measure spaces that occur in probability and stochastic processes are usually regular Borel spaces associated with LCCB topologies.

Null Sets and Equivalence

Sets of measure 0 in a measure space turn out to be very important precisely because we can often ignore the differences between mathematical objects on such sets. In this discussion, we assume that we have a fixed measure space (S, \mathcal{S}, μ) .

A set $A \in \mathcal{S}$ is *null* if $\mu(A) = 0$.

Consider a measurable “statement” with $x \in S$ as a free variable. (Technically, such a statement is a *predicate* on S .) If the statement is true for all $x \in S$ except for x in a null set, we say that the statement holds *almost everywhere* on S . This terminology is used often in measure theory and captures the importance of the definition.

Let $\mathcal{D} = \{A \in \mathcal{S} : \mu(A) = 0 \text{ or } \mu(A^c) = 0\}$, the collection of *null and co-null* sets. Then \mathcal{D} is a sub σ -algebra of \mathcal{S} .

Proof

Trivially $S \in \mathcal{D}$ since $S^c = \emptyset$ and $\mu(\emptyset) = 0$. Next if $A \in \mathcal{D}$ then $A^c \in \mathcal{D}$ by the symmetry of the definition. Finally, suppose that $A_i \in \mathcal{D}$ for $i \in I$ where I is a countable index set. If $\mu(A_i) = 0$ for every $i \in I$ then $\mu(\bigcup_{i \in I} A_i) \leq \sum_{i \in I} \mu(A_i) = 0$ by the [subadditive property](#). On the other hand, if $\mu(A_j^c) = 0$ for some $j \in J$ then $\mu[(\bigcup_{i \in I} A_i)^c] = \mu(\bigcap_{i \in I} A_i^c) \leq \mu(A_j^c) = 0$. In either case, $\bigcup_{i \in I} A_i \in \mathcal{D}$.

Of course μ restricted to \mathcal{S} is not very interesting since $\mu(A) = 0$ or $\mu(A) = \mu(S)$ for every $A \in \mathcal{S}$. Our next definition is a type of equivalence between sets in \mathcal{S} . To make this precise, recall first that the *symmetric difference* between subsets A and B of S is $A \triangle B = (A \setminus B) \cup (B \setminus A)$. This is the set that consists of points in one of the two sets, but not both, and corresponds to *exclusive or*.

Sets $A, B \in \mathcal{S}$ are *equivalent* if $\mu(A \triangle B) = 0$, and we denote this by $A \equiv B$.

Thus $A \equiv B$ if and only if $\mu(A \triangle B) = \mu(A \setminus B) + \mu(B \setminus A) = 0$ if and only if $\mu(A \setminus B) = \mu(B \setminus A) = 0$. In the predicate terminology mentioned above, the statement

$$x \in A \text{ if and only if } x \in B \quad (2.7.22)$$

is true for almost every $x \in S$. As the name suggests, the relation \equiv really is an equivalence relation on \mathcal{S} and hence \mathcal{S} is partitioned into disjoint classes of mutually equivalent sets. Two sets in the same equivalence class differ by a set of measure 0.

The relation \equiv is an equivalence relation on \mathcal{S} . That is, for $A, B, C \in \mathcal{S}$,

1. $A \equiv A$ (the *reflexive property*).
2. If $A \equiv B$ then $B \equiv A$ (the *symmetric property*).
3. If $A \equiv B$ and $B \equiv C$ then $A \equiv C$ (the *transitive property*).

Proof

1. The reflexive property is trivial since $A \triangle A = \emptyset$.
2. The symmetric property is also trivial since $A \triangle B = B \triangle A$.
3. For the transitive property, suppose that $A \equiv B$ and $B \equiv C$. Note that $A \setminus C \subseteq (A \setminus B) \cup (B \setminus C)$, and hence $\mathbb{P}(A \setminus C) = 0$. By a symmetric argument, $\mathbb{P}(C \setminus A) = 0$.

Equivalence is preserved under the standard set operations.

If $A, B \in \mathcal{S}$ and $A \equiv B$ then $A^c \equiv B^c$.

Proof

Note that $A^c \setminus B^c = B \setminus A$ and $B^c \setminus A^c = A \setminus B$, so $A^c \triangle B^c = A \triangle B$.

Suppose that $A_i, B_i \in \mathcal{S}$ and that $A_i \equiv B_i$ for i in a countable index set I . Then

1. $\bigcup_{i \in I} A_i \equiv \bigcup_{i \in I} B_i$
2. $\bigcap_{i \in I} A_i \equiv \bigcap_{i \in I} B_i$

Proof

1. Note that

$$\left(\bigcup_{i \in I} A_i \right) \triangle \left(\bigcup_{i \in I} B_i \right) \subseteq \bigcup_{i \in I} (A_i \triangle B_i) \quad (2.7.23)$$

To see this, note that if x is in the set on the left then either $x \in A_j$ for some $j \in I$ and $x \notin B_i$ for every $i \in I$, or $x \notin A_i$ for every $i \in I$ and $x \in B_j$ for some $j \in I$. In either case, $x \in A_j \triangle B_j$ for some $j \in I$.

2. Similarly

$$\left(\bigcap_{i \in I} A_i \right) \triangle \left(\bigcap_{i \in I} B_i \right) \subseteq \bigcup_{i \in I} (A_i \triangle B_i) \quad (2.7.24)$$

If x is in the set on the left then $x \in A_i$ for every $i \in I$ and $x \notin B_j$ for some $j \in I$, or $x \in B_i$ for every $i \in I$ and $x \notin A_j$ for some $j \in I$. In either case, $x \in A_j \triangle B_j$ for some $j \in I$.

In both parts, the proof is completed by noting that the common set on the right in the displayed equations is null:

$$\mu \left[\bigcup_{i \in I} (A_i \triangle B_i) \right] \leq \sum_{i \in I} \mu(A_i \triangle B_i) = 0 \quad (2.7.25)$$

Equivalent sets have the same measure.

If $A, B \in \mathcal{S}$ and $A \equiv B$ then $\mu(A) = \mu(B)$.

Proof

Note again that $A = (A \cap B) \cup (A \setminus B)$. If $A \equiv B$ then $\mu(A) = \mu(A \cap B)$. By a symmetric argument, $\mu(B) = \mu(A \cap B)$.

The converse trivially fails, and a counterexample is given [below](#). However, the collection of null sets and the collection of co-null sets do form equivalence classes.

Suppose that $A \in \mathcal{S}$.

1. If $\mu(A) = 0$ then $A \equiv B$ if and only if $\mu(B) = 0$.
2. If $\mu(A^c) = 0$ then $A \equiv B$ if and only if $\mu(B^c) = 0$.

Proof

1. Suppose that $\mu(A) = 0$ and $A \equiv B$. Then $\mu(B) = 0$ by the result [above](#). Conversely, note that $A \setminus B \subseteq A$ and $B \setminus A \subseteq B$ so if $\mu(A) = \mu(B) = 0$ then $\mu(A \triangle B) = 0$ so $A \equiv B$.
2. Part (b) follows from part (a) and the result above on [complements](#).

We can extend the notion of equivalence to measurable functions with a common range space. Thus suppose that (T, \mathcal{T}) is another measurable space. If $f, g: S \rightarrow T$ are measurable, then $(f, g): S \rightarrow T \times T$ is measurable with respect to the usual product σ -algebra $\mathcal{T} \otimes \mathcal{T}$. We assume that the diagonal set $D = \{(y, y) : y \in T\} \in \mathcal{T} \otimes \mathcal{T}$, which is almost always true in applications.

Measurable functions $f, g: S \rightarrow T$ are equivalent if $\mu\{x \in S : f(x) \neq g(x)\} = 0$. Again we write $f \equiv g$.

Details

Note that $\{x \in S : f(x) \neq g(x)\} = \{x \in S : (f(x), g(x)) \in D^c\} \in \mathcal{S}$ by our assumption, so the definition makes sense.

In the terminology discussed earlier, $f \equiv g$ means that $f(x) = g(x)$ almost everywhere on S . As with measurable sets, the relation \equiv really does define an equivalence relation on the collection of measurable functions from S to T . Thus, the collection of such functions is partitioned into disjoint classes of mutually equivalent variables.

The relation \equiv is an equivalence relation on the collection of measurable functions from S to T . That is, for measurable $f, g, h: S \rightarrow T$,

1. $f \equiv f$ (the reflexive property).
2. If $f \equiv g$ then $g \equiv f$ (the symmetric property).
3. If $f \equiv g$ and $g \equiv h$ then $f \equiv h$ (the transitive property).

Proof

Parts (a) and (b) are trivially. For (c) note that $f(x) = g(x)$ and $g(x) = h(x)$ implies $f(x) = h(x)$ for $x \in S$. Negating this statement gives $f(x) \neq h(x)$ implies $f(x) \neq g(x)$ or $g(x) \neq h(x)$. So

$$\{x \in S : f(x) \neq h(x)\} \subseteq \{x \in S : f(x) \neq g(x)\} \cup \{x \in S : g(x) \neq h(x)\} \quad (2.7.26)$$

Since $f \equiv g$ and $g \equiv h$, the two sets on the right have measure 0. Hence, so does the set on the left.

Suppose again that $f, g: S \rightarrow T$ are measurable and that $f \equiv g$. Then for every $B \in \mathcal{T}$, the sets $f^{-1}(B) \equiv g^{-1}(B)$.

Proof

Note that $f^{-1}(B) \triangle g^{-1}(B) \subseteq \{x \in S : f(x) \neq g(x)\}$.

Thus if $f, g: S \rightarrow T$ are measurable and $f \equiv g$, then by the previous result, $\nu_f = \nu_g$ where ν_f, ν_g are the measures on (T, \mathcal{T}) associated with f and g , as [above](#). Again, the converse fails with a passion.

It often happens that a definition for functions subsumes the corresponding definition for sets, by considering the indicator functions of the sets. So it is with equivalence. In the following result, we can take $T = \{0, 1\}$ with \mathcal{T} the collection of all subsets.

Suppose that $A, B \in \mathcal{S}$. Then $A \equiv B$ if and only if $\mathbf{1}_A \equiv \mathbf{1}_B$.

Proof

Note that $\{x \in S : 1_A(x) \neq 1_B(x)\} = A \triangle B$.

Equivalence is preserved under composition. For the next result, suppose that (U, \mathcal{U}) is yet another measurable space.

Suppose that $f, g : S \rightarrow T$ are measurable and that $h : T \rightarrow U$ is measurable. If $f \equiv g$ then $h \circ f \equiv h \circ g$.

Proof

Note that $\{x \in S : h[f(x)] \neq h[g(x)]\} \subseteq \{x \in S : f(x) \neq g(x)\}$.

Suppose again that (S, \mathcal{S}, μ) is a measure space. Let \mathcal{V} denote the collection of all measurable real-valued random functions from S into \mathbb{R} . (As usual, \mathbb{R} is given the Borel σ -algebra.) From our previous discussion of measure theory, we know that with the usual definitions of addition and scalar multiplication, $(\mathcal{V}, +, \cdot)$ is a vector space. However, in measure theory, we often do not want to distinguish between functions that are equivalent, so it's nice to know that the vector space structure is preserved when we *identify* equivalent functions. Formally, let $[f]$ denote the equivalence class generated by $f \in \mathcal{V}$, and let \mathcal{W} denote the collection of all such equivalence classes. In modular notation, \mathcal{W} is \mathcal{V}/\equiv . We define addition and scalar multiplication on \mathcal{W} by

$$[f] + [g] = [f + g], \quad c[f] = [cf]; \quad f, g \in \mathcal{V}, \quad c \in \mathbb{R} \quad (2.7.27)$$

$(\mathcal{W}, +, \cdot)$ is a vector space.

Proof

All that we have to show is that addition and scalar multiplication are well defined. That is, we must show that the definitions do not depend on the particular representative of the equivalence class. Then the other properties that define a vector space are inherited from $(\mathcal{V}, +, \cdot)$. Thus we must show that if $f_1 \equiv f_2$ and $g_1 \equiv g_2$, and if $c \in \mathbb{R}$, then $f_1 + g_1 \equiv f_2 + g_2$ and $cf_1 \equiv cf_2$. For the first problem, note that (f_1, g_1) and (f_2, g_2) are measurable functions from S to \mathbb{R}^2 . (\mathbb{R}^2 is given the product σ -algebra which also happens to be the Borel σ -algebra corresponding to the standard Euclidean topology). Moreover, $(f_1, g_1) \equiv (f_2, g_2)$ since

$$\{x \in S : (f_1(x), g_1(x)) \neq (f_2(x), g_2(x))\} = \{x \in S : f_1(x) \neq f_2(x)\} \cup \{x \in S : g_1(x) \neq g_2(x)\} \quad (2.7.28)$$

But the function $(a, b) \mapsto a + b$ from \mathbb{R}^2 into \mathbb{R} is measurable and hence from [composition property](#), it follows that $f_1 + g_1 \equiv f_2 + g_2$. The second problem is easier. The function $a \mapsto ca$ from \mathbb{R} into \mathbb{R} is measurable so again it follows from [composition property](#) that $cf_1 \equiv cf_2$.

Often we don't bother to use the special notation for the equivalence class associated with a function. Rather, it's understood that equivalent functions represent the same object. Spaces of functions in a measure space are studied further in the chapter on Distributions.

Completion

Suppose that (S, \mathcal{S}, μ) is a measure space and let $\mathcal{N} = \{A \in \mathcal{S} : \mu(A) = 0\}$ denote the collection of null sets of the space. If $A \in \mathcal{N}$ and $B \in \mathcal{S}$ is a subset of A , then we know that $\mu(B) = 0$ so $B \in \mathcal{N}$ also. However, in general there might be subsets of A that are not in \mathcal{S} . This leads naturally to the following definition.

The measure space (S, \mathcal{S}, μ) is *complete* if $A \in \mathcal{N}$ and $B \subseteq A$ imply $B \in \mathcal{S}$ (and hence $B \in \mathcal{N}$).

Our goal in this discussion is to show that if (S, \mathcal{S}, μ) is a σ -finite measure that is not complete, then it can be *completed*. That is μ can be extended to σ -algebra that includes all of the sets in \mathcal{S} and all subsets of null sets. The first step is to extend the equivalence relation defined in our previous discussion to $\mathcal{P}(S)$.

For $A, B \subseteq S$, define $A \equiv B$ if and only if there exists $N \in \mathcal{N}$ such that $A \triangle B \subseteq N$. The relation \equiv is an equivalence relation on $\mathcal{P}(S)$: For $A, B, C \subseteq S$,

1. $A \equiv A$ (the *reflexive property*).
2. If $A \equiv B$ then $B \equiv A$ (the *symmetric property*).
3. If $A \equiv B$ and $B \equiv C$ then $A \equiv C$ (the *transitive property*).

Proof

1. Note that $A \triangle A = \emptyset$ and $\emptyset \in \mathcal{N}$.
2. Suppose that $A \triangle B \subseteq N$ where $N \in \mathcal{N}$. Then $B \triangle A = A \triangle B \subseteq N$.
3. Suppose that $A \triangle B \subseteq N_1$ and $B \triangle C \subseteq N_2$ where $N_1, N_2 \in \mathcal{N}$. Then $A \triangle C \subseteq (A \triangle B) \cup (B \triangle C) \subseteq N_1 \cup N_2$, and $N_1 \cup N_2 \in \mathcal{N}$.

So the equivalence relation \equiv partitions $\mathcal{P}(S)$ into mutually disjoint equivalence classes. Two sets in an equivalence class differ by a subset of a null set. In particular, $A \equiv \emptyset$ if and only if $A \subseteq N$ for some $N \in \mathcal{N}$. The extended relation \equiv is preserved under the set operations, just as before. Our next step is to enlarge the σ -algebra \mathcal{S} by adding any set that is equivalent to a set in \mathcal{S} .

Let $\mathcal{S}_0 = \{A \subseteq S : A \equiv B \text{ for some } B \in \mathcal{S}\}$. Then \mathcal{S}_0 is a σ -algebra of subsets of S , and in fact is the σ -algebra generated by $\mathcal{S} \cup \{A \subseteq S : A \equiv \emptyset\}$.

Proof

Note that if $A \in \mathcal{S}$ then $A \equiv A$ so $A \in \mathcal{S}_0$. In particular, $S \in \mathcal{S}_0$. Also, $\emptyset \in \mathcal{S}$ so if $A \equiv \emptyset$ then $A \in \mathcal{S}_0$. Suppose that $A \in \mathcal{S}_0$ so that $A \equiv B$ for some $B \in \mathcal{S}$. Then $B^c \in \mathcal{S}$ and $A^c \equiv B^c$ so $A^c \in \mathcal{S}_0$. Next suppose that $A_i \in \mathcal{S}_0$ for i in a countable index set I . Then for each $i \in I$ there exists $B_i \in \mathcal{S}$ such that $A_i \equiv B_i$. But then $\bigcup_{i \in I} B_i \in \mathcal{S}$ and $\bigcup_{i \in I} A_i \equiv \bigcup_{i \in I} B_i$, so $\bigcup_{i \in I} A_i \in \mathcal{S}_0$. Therefore \mathcal{S}_0 is a σ -algebra of subsets of S . Finally, suppose that \mathcal{T} is a σ -algebra of subsets of S and that $\mathcal{S} \cup \{A \subseteq S : A \equiv \emptyset\} \subseteq \mathcal{T}$. We need to show that $\mathcal{S}_0 \subseteq \mathcal{T}$. Thus, suppose that $A \in \mathcal{S}_0$. Then there exists $B \in \mathcal{S}$ such that $A \equiv B$. But $B \in \mathcal{T}$ and $A \triangle B \in \mathcal{T}$ so $A \cap B = B \setminus (A \triangle B) \in \mathcal{T}$. Also $A \setminus B \in \mathcal{T}$, so $A = (A \cap B) \cup (A \setminus B) \in \mathcal{T}$.

Our last step is to extend μ to a positive measure on the enlarged σ -algebra \mathcal{S}_0 .

Suppose that $A \in \mathcal{S}_0$ so that $A \equiv B$ for some $B \in \mathcal{S}$. Define $\mu_0(A) = \mu(B)$. Then

1. μ_0 is well defined.
2. $\mu_0(A) = \mu(A)$ for $A \in \mathcal{S}$.
3. μ_0 is a positive measure on \mathcal{S}_0 .

The measure space $(S, \mathcal{S}_0, \mu_0)$ is complete and is known as the *completion* of (S, \mathcal{S}, μ) .

Proof

1. Suppose that $A \in \mathcal{S}_0$ and that $A \equiv B_1$ and $A \equiv B_2$ where $B_1, B_2 \in \mathcal{S}$. Then $B_1 \equiv B_2$ so by the result [above](#) $\mu(B_1) = \mu(B_2)$. Thus, μ_0 is well-defined.
2. Next, if $A \in \mathcal{S}$ then of course $A \equiv A$ so $\mu_0(A) = \mu(A)$.
3. Trivially $\mu_0(A) \geq 0$ for $A \in \mathcal{S}_0$. Thus we just need to show the countable additivity property. To understand the proof you need to keep several facts in mind: the functions μ and μ_0 agree on \mathcal{S} (property (b)); equivalence is preserved under set operations; equivalent sets have the same value under μ_0 (property (a)). Since the measure space (S, \mathcal{S}, μ) is σ -finite, there exists a countable disjoint collection $\{C_i : i \in I\}$ of sets in \mathcal{S} such that $S = \bigcup_{i \in I} C_i$ and $\mu(C_i) < \infty$ for each $i \in I$. Suppose first that $A \in \mathcal{S}_0$, so that there exists $B \in \mathcal{S}$ with $A \equiv B$. Then

$$\mu_0(A) = \mu_0\left[\bigcup_{i \in I} (A \cap C_i)\right] = \mu\left[\bigcup_{i \in I} (B \cap C_i)\right] = \sum_{i \in I} \mu(B \cap C_i) = \sum_{i \in I} \mu_0(A \cap C_i) \quad (2.7.29)$$

Suppose next that (A_1, A_2, \dots) is a sequence of pairwise disjoint sets in \mathcal{S}_0 so that there exists a sequence (B_1, B_2, \dots) of sets in \mathcal{S} such that $A_i \equiv B_i$ for each $i \in \mathbb{N}_+$. For fixed $i \in I$,

$$\mu_0\left[\bigcup_{n=1}^{\infty} (A_n \cap C_i)\right] = \mu_0\left[\bigcup_{n=1}^{\infty} (B_n \cap C_i)\right] = \mu\left[\bigcup_{n=1}^{\infty} (B_n \cap C_i)\right] = \sum_{n=1}^{\infty} \mu(B_n \cap C_i) = \sum_{n=1}^{\infty} \mu_0(A_n \cap C_i) \quad (2.7.30)$$

The next-to-the-last equality use the inclusion-exclusion law, since we don't know (and it's probably not true) that the sequence (B_1, B_2, \dots) is disjoint. The use of inclusion-exclusion is why we need (S, \mathcal{S}, μ) to be σ -finite. Finally, using the previous displayed equations,

$$\begin{aligned}\mu_0\left(\bigcup_{n=1}^{\infty} A_n\right) &= \sum_{i \in I} \mu_0\left[\left(\bigcup_{n=1}^{\infty} A_n\right) \cap C_i\right] = \sum_{i \in I} \mu_0\left(\bigcup_{n=1}^{\infty} A_n \cap C_i\right) \\ &= \sum_{i \in I} \sum_{n=1}^{\infty} \mu_0(A_n \cap C_i) = \sum_{n=1}^{\infty} \sum_{i \in I} \mu_0(A_n \cap C_i) = \sum_{n=1}^{\infty} \mu_0(A_n)\end{aligned}$$

Examples and Exercises

As always, be sure to try the computational exercises and proofs yourself before reading the answers and proofs in the text. Recall that a *discrete measure space* consists of a countable set, with the σ -algebra of all subsets, and with counting measure $\#$.

Counterexamples

The continuity theorem for decreasing events can fail if the events do not have finite measure.

Consider \mathbb{Z} with counting measure $\#$ on the σ -algebra of all subsets. Let $A_n = \{z \in \mathbb{Z} : z \leq -n\}$ for $n \in \mathbb{N}_+$. The continuity theorem fails for (A_1, A_2, \dots) .

Proof

The sequence is decreasing and $\#(A_n) = \infty$ for each n , but $\#(\bigcap_{i=1}^{\infty} A_i) = \#(\emptyset) = 0$.

Equal measure certainly does not imply equivalent sets.

Suppose that (S, \mathcal{S}, μ) is a measure space with the property that there exist disjoint sets $A, B \in \mathcal{S}$ such that $\mu(A) = \mu(B) > 0$. Then A and B are not equivalent.

Proof

Note that $A \triangle B = A \cup B$ and $\mu(A \cup B) > 0$.

For a concrete example, we could take $S = \{0, 1\}$ with counting measure $\#$ on σ -algebra of all subsets, and $A = \{0\}$, $B = \{1\}$.

The σ -finite property is not necessarily inherited by a sub-measure space. To set the stage for the counterexample, let \mathcal{B} denote the Borel σ -algebra of \mathbb{R} , that is, the σ -algebra generated by the standard Euclidean topology. There exists a positive measure λ on $(\mathbb{R}, \mathcal{B})$ that generalizes length. The measure λ , known as *Lebesgue measure*, is constructed in the section on Existence. Next let \mathcal{C} denote the σ -algebra of *countable and co-countable* sets:

$$\mathcal{C} = \{A \subseteq \mathbb{R} : A \text{ is countable or } A^c \text{ is countable}\} \quad (2.7.31)$$

That \mathcal{C} is a σ -algebra was shown in the section on measure theory in the chapter on foundations.

$(\mathbb{R}, \mathcal{C})$ is a subspace of $(\mathbb{R}, \mathcal{B})$. Moreover, $(\mathbb{R}, \mathcal{B}, \lambda)$ is σ -finite but $(\mathbb{R}, \mathcal{C}, \lambda)$ is not.

Proof

If $x \in \mathbb{R}$, then the singleton $\{x\}$ is closed and hence is in \mathcal{B} . A countable set is a countable union of singletons, so if A is countable then $A \in \mathcal{B}$. It follows that $\mathcal{C} \subset \mathcal{B}$. Next, let I_n denote the interval $[n, n+1)$ for $n \in \mathbb{Z}$. Then $\lambda(I_n) = 1$ for $n \in \mathbb{Z}$ and $\mathbb{R} = \bigcup_{n \in \mathbb{Z}} I_n$, so $(\mathbb{R}, \mathcal{B}, \lambda)$ is σ -finite. On the other hand, $\lambda\{x\} = 0$ for $x \in \mathbb{R}$ (since the set is an interval of length 0). Therefore $\lambda(A) = 0$ if A is countable and $\lambda(A) = \infty$ if A^c is countable. It follows that \mathbb{R} cannot be written as a countable union of sets in \mathcal{C} , each with finite measure.

A sum of finite measures may not be σ -finite.

Let S be a nonempty, finite set with the σ -algebra \mathcal{S} of all subsets. Let $\mu_n = \#$ be counting measure on (S, \mathcal{S}) for $n \in \mathbb{N}_+$. Then μ_n is a finite measure for each $n \in \mathbb{N}_+$, but $\mu = \sum_{n \in \mathbb{N}_+} \mu_n$ is not σ -finite.

Proof

Note that μ is the trivial measure on (S, \mathcal{S}) given by $\mu(A) = \infty$ if $A \neq \emptyset$ (and of course $\mu(\emptyset) = 0$).

Basic Properties

In the following problems, μ is a positive measure on the measurable space (S, \mathcal{S}) .

Suppose that $\mu(S) = 20$ and that $A, B \in \mathcal{S}$ with $\mu(A) = 5$, $\mu(B) = 6$, $\mu(A \cap B) = 2$. Find the measure of each of the following sets:

1. $A \setminus B$
2. $A \cup B$
3. $A^c \cup B^c$
4. $A^c \cap B^c$
5. $A \cup B^c$

Answer

1. 3
2. 9
3. 18
4. 11
5. 16

Suppose that $\mu(S) = \infty$ and that $A, B \in \mathcal{S}$ with $\mu(A \setminus B) = 2$, $\mu(B \setminus A) = 3$, and $\mu(A \cap B) = 4$. Find the measure of each of the following sets:

1. A
2. B
3. $A \cup B$
4. $A^c \cap B^c$
5. $A^c \cup B^c$

Answer

1. 6
2. 7
3. 9
4. ∞
5. ∞

Suppose that $\mu(S) = 10$ and that $A, B \in \mathcal{S}$ with $\mu(A) = 3$, $\mu(A \cup B) = 7$, and $\mu(A \cap B) = 2$. Find the measure of each of the following events:

1. B
2. $A \setminus B$
3. $B \setminus A$
4. $A^c \cup B^c$
5. $A^c \cap B^c$

Answer

1. 6
2. 1
3. 4
4. 8
5. 3

Suppose that $A, B, C \in \mathcal{S}$ with $\mu(A) = 10$, $\mu(B) = 12$, $\mu(C) = 15$, $\mu(A \cap B) = 3$, $\mu(A \cap C) = 4$, $\mu(B \cap C) = 5$, and $\mu(A \cap B \cap C) = 1$. Find the probabilities of the various unions:

1. $A \cup B$
2. $A \cup C$
3. $B \cup C$

4. $A \cup B \cup C$

Answer

1. 21
2. 23
3. 22
4. 28

2.8: Existence and Uniqueness

Suppose that S is a set and \mathcal{S} a σ -algebra of subsets of S , so that (S, \mathcal{S}) is a measurable space. In many cases, it is impossible to define a positive measure μ on \mathcal{S} explicitly, by giving a “formula” for computing $\mu(A)$ for each $A \in \mathcal{S}$. Rather, we often know how the measure μ should work on some class of sets \mathcal{B} that generates \mathcal{S} . We would then like to know that μ can be *extended* to a positive measure on \mathcal{S} , and that this extension is *unique*. The purpose of this section is to discuss the basic results on this topic. To understand this section you will need to review the sections on Measure Theory and Special Set Structures in the chapter on Foundations, and the section on Measure Spaces in this chapter. If you are not interested in questions of existence and uniqueness of positive measures, you can safely skip this section.

Basic Theory

Positive Measures on Algebras

Suppose first that \mathcal{A} is an algebra of subsets of S . Recall that this means that \mathcal{A} is a collection of subsets that contains S and is closed under complements and finite unions (and hence also finite intersections). Here is our first definition:

A *positive measure* on \mathcal{A} is a function $\mu : \mathcal{A} \rightarrow [0, \infty]$ that satisfies the following properties:

1. $\mu(\emptyset) = 0$
2. If $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{A} and if $\bigcup_{i \in I} A_i \in \mathcal{A}$ then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{i \in I} \mu(A_i) \quad (2.8.1)$$

Clearly the definition of a positive measure on an algebra is very similar to the definition for a σ -algebra. If the collection of sets in (b) is finite, then $\bigcup_{i \in I} A_i$ must be in the algebra \mathcal{A} . Thus, μ is finitely additive. If the collection is countably infinite, then there is no guarantee that the union is in \mathcal{A} . If it is however, then μ must be additive over this collection. Given the similarity, it is not surprising that μ shares many of the basic properties of a positive measure on a σ -algebra, with proofs that are almost identical.

If $A, B \in \mathcal{A}$, then $\mu(B) = \mu(A \cap B) + \mu(B \setminus A)$.

Proof

Note that $B = (A \cap B) \cup (B \setminus A)$, and the sets in the union are in the algebra \mathcal{A} and are disjoint.

If $A, B \in \mathcal{A}$ and $A \subseteq B$ then

1. $\mu(B) = \mu(A) + \mu(B \setminus A)$
2. $\mu(A) \leq \mu(B)$

Proof

Part (a) follows from the previous theorem, since $A \cap B = A$. Part (b) follows from part (a).

Thus μ is increasing, relative to the subset partial order \subseteq on \mathcal{A} and the ordinary order \leq on $[0, \infty]$. Note also that if $A, B \in \mathcal{A}$ and $\mu(B) < \infty$ then $\mu(B \setminus A) = \mu(B) - \mu(A \cap B)$. In the special case that $A \subseteq B$, this becomes $\mu(B \setminus A) = \mu(B) - \mu(A)$. If $\mu(S) < \infty$ then $\mu(A^c) = \mu(S) - \mu(A)$. These are the familiar *difference* and *complement* rules.

The following result is the *subadditive property* for a positive measure μ on an algebra \mathcal{A} .

Suppose that $\{A_i : i \in I\}$ is a countable collection of sets in \mathcal{A} and that $\bigcup_{i \in I} A_i \in \mathcal{A}$. Then

$$\mu\left(\bigcup_{i \in I} A_i\right) \leq \sum_{i \in I} \mu(A_i) \quad (2.8.2)$$

Proof

The proof is just like before. Assume that $I = \mathbb{N}_+$. Let $B_1 = A_1$ and $B_i = A_i \setminus (A_1 \cup \dots \cup A_{i-1})$ for $i \in \{2, 3, \dots\}$. Then $\{B_i : i \in I\}$ is a disjoint collection of sets in \mathcal{A} with the same union as $\{A_i : i \in I\}$. Also $B_i \subseteq A_i$ for each i so $\mu(B_i) \leq \mu(A_i)$. Hence if the union is in \mathcal{A} then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \mu\left(\bigcup_{i \in I} B_i\right) = \sum_{i \in I} \mu(B_i) \leq \sum_{i \in I} \mu(A_i) \quad (2.8.3)$$

For a finite union of sets with finite measure, the inclusion-exclusion formula holds, and the proof is just like the one for a probability measure.

Suppose that $\{A_i : i \in I\}$ is a finite collection of sets in \mathcal{A} where $\#(I) = n \in \mathbb{N}_+$, and that $\mu(A_i) < \infty$ for $i \in I$. Then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{k=1}^n (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mu\left(\bigcap_{j \in J} A_j\right) \quad (2.8.4)$$

The continuity theorems hold for a positive measure μ on an algebra \mathcal{A} , just as for a positive measure on a σ -algebra, assuming that the appropriate union and intersection are in the algebra. The proofs are just as before.

Suppose that (A_1, A_2, \dots) is a sequence of sets in \mathcal{A} .

1. If the sequence is increasing, so that $A_n \subseteq A_{n+1}$ for each $n \in \mathbb{N}_+$, and $\bigcup_{i=1}^{\infty} A_i \in \mathcal{A}$, then $\mu\left(\bigcup_{i=1}^{\infty} A_i\right) = \lim_{n \rightarrow \infty} \mu(A_n)$.
2. If the sequence is decreasing, so that $A_{n+1} \subseteq A_n$ for each $n \in \mathbb{N}_+$, and $\mu(A_1) < \infty$ and $\bigcap_{i=1}^{\infty} A_i \in \mathcal{A}$, then $\mu\left(\bigcap_{i=1}^{\infty} A_i\right) = \lim_{n \rightarrow \infty} \mu(A_n)$.

Proof

1. Note that if $\mu(A_k) = \infty$ for some k then $\mu(A_n) = \infty$ for $n \geq k$ and $\mu\left(\bigcup_{i=1}^{\infty} A_i\right) = \infty$ if this union is in \mathcal{A} . Thus, suppose that $\mu(A_i) < \infty$ for each i . Let $B_1 = A_1$ and $B_i = A_i \setminus A_{i-1}$ for $i \in \{2, 3, \dots\}$. Then (B_1, B_2, \dots) is a disjoint sequence in \mathcal{A} with the same union as (A_1, A_2, \dots) . Also, $\mu(B_1) = \mu(A_1)$ and $\mu(B_i) = \mu(A_i) - \mu(A_{i-1})$ for $i \in \{2, 3, \dots\}$. Hence if the union is in \mathcal{A} ,

$$\mu\left(\bigcup_{i=1}^{\infty} A_i\right) = \mu\left(\bigcup_{i=1}^{\infty} B_i\right) = \sum_{i=1}^{\infty} \mu(B_i) = \lim_{n \rightarrow \infty} \sum_{i=1}^n \mu(B_i) \quad (2.8.5)$$

But $\sum_{i=1}^n \mu(B_i) = \mu(A_1) + \sum_{i=2}^n [\mu(A_i) - \mu(A_{i-1})] = \mu(A_n)$.

2. Note that $A_1 \setminus A_n \in \mathcal{A}$ and this sequence is increasing. Moreover, $\bigcup_{n=1}^{\infty} (A_1 \setminus A_n) = \left(\bigcap_{n=1}^{\infty} A_n\right)^c \cap A_1$. Hence if $\bigcap_{n=1}^{\infty} A_n \in \mathcal{A}$ then $\bigcup_{n=1}^{\infty} (A_1 \setminus A_n) \in \mathcal{A}$. Thus using the continuity result for increasing sets,

$$\mu\left(\bigcap_{i=1}^{\infty} A_i\right) = \mu\left[A_1 \setminus \bigcup_{i=1}^{\infty} (A_1 \setminus A_i)\right] = \mu(A_1) - \mu\left[\bigcup_{i=1}^{\infty} (A_1 \setminus A_n)\right] \quad (2.8.6)$$

$$= \mu(A_1) - \lim_{n \rightarrow \infty} \mu(A_1 \setminus A_n) = \mu(A_1) - \lim_{n \rightarrow \infty} [\mu(A_1) - \mu(A_n)] = \lim_{n \rightarrow \infty} \mu(A_n) \quad (2.8.7)$$

Recall that if the sequence (A_1, A_2, \dots) is increasing, then we define $\lim_{n \rightarrow \infty} A_n = \bigcup_{n=1}^{\infty} A_n$, and if the sequence is decreasing then we define $\lim_{n \rightarrow \infty} A_n = \bigcap_{n=1}^{\infty} A_n$. Thus the conclusion of both parts of the continuity theorem is

$$\mathbb{P}\left(\lim_{n \rightarrow \infty} A_n\right) = \lim_{n \rightarrow \infty} \mathbb{P}(A_n) \quad (2.8.8)$$

Finite additivity and continuity for increasing events imply countable additivity:

If $\mu : \mathcal{A} \rightarrow [0, \infty]$ satisfies the properties below then μ is a positive measure on \mathcal{A} .

1. $\mu(\emptyset) = 0$
2. $\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{i \in I} \mu(A_i)$ if $\{A_i : i \in I\}$ is a finite disjoint collection of sets in \mathcal{A}
3. $\mu\left(\bigcup_{i=1}^{\infty} A_i\right) = \lim_{n \rightarrow \infty} \mu(A_n)$ if (A_1, A_2, \dots) is an increasing sequence of events in \mathcal{A} and $\bigcup_{i=1}^{\infty} A_i \in \mathcal{A}$.

Proof

All that is left to prove is additivity over a countably infinite collection of sets in \mathcal{A} when the union is also in \mathcal{A} . Thus suppose that $\{A_n : n \in \mathbb{N}\}$ is a disjoint collection of sets in \mathcal{A} with $\bigcup_{n=1}^{\infty} A_n \in \mathcal{A}$. Let $B_n = \bigcup_{i=1}^n A_i$ for $n \in \mathbb{N}_+$. Then $B_n \in \mathcal{A}$ and $\bigcup_{n=1}^{\infty} B_n = \bigcup_{n=1}^{\infty} A_n$. Hence using the finite additivity and the continuity property we have

$$\mathbb{P}\left(\bigcup_{n=1}^{\infty} A_n\right) = \mathbb{P}\left(\bigcup_{n=1}^{\infty} B_n\right) = \lim_{n \rightarrow \infty} \mathbb{P}(B_n) = \lim_{n \rightarrow \infty} \sum_{i=1}^n \mathbb{P}(A_i) = \sum_{i=1}^{\infty} \mathbb{P}(A_i) \quad (2.8.9)$$

Many of the basic theorems in measure theory require that the measure not be too far removed from being finite. This leads to the following definition, which is just like the one for a positive measure on a σ -algebra.

A measure μ on an algebra \mathcal{A} of subsets of S is σ -finite if there exists a sequence of sets (A_1, A_2, \dots) in \mathcal{A} such that $\bigcup_{n=1}^{\infty} A_n = S$ and $\mu(A_n) < \infty$ for each $n \in \mathbb{N}_+$. The sequence is called a σ -finite sequence for μ .

Suppose that μ is a σ -finite measure on an algebra \mathcal{A} of subsets of S .

1. There exists an increasing σ -finite sequence.
2. There exists a disjoint σ -finite sequence.

Proof

We use the same tricks that we have used before. Suppose that (A_1, A_2, \dots) is a σ -finite sequence for μ .

1. Let $B_n = \bigcup_{i=1}^n A_i$. Then $B_n \in \mathcal{A}$ for $n \in \mathbb{N}_+$ and this sequence is increasing. Moreover, $\mu(B_n) \leq \sum_{i=1}^n \mu(A_i) < \infty$ for $n \in \mathbb{N}_+$ and $\bigcup_{n=1}^{\infty} B_n = \bigcup_{n=1}^{\infty} A_n = S$.
2. Let $C_1 = A_1$ and let $C_n = A_n \setminus \bigcup_{i=1}^{n-1} A_i$ for $n \in \{2, 3, \dots\}$. Then $C_n \in \mathcal{A}$ for each $n \in \mathbb{N}_+$ and this sequence is disjoint. Moreover, $C_n \subseteq A_n$ so $\mu(C_n) \leq \mu(A_n) < \infty$ and $\bigcup_{n=1}^{\infty} C_n = \bigcup_{n=1}^{\infty} A_n = S$.

Extension and Uniqueness Theorems

The fundamental theorem on measures states that a positive, σ -finite measure μ on an algebra \mathcal{A} can be uniquely extended to $\sigma(\mathcal{A})$. The extension part is sometimes referred to as the *Carathéodory extension theorem*, and is named for the Greek mathematician Constantin Carathéodory.

If μ is a positive, σ -finite measure on an algebra \mathcal{A} , then μ can be extended to a positive measure on $\mathcal{S} = \sigma(\mathcal{A})$.

Proof

The proof is complicated, but here is a broad outline. First, for $A \subseteq S$, we define a *cover* of A to be a countable collection $\{A_i : i \in I\}$ of sets in \mathcal{A} such that $A \subseteq \bigcup_{i \in I} A_i$. Next, we define a new set function μ^* , the *outer measure*, on all subsets of S :

$$\mu^*(A) = \inf \left\{ \sum_{i \in I} \mu(A_i) : \{A_i : i \in I\} \text{ is a cover of } A \right\}, \quad A \subseteq S \quad (2.8.10)$$

Outer measure satisfies the following properties.

1. $\mu^*(A) \geq 0$ for $A \subseteq S$, so μ^* is nonnegative.
2. $\mu^*(A) = \mu(A)$ for $A \in \mathcal{A}$, so μ^* extends μ .
3. If $A \subseteq B$ then $\mu^*(A) \leq \mu^*(B)$, so μ^* is increasing.
4. If $A_i \subseteq S$ for each i in a countable index set I then $\mu^*\left(\bigcup_{i \in I} A_i\right) \leq \sum_{i \in I} \mu^*(A_i)$, so μ^* is countably subadditive.

Next, $A \subseteq S$ is said to be *measurable* if

$$\mu^*(B) = \mu^*(B \cap A) + \mu^*(B \setminus A), \quad B \subseteq S \quad (2.8.11)$$

Thus, A is measurable if μ^* is additive with respect to the partition of B induced by $\{A, A^c\}$, for every $B \subseteq S$. We let \mathcal{M} denote the collection of measurable subsets of S . The proof is finished by showing that $\mathcal{A} \subseteq \mathcal{M}$, \mathcal{M} is a σ -algebra of subsets of S , and μ^* is a positive measure on \mathcal{M} . It follows that $\sigma(\mathcal{A}) = \mathcal{S} \subseteq \mathcal{M}$ and hence μ^* is a measure on \mathcal{S} that extends μ .

Our next goal is the basic uniqueness result, which serves as the complement to the basic extension result. But first we need another variation of the term σ -finite.

Suppose that μ is a measure on a σ -algebra \mathcal{S} of subsets of S and $\mathcal{B} \subseteq \mathcal{S}$. Then μ is σ -finite on \mathcal{B} if there exists a countable collection $\{B_i : i \in I\} \subseteq \mathcal{B}$ such that $\mu(B_i) < \infty$ for $i \in I$ and $\bigcup_{i \in I} B_i = S$.

The next result is the uniqueness theorem. The proof, like others that we have seen, uses Dynkin's π - λ theorem, named for Eugene Dynkin.

Suppose that \mathcal{B} is a π -system and that $\mathcal{S} = \sigma(\mathcal{B})$. If μ_1 and μ_2 are positive measures on \mathcal{S} and are σ -finite on \mathcal{B} , and if $\mu_1(A) = \mu_2(A)$ for all $A \in \mathcal{B}$, then $\mu_1(A) = \mu_2(A)$ for all $A \in \mathcal{S}$.

Proof

Suppose that $B \in \mathcal{B}$ and that $\mu_1(B) = \mu_2(B) < \infty$. Let $\mathcal{L}_B = \{A \in \mathcal{S} : \mu_1(A \cap B) = \mu_2(A \cap B)\}$. Then $S \in \mathcal{L}_B$ since $\mu_1(B) = \mu_2(B)$. If $A \in \mathcal{L}_B$ then $\mu_1(A \cap B) = \mu_2(A \cap B)$ so $\mu_1(A^c \cap B) = \mu_1(B) - \mu_1(A \cap B) = \mu_2(B) - \mu_2(A \cap B) = \mu_2(A^c \cap B)$ and hence $A^c \in \mathcal{L}_B$. Finally, suppose that $\{A_j : j \in J\}$ is a countable, disjoint collection of events in \mathcal{L}_B . Then $\mu_1(A_j \cap B) = \mu_2(A_j \cap B)$ for each $j \in J$ and hence

$$\mu_1 \left[\left(\bigcup_{j \in J} A_j \right) \cap B \right] = \mu_1 \left(\bigcup_{j \in J} (A_j \cap B) \right) = \sum_{j \in J} \mu_1(A_j \cap B) \quad (2.8.12)$$

$$= \sum_{j \in J} \mu_2(A_j \cap B) = \mu_2 \left(\bigcup_{j \in J} (A_j \cap B) \right) = \mu_2 \left[\left(\bigcup_{j \in J} A_j \right) \cap B \right] \quad (2.8.13)$$

Therefore $\bigcup_{j \in J} A_j \in \mathcal{L}_B$, and so \mathcal{L}_B is a λ -system. By assumption, $\mathcal{B} \subseteq \mathcal{L}_B$ and therefore by the π - λ theorem, $\mathcal{S} = \sigma(\mathcal{B}) \subseteq \mathcal{L}_B$.

Next, by assumption there exists $B_i \in \mathcal{B}$ with $\mu_1(B_i) = \mu_2(B_i) < \infty$ for each $i \in \mathbb{N}_+$ and $S = \bigcup_{i=1}^{\infty} B_i$. If $A \in \mathcal{S}$ then the inclusion-exclusion rule can be applied to

$$\mu_k \left[\left(\bigcup_{i=1}^n B_i \right) \cap A \right] = \mu_k \left[\bigcup_{i=1}^n (A \cap B_i) \right] \quad (2.8.14)$$

where $k \in \{1, 2\}$ and $n \in \mathbb{N}_+$. But the inclusion-exclusion formula only has terms of the form $\mu_k \left[\bigcap_{j \in J} (A \cap B_j) \right] = \mu_k \left[A \cap \left(\bigcap_{j \in J} B_j \right) \right]$ where $J \subseteq \{1, 2, \dots, n\}$. But $\bigcap_{j \in J} B_j \in \mathcal{B}$ since \mathcal{B} is a π -system, so by the previous paragraph, $\mu_1 \left[\bigcap_{j \in J} (A \cap B_j) \right] = \mu_2 \left[\bigcap_{j \in J} (A \cap B_j) \right]$. It then follows that for each $n \in \mathbb{N}_+$

$$\mu_1 \left[\left(\bigcup_{i=1}^n B_i \right) \cap A \right] = \mu_2 \left[\left(\bigcup_{i=1}^n B_i \right) \cap A \right] \quad (2.8.15)$$

Finally, letting $n \rightarrow \infty$ and using the continuity theorem for increasing sets gives $\mu_1(A) = \mu_2(A)$.

An algebra \mathcal{A} of subsets of S is trivially a π -system. Hence, if μ_1 and μ_2 are positive measures on $\mathcal{S} = \sigma(\mathcal{A})$ and are σ -finite on \mathcal{A} , and if $\mu_1(A) = \mu_2(A)$ for $A \in \mathcal{A}$, then $\mu_1(A) = \mu_2(A)$ for $A \in \mathcal{S}$. This completes the second part of the fundamental theorem.

Of course, the results of this subsection hold for probability measures. Formally, a probability measure \mathbb{P} on an algebra \mathcal{A} of subsets of S is a positive measure on \mathcal{A} with the additional requirement that $\mathbb{P}(S) = 1$. Probability measures are trivially σ -finite, so a probability measure \mathbb{P} on an algebra \mathcal{A} can be uniquely extended to $\mathcal{S} = \sigma(\mathcal{A})$.

However, usually we start with a collection that is more primitive than an algebra. The next result combines the definition with the main theorem associated with the definition. For a proof see the section on Special Set Structures in the chapter on Foundations.

Suppose that \mathcal{B} is a nonempty collection of subsets of S and let

$$\mathcal{A} = \left\{ \bigcup_{i \in I} B_i : \{B_i : i \in I\} \text{ is a finite, disjoint collection of sets in } \mathcal{B} \right\} \quad (2.8.16)$$

If the following conditions are satisfied, then \mathcal{B} is a *semi-algebra* of subsets of S , and then \mathcal{A} is the algebra generated by \mathcal{B} .

1. If $B_1, B_2 \in \mathcal{B}$ then $B_1 \cap B_2 \in \mathcal{B}$.
2. If $B \in \mathcal{B}$ then $B^c \in \mathcal{A}$.

Suppose now that we know how a measure μ should work on a semi-algebra \mathcal{B} that generates an algebra \mathcal{A} and then a σ -algebra $\mathcal{S} = \sigma(\mathcal{A}) = \sigma(\mathcal{B})$. That is, we know $\mu(B) \in [0, \infty]$ for each $B \in \mathcal{B}$. Because of the additivity property, there is no question as to how we should extend μ to \mathcal{A} . We must have

$$\mu(A) = \sum_{i \in I} \mu(B_i) \quad (2.8.17)$$

if $A = \bigcup_{i \in I} B_i$ for some finite, disjoint collection $\{B_i : i \in I\}$ of sets in \mathcal{B} (so that $A \in \mathcal{A}$). However, we cannot assign the values $\mu(B)$ for $B \in \mathcal{B}$ arbitrarily. The following extension theorem states that, subject just to some essential consistency conditions, the extension of μ from the semi-algebra \mathcal{B} to the algebra \mathcal{A} does in fact produce a measure on \mathcal{A} . The consistency conditions are that μ be *finitely additive* and *countably subadditive* on \mathcal{B} .

Suppose that \mathcal{B} is a semi-algebra of subsets of S and that \mathcal{A} is the algebra of subsets of S generated by \mathcal{B} . A function $\mu : \mathcal{B} \rightarrow [0, \infty]$ can be uniquely extended to a measure on \mathcal{A} if and only if μ satisfies the following properties:

1. If $\emptyset \in \mathcal{B}$ then $\mu(\emptyset) = 0$.
2. If $\{B_i : i \in I\}$ is a finite, disjoint collection of sets in \mathcal{B} and $B = \bigcup_{i \in I} B_i \in \mathcal{B}$ then $\mu(B) = \sum_{i \in I} \mu(B_i)$.
3. If $B \in \mathcal{B}$ and $B \subseteq \bigcup_{i \in I} B_i$ where $\{B_i : i \in I\}$ is a countable collection of sets in \mathcal{B} then $\mu(B) \leq \sum_{i \in I} \mu(B_i)$.

If the measure μ on the algebra \mathcal{A} is σ -finite, then the [extension theorem](#) and the [uniqueness theorem](#) apply, so μ can be extended uniquely to a measure on the σ -algebra $\mathcal{S} = \sigma(\mathcal{A}) = \sigma(\mathcal{B})$. This chain of extensions, starting with a semi-algebra \mathcal{B} , is often how measures are constructed.

Examples and Applications

Product Spaces

Suppose that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces. For the Cartesian product set $S \times T$, recall that the *product σ -algebra* is

$$\mathcal{S} \otimes \mathcal{T} = \sigma\{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\} \quad (2.8.18)$$

the σ -algebra generated by the Cartesian products of measurable sets, sometimes referred to as *measurable rectangles*.

Suppose that (S, \mathcal{S}, μ) and (T, \mathcal{T}, ν) are σ -finite measure spaces. Then there exists a unique σ -finite measure $\mu \otimes \nu$ on $(S \times T, \mathcal{S} \otimes \mathcal{T})$ such that

$$(\mu \otimes \nu)(A \times B) = \mu(A)\nu(B); \quad A \in \mathcal{S}, B \in \mathcal{T} \quad (2.8.19)$$

The measure space $(S \times T, \mathcal{S} \otimes \mathcal{T}, \mu \otimes \nu)$ is the *product measure space* associated with (S, \mathcal{S}, μ) and (T, \mathcal{T}, ν) .

Proof

Recall that the collection $\mathcal{B} = \{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\}$ is a semi-algebra: the intersection of two product sets is another product set, and the complement of a product set is the union of two disjoint product sets. We define $\rho : \mathcal{B} \rightarrow [0, \infty]$ by $\rho(A \times B) = \mu(A)\nu(B)$. The [consistency conditions](#) hold, so ρ can be extended to a measure on the algebra \mathcal{A} generated by \mathcal{B} . The algebra \mathcal{A} is the collection of all finite, disjoint unions of products of measurable sets. We will now show that the extended measure ρ is σ -finite on \mathcal{A} . Since μ is σ -finite, [there exists](#), an increasing sequence (A_1, A_2, \dots) of sets in \mathcal{S} with $\mu(A_i) < \infty$ and $\bigcup_{i=1}^{\infty} A_i = S$. Similarly, there exists an increasing sequence (B_1, B_2, \dots) of sets in \mathcal{T} with $\nu(B_j) < \infty$ and $\bigcup_{j=1}^{\infty} B_j = T$. Then $\rho(A_i \times B_j) = \mu(A_i)\nu(B_j) < \infty$, and since the sets are increasing, $\bigcup_{(i,j) \in \mathbb{N}_+ \times \mathbb{N}_+} A_i \times B_j = S \times T$. The standard [extension theorem](#) and uniqueness theorem [uniqueness theorem](#) now apply, so ρ can be extended uniquely to a measure on $\sigma(\mathcal{A}) = \mathcal{S} \otimes \mathcal{T}$.

Recall that for $C \subseteq S \times T$, the cross section of C in the first coordinate at $x \in S$ is $C_x = \{y \in T : (x, y) \in C\}$. Similarly, the cross section of C in the second coordinate at $y \in T$ is $C^y = \{x \in S : (x, y) \in C\}$. We know that the cross sections of a measurable set are measurable. The following result shows that the measures of the cross sections of a measurable set form measurable functions.

Suppose again that (S, \mathcal{S}, μ) and (T, \mathcal{T}, ν) are σ -finite measure spaces. If $C \in \mathcal{S} \otimes \mathcal{T}$ then

1. $x \mapsto \nu(C_x)$ is a measurable function from S to $[0, \infty]$.
2. $y \mapsto \mu(C^y)$ is a measurable function from T to $[0, \infty]$.

Proof

We prove part (a), since of course the proof for part (b) is symmetric. Suppose first that the measure spaces are finite. Let $\mathcal{R} = \{A \times B : A \in \mathcal{S}, B \in \mathcal{T}\}$ denote the set of measurable rectangles. Let $\mathcal{C} = \{C \in \mathcal{S} \otimes \mathcal{T} : x \mapsto \nu(C_x) \text{ is measurable}\}$. If $A \times B \in \mathcal{R}$, then $A \times B \in \mathcal{C}$, since $\nu[(A \times B)_x] = \nu(B)\mathbf{1}_A(x)$. Next, suppose $C \in \mathcal{C}$. Then $(C^c)_x = (C_x)^c$, so $\nu[(C^c)_x] = \nu(T) - \nu(C_x)$ and this is a measurable function of $x \in S$. Hence $C^c \in \mathcal{C}$. Next, suppose that $\{C_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{C} and let $C = \bigcup_{i \in I} C_i$. Then $\{(C_i)_x : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{T} , and $C_x = \bigcup_{i \in I} (C_i)_x$. Hence $\nu(C_x) = \sum_{i \in I} \nu[(C_i)_x]$, and this is a measurable function of $x \in S$. Hence $C \in \mathcal{C}$. It follows that \mathcal{C} is a λ -system that contains \mathcal{R} , which in turn is a π -system. It follows from Dynkin's π - λ theorem, that $\mathcal{S} \otimes \mathcal{T} = \sigma(\mathcal{R}) \subseteq \mathcal{C}$. Thus $\mathcal{C} = \mathcal{S} \otimes \mathcal{T}$.

Consider now the general case where the measure spaces are σ -finite. There exists a countable, increasing sequence of sets $C_n \in \mathcal{S} \otimes \mathcal{T}$ for $n \in \mathbb{N}_+$ with $(\mu \otimes \nu)(C_n) < \infty$ for $n \in \mathbb{N}_+$. If $C \in \mathcal{S} \otimes \mathcal{T}$, then $C \cap C_n$ is increasing in $n \in \mathbb{N}_+$, and $C = \bigcup_{n=1}^{\infty} (C \cap C_n)$. Hence, for $x \in S$, $(C \cap C_n)_x$ is increasing in $n \in \mathbb{N}_+$ and $C_x = \bigcup_{n=1}^{\infty} (C \cap C_n)_x$. Therefore $\nu(C_x) = \lim_{n \rightarrow \infty} \nu[(C \cap C_n)_x]$. But $x \mapsto \nu[(C \cap C_n)_x]$ is a measurable function of $x \in S$ for each $n \in \mathbb{N}_+$ by the previous argument, so $x \mapsto \nu(C_x)$ is a measurable function of $x \in S$.

In the next chapter, where we study integration with respect to a measure, we will see that for $C \in \mathcal{S} \otimes \mathcal{T}$, the product measure $(\mu \otimes \nu)(C)$ can be computed by integrating $\nu(C_x)$ over $x \in S$ with respect to μ or by integrating $\mu(C^y)$ over $y \in T$ with respect to ν . These results, generalizing the definition of the [product measure](#), are special cases of Fubini's theorem, named for the Italian mathematician Guido Fubini.

Except for more complicated notation, these results extend in a perfectly straightforward way to the product of a finite number of σ -finite measure spaces.

Suppose that $n \in \mathbb{N}_+$ and that $(S_i, \mathcal{S}_i, \mu_i)$ is a σ -finite measure space for $i \in \{1, 2, \dots, n\}$. Let $S = \prod_{i=1}^n S_i$ and let \mathcal{S} denote the corresponding product σ -algebra. There exists a unique σ -finite measure μ on (S, \mathcal{S}) satisfying

$$\mu \left(\prod_{i=1}^n A_i \right) = \prod_{i=1}^n \mu_i(A_i), \quad A_i \in \mathcal{S}_i \text{ for } i \in \{1, 2, \dots, n\} \quad (2.8.20)$$

The measure space (S, \mathcal{S}, μ) is the *product measure space* associated with the given measure spaces.

Lebesgue Measure

The next discussion concerns our most important and essential application. Recall that the *Borel* σ -algebra on \mathbb{R} , named for Émile Borel, is the σ -algebra \mathcal{B} generated by the standard Euclidean topology on \mathbb{R} . Equivalently, $\mathcal{B} = \sigma(\mathcal{I})$ where \mathcal{I} is the collection of intervals of \mathbb{R} (of all types—bounded and unbounded, with any type of closure, and including single points and the empty set). Next recall how the *length* of an interval is defined. For $a, b \in \mathbb{R}$ with $a \leq b$, each of the intervals (a, b) , $[a, b)$, $(a, b]$, and $[a, b]$ has length $b - a$. For $a \in \mathbb{R}$, each of the intervals (a, ∞) , $[a, \infty)$, $(-\infty, a)$, $(-\infty, a]$ has length ∞ , as does \mathbb{R} itself. The standard measure on \mathcal{B} generalizes the length measurement for intervals.

There exists a unique measure λ on \mathcal{B} such that $\lambda(I) = \text{length}(I)$ for $I \in \mathcal{I}$. The measure λ is *Lebesgue measure* on $(\mathbb{R}, \mathcal{B})$.

Proof

Recall that \mathcal{I} is a semi-algebra: The intersection of two intervals is another interval, and the complement of an interval is either another interval or the union of two disjoint intervals. Define λ on \mathcal{I} by $\lambda(I) = \text{length}(I)$ for $I \in \mathcal{I}$. Then λ satisfies

the [consistency condition](#) and hence λ can be extended to a measure on the algebra \mathcal{J} generated by \mathcal{I} , namely the collection of finite, disjoint unions of intervals. The measure λ on \mathcal{J} is clearly σ -finite, since \mathbb{R} can be written as a countably infinite union of bounded intervals. Hence the standard [extension theorem](#) and [uniqueness theorem](#) apply, so λ can be extended to a measure on $\mathcal{R} = \sigma(\mathcal{J})$.

The is name in honor of Henri Lebesgue, of course. Since λ is σ -finite, the σ -algebra of Borel sets \mathcal{R} can be completed with respect to λ .

The completion of the Borel σ -algebra \mathcal{R} with respect to λ is the *Lebesgue σ -algebra* \mathcal{R}^* .

Recall that *completed* means that if $A \in \mathcal{R}^*$, $\lambda(A) = 0$ and $B \subseteq A$, then $B \in \mathcal{R}^*$ (and then $\lambda(B) = 0$). The Lebesgue measure λ on \mathbb{R} , with either the Borel σ -algebra \mathcal{R} , or its completion \mathcal{R}^* is the standard measure that is used for the real numbers. Other properties of the measure space $(\mathbb{R}, \mathcal{R}, \lambda)$ are given below, in the discussion of Lebesgue measure on \mathbb{R}^n .

For $n \in \mathbb{N}_+$, let \mathcal{R}_n denote the Borel σ -algebra corresponding to the the standard Euclidean topology on \mathbb{R}^n , so that $(\mathbb{R}^n, \mathcal{R}_n)$ is the n -dimensional Euclidean measurable space. The σ -algebra, \mathcal{R}_n is also the n -fold power of \mathcal{R} , the Borel σ -algebra of \mathbb{R} . That is, $\mathcal{R}_n = \mathcal{R} \otimes \mathcal{R} \otimes \cdots \otimes \mathcal{R}$ (n times). It is also the σ -algebra generated by the products of intervals:

$$\mathcal{R}_n = \sigma \{ I_1 \times I_2 \times \cdots \times I_n : I_j \in \mathcal{I} \text{ for } j \in \{1, 2, \dots, n\} \} \quad (2.8.21)$$

As above, let λ denote Lebesgue measure on $(\mathbb{R}, \mathcal{R})$.

For $n \in \mathbb{N}_+$ the n -fold power of λ , denoted λ_n is *Lebesgue measure* on $(\mathbb{R}^n, \mathcal{R}_n)$. In particular,

$$\lambda_n(A_1 \times A_2 \times \cdots \times A_n) = \lambda(A_1)\lambda(A_2) \cdots \lambda(A_n); \quad A_1, \dots, A_n \in \mathcal{R} \quad (2.8.22)$$

Specializing further, if $I_j \in \mathcal{I}$ is an interval for $j \in \{1, 2, \dots, n\}$ then

$$\lambda_n(I_1 \times I_2 \times \cdots \times I_n) = \text{length}(I_1)\text{length}(I_2) \cdots \text{length}(I_n) \quad (2.8.23)$$

In particular, λ_2 extends the *area* measure on \mathcal{R}_2 and λ_3 extends the *volume* measure on \mathcal{R}_3 . In general, $\lambda_n(A)$ is sometimes referred to as *n -dimensional volume* of $A \in \mathcal{R}_n$. As in the one-dimensional case, \mathcal{R}_n can be completed with respect to λ_n , essentially adding all subsets of sets of measure 0 to \mathcal{R}_n . The completed σ -algebra is the σ -algebra of *Lebesgue measurable* sets. Since $\lambda_n(U) > 0$ if $U \subseteq \mathbb{R}^n$ is open, the support of λ_n is all of \mathbb{R}^n . In addition, Lebesgue measure has the regularity properties that are concerned with approximating the measure of a set, from below with the measure of a compact set, and from above with the measure of an open set.

The measure space $(\mathbb{R}^n, \mathcal{R}_n, \lambda_n)$ is *regular*. That is, for $A \in \mathcal{R}_n$,

1. $\lambda_n(A) = \sup\{\lambda_n(C) : C \text{ is compact and } C \subseteq A\}$, (*inner regularity*)
2. $\lambda_n(A) = \inf\{\lambda_n(U) : U \text{ is open and } A \subseteq U\}$ (*outer regularity*).

The following theorem describes how the measure of a set is changed under certain basic transformations. These are essential properties of Lebesgue measure. To setup the notation, suppose that $n \in \mathbb{N}_+$, $A \subseteq \mathbb{R}^n$, $x \in \mathbb{R}^n$, $c \in (0, \infty)$ and that T is an $n \times n$ matrix. Define

$$A + x = \{a + x : a \in A\}, \quad cA = \{ca : a \in A\}, \quad TA = \{Ta : a \in A\} \quad (2.8.24)$$

Suppose that $A \in \mathcal{R}_n$.

1. If $x \in \mathbb{R}^n$ then $\lambda_n(A + x) = \lambda_n(A)$ (*translation invariance*)
2. If $c \in (0, \infty)$ then $\lambda_n(cA) = c^n \lambda_n(A)$ (*dilation property*)
3. If T is an $n \times n$ matrix then $\lambda_n(TA) = |\det(T)| \lambda_n(A)$ (*the scaling property*)

Lebesgue-Stieltjes Measures on \mathbb{R}

The construction of Lebesgue measure on \mathbb{R} can be generalized. Here is the definition that we will need.

A function $F : \mathbb{R} \rightarrow \mathbb{R}$ that satisfies the following properties is a *distribution function* on \mathbb{R}

1. F is increasing: if $x \leq y$ then $F(x) \leq F(y)$.
2. F is continuous from the right: $\lim_{t \downarrow x} F(t) = F(x)$ for all $x \in \mathbb{R}$.

Since F is increasing, the limit from the left at $x \in \mathbb{R}$ exists in \mathbb{R} and is denoted $F(x^-) = \lim_{t \uparrow x} F(t)$. Similarly $F(\infty) = \lim_{x \rightarrow \infty} F(x)$ exists, as a real number or ∞ , and $F(-\infty) = \lim_{x \rightarrow -\infty} F(x)$ exists, as a real number or $-\infty$.

If F is a distribution function on \mathbb{R} , then there exists a unique measure μ on \mathcal{R} that satisfies

$$\mu(a, b] = F(b) - F(a), \quad -\infty \leq a \leq b \leq \infty \quad (2.8.25)$$

The measure μ is called the *Lebesgue-Stieltjes measure* associated with F , named for Henri Lebesgue and Thomas Joannes Stieltjes. Distribution functions and the measures associated with them are studied in more detail in the chapter on Distributions. When the function F takes values in $[0, 1]$, the associated measure \mathbb{P} is a probability measure, and the function F is the *probability distribution function* of \mathbb{P} . Probability distribution functions are also studied in much more detail (but with less technicality) in the chapter on Distributions.

Note that the identity function $x \mapsto x$ for $x \in \mathbb{R}$ is a distribution function, and the measure associated with this function is ordinary Lebesgue measure on \mathbb{R} constructed in (15).

2.9: Probability Spaces Revisited

In this section we discuss probability spaces from the more advanced point of view of measure theory. The previous two sections on positive measures and existence and uniqueness are prerequisites. The discussion is divided into two parts: first those concepts that are shared rather equally between probability theory and general measure theory, and second those concepts that are for the most part unique to probability theory. In particular, it's a mistake to think of probability theory as a mere branch of measure theory. Probability has its own notation, terminology, point of view, and applications that makes it an incredibly rich subject on its own.

Basic Concepts

Our first discussion concerns topics that were discussed in the section on positive measures. So no proofs are necessary, but you will notice that the notation, and in some cases the terminology, is very different.

Definitions

We can now give a precise definition of the probability space, the mathematical model of a random experiment.

A *probability space* $(S, \mathcal{S}, \mathbb{P})$, consists of three essential parts:

1. A set of outcomes S .
2. A σ -algebra of events \mathcal{S} .
3. A probability measure \mathbb{P} on the *sample space* (S, \mathcal{S}) .

Often the special notation $(\Omega, \mathcal{F}, \mathbb{P})$ is used for a probability space in the literature—the symbol Ω for the set of outcomes is intended to remind us that these are *all* possible outcomes. However in this text, we don't insist on the special notation, and use whatever notation seems most appropriate in a given context.

In probability, σ -algebras are not just important for theoretical and foundational purposes, but are important for practical purposes as well. A σ -algebra can be used to specify *partial information* about an experiment—a concept of fundamental importance. Specifically, suppose that \mathcal{A} is a collection of events in the experiment, and that we know whether or not A occurred for each $A \in \mathcal{A}$. Then in fact, we can determine whether or not A occurred for each $A \in \sigma(\mathcal{A})$, the σ -algebra generated by \mathcal{A} .

Technically, a random variable for our experiment is a *measurable* function from the sample space into another measurable space.

Suppose that $(S, \mathcal{S}, \mathbb{P})$ is a probability space and that (T, \mathcal{T}) is another measurable space. A *random variable* X with values in T is a measurable function from S into T .

1. The *probability distribution* of X is the mapping on \mathcal{T} given by $B \mapsto \mathbb{P}(X \in B)$.
2. The collection of events $\{X \in B : B \in \mathcal{T}\}$ is a sub σ -algebra of \mathcal{S} , and is the σ -algebra generated by X , denoted $\sigma(X)$.

Details

Figure 2.9.1: The event $\{X \in B\}$ associated with $B \in \mathcal{T}$

If we observe the value of X , then we know whether or not each event in $\sigma(X)$ has occurred. More generally, we can construct the σ -algebra associated with any collection of random variables.

suppose that (T_i, \mathcal{T}_i) is a measurable space for each i in an index set I , and that X_i is a random variable taking values in T_i for each $i \in I$. The σ -algebra generated by $\{X_i : i \in I\}$ is

$$\sigma\{X_i : i \in I\} = \sigma\{X \in B_i : B_i \in \mathcal{T}_i, i \in I\} \quad (2.9.1)$$

If we observe the value of X_i for each $i \in I$ then we know whether or not each event in $\sigma\{X_i : i \in I\}$ has occurred. This idea is very important in the study of stochastic processes.

Null Events, Almost Sure Events, and Equivalence

Suppose that $(S, \mathcal{S}, \mathbb{P})$ is a probability space.

Define the following collections of events:

1. $\mathcal{N} = \{A \in \mathcal{S} : \mathbb{P}(A) = 0\}$, the collection of *null* events
2. $\mathcal{M} = \{A \in \mathcal{S} : \mathbb{P}(A) = 1\}$, the collection of *almost sure* events
3. $\mathcal{D} = \mathcal{N} \cup \mathcal{M} = \{A \in \mathcal{S} : \mathbb{P}(A) = 0 \text{ or } \mathbb{P}(A) = 1\}$, the collection of *essentially deterministic* events

The collection of essentially deterministic events \mathcal{D} is a sub σ -algebra of \mathcal{S} .

In the section on independence, we showed that \mathcal{D} is also a collection of independent events.

Intuitively, equivalent events or random variables are those that are indistinguishable from a probabilistic point of view. Recall first that the *symmetric difference* between events A and B is $A \triangle B = (A \setminus B) \cup (B \setminus A)$; it is the event that occurs if and only if one of the events occurs, but not the other, and corresponds to *exclusive or*. Here is the definition for events:

Events A and B are *equivalent* if $A \triangle B \in \mathcal{N}$, and we denote this by $A \equiv B$. The relation \equiv is an equivalence relation on \mathcal{S} . That is, for $A, B, C \in \mathcal{S}$,

1. $A \equiv A$ (the *reflexive property*).
2. If $A \equiv B$ then $B \equiv A$ (the *symmetric property*).
3. If $A \equiv B$ and $B \equiv C$ then $A \equiv C$ (the *transitive property*).

Thus $A \equiv B$ if and only if $\mathbb{P}(A \triangle B) = \mathbb{P}(A \setminus B) + \mathbb{P}(B \setminus A) = 0$ if and only if $\mathbb{P}(A \setminus B) = \mathbb{P}(B \setminus A) = 0$. The equivalence relation \equiv partitions \mathcal{S} into disjoint classes of mutually equivalent events. Equivalence is preserved under the set operations.

Suppose that $A, B \in \mathcal{S}$. If $A \equiv B$ then $A^c \equiv B^c$.

Suppose that $A_i, B_i \in \mathcal{S}$ for i in a countable index set I . If $A_i \equiv B_i$ for $i \in I$ then

1. $\bigcup_{i \in I} A_i \equiv \bigcup_{i \in I} B_i$
2. $\bigcap_{i \in I} A_i \equiv \bigcap_{i \in I} B_i$

Equivalent events have the same probability.

If $A, B \in \mathcal{S}$ and $A \equiv B$ then $\mathbb{P}(A) = \mathbb{P}(B)$.

The converse trivially fails, and a [counterexample](#) is given below. However, the null and almost sure events do form equivalence classes.

Suppose that $A \in \mathcal{S}$.

1. If $A \in \mathcal{N}$ then $A \equiv B$ if and only if $B \in \mathcal{N}$.
2. If $A \in \mathcal{M}$ then $A \equiv B$ if and only if $B \in \mathcal{M}$.

We can extend the notion of equivalence to random variables taking values in the same space. Thus suppose that (T, \mathcal{T}) is another measurable space. If X and Y are random variables with values in T , then (X, Y) is a random variable with values in $T \times T$, which is given the usual product σ -algebra $\mathcal{T} \otimes \mathcal{T}$. We assume that the diagonal set $D = \{(x, x) : x \in T\} \in \mathcal{T} \otimes \mathcal{T}$, which is almost always true in applications.

Random variables X and Y taking values in T are *equivalent* if $\mathbb{P}(X = Y) = 1$. Again we write $X \equiv Y$. The relation \equiv is an equivalence relation on the collection of random variables that take values in T . That is, for random variables X, Y , and Z with values in T ,

1. $X \equiv X$ (the *reflexive property*).
2. If $X \equiv Y$ then $Y \equiv X$ (the *symmetric property*).
3. If $X \equiv Y$ and $Y \equiv Z$ then $X \equiv Z$ (the *transitive property*).

So the collection of random variables with values in T is partitioned into disjoint classes of mutually equivalent variables.

Suppose that X and Y are random variables taking values in T and that $X \equiv Y$. Then

1. $\{X \in B\} \equiv \{Y \in B\}$ for every $B \in \mathcal{T}$.
2. X and Y have the same probability distribution on (T, \mathcal{T}) .

Again, the converse to part (b) fails with a passion, and a [counterexample](#) is given below. It often happens that a definition for random variables subsumes the corresponding definition for events, by considering the indicator variables of the events. So it is with equivalence.

Suppose that $A, B \in \mathcal{S}$. Then $A \equiv B$ if and only if $\mathbf{1}_A \equiv \mathbf{1}_B$.

Equivalence is preserved under a deterministic transformation of the variables. For the next result, suppose that (U, \mathcal{U}) is yet another measurable space, along with (T, \mathcal{T}) .

Suppose X, Y are random variables with values in T and that $g: T \rightarrow U$ is measurable. If $X \equiv Y$ then $g(X) \equiv g(Y)$.

Suppose again that $(S, \mathcal{S}, \mathbb{P})$ is a probability space corresponding to a random experiment. Let \mathcal{V} denote the collection of all real-valued random variables for the experiment, that is, all measurable functions from S into \mathbb{R} . With the usual definitions of addition and scalar multiplication, $(\mathcal{V}, +, \cdot)$ is a vector space. However, in probability theory, we often do not want to distinguish between random variables that are equivalent, so it's nice to know that the vector space structure is preserved when we *identify* equivalent random variables. Formally, let $[X]$ denote the equivalence class generated by a real-valued random variable $X \in \mathcal{V}$, and let \mathcal{W} denote the collection of all such equivalence classes. In modular notation, \mathcal{W} is the set \mathcal{V} / \equiv . We define addition and scalar multiplication on \mathcal{W} by

$$[X] + [Y] = [X + Y], \quad c[X] = [cX]; \quad [X], [Y] \in \mathcal{W}, \quad c \in \mathbb{R} \quad (2.9.2)$$

$(\mathcal{W}, +, \cdot)$ is a vector space.

Often we don't bother to use the special notation for the equivalence class associated with a random variable. Rather, it's understood that equivalent random variables represent the same object. Spaces of functions in a general measure space are studied in the chapter on Distributions, and spaces of random variables are studied in more detail in the chapter on Expected Value.

Completion

Suppose again that $(S, \mathcal{S}, \mathbb{P})$ is a probability space, and that \mathcal{N} denotes the collection of null events, as above. Suppose that $A \in \mathcal{N}$ so that $\mathbb{P}(A) = 0$. If $B \subseteq A$ and $B \in \mathcal{S}$, then we know that $\mathbb{P}(B) = 0$ so $B \in \mathcal{N}$ also. However, in general there might be subsets of A that are not in \mathcal{S} . This leads naturally to the following definition.

The probability space $(S, \mathcal{S}, \mathbb{P})$ is *complete* if $A \in \mathcal{N}$ and $B \subseteq A$ imply $B \in \mathcal{S}$ (and hence $B \in \mathcal{N}$).

So the probability space is complete if every subset of an event with probability 0 is also an event (and hence also has probability 0). We know from our work on positive measures that every σ -finite measure space that is not complete can be completed. So in particular a probability space that is not complete can be completed. To review the construction, recall that the equivalence relation \equiv that we used above on \mathcal{S} is extended to $\mathcal{P}(S)$ (the power set of S).

For $A, B \subseteq S$, define $A \equiv B$ if and only if there exists $N \in \mathcal{N}$ such that $A \triangle B \subseteq N$. The relation \equiv is an equivalence relation on $\mathcal{P}(S)$.

Here is how the probability space is completed:

Let $\mathcal{S}_0 = \{A \subseteq S : A \equiv B \text{ for some } B \in \mathcal{S}\}$. For $A \in \mathcal{S}_0$, define $\mathbb{P}_0(A) = \mathbb{P}(B)$ where $B \in \mathcal{S}$ and $A \equiv B$. Then

1. \mathcal{S}_0 is a σ -algebra of subsets of S and $\mathcal{S} \subseteq \mathcal{S}_0$.
2. \mathbb{P}_0 is a probability measure on (S, \mathcal{S}_0) .
3. $(S, \mathcal{S}_0, \mathbb{P}_0)$ is complete, and is the *completion* of $(S, \mathcal{S}, \mathbb{P})$.

Product Spaces

Our next discussion concerns the construction of probability spaces that correspond to specified distributions. To set the stage, suppose that $(S, \mathcal{S}, \mathbb{P})$ is a probability space. If we let X denote the identity function on S , so that $X(x) = x$ for $x \in S$, then $\{X \in A\} = A$ for $A \in \mathcal{S}$ and hence $\mathbb{P}(X \in A) = \mathbb{P}(A)$. That is, \mathbb{P} is the probability distribution of X . We have seen this before—every probability measure can be thought of as the distribution of a random variable. The next result shows how to construct a probability space that corresponds to a sequence of independent random variables with specified distributions.

Suppose $n \in \mathbb{N}_+$ and that $(S_i, \mathcal{S}_i, \mathbb{P}_i)$ is a probability space for $i \in \{1, 2, \dots, n\}$. The corresponding product measure space $(S, \mathcal{S}, \mathbb{P})$ is a probability space. If $X_i: S \rightarrow S_i$ is the i th coordinate function on S so that $X_i(\mathbf{x}) = x_i$ for $\mathbf{x} = (x_1, x_2, \dots, x_n) \in S$ then (X_1, X_2, \dots, X_n) is a sequence of independent random variables on $(S, \mathcal{S}, \mathbb{P})$, and X_i has distribution \mathbb{P}_i on (S_i, \mathcal{S}_i) for each $i \in \{1, 2, \dots, n\}$.

Proof

Of course, the existence of the product space $(S, \mathcal{S}, \mathbb{P})$ follows immediately from the more general result for products of positive measure spaces. Recall that $S = \prod_{i=1}^n S_i$ and that \mathcal{S} is the σ -algebra generated by sets of the form $\prod_{i=1}^n A_i$ where $A_i \in \mathcal{S}_i$ for each $i \in \{1, 2, \dots, n\}$. Finally, \mathbb{P} is the unique positive measure on (S, \mathcal{S}) satisfying

$$\mathbb{P}\left(\prod_{i=1}^n A_i\right) = \prod_{i=1}^n \mathbb{P}_i(A_i) \quad (2.9.3)$$

where again, $A_i \in \mathcal{S}_i$ for each $i \in \{1, 2, \dots, n\}$. Clearly \mathbb{P} is a probability measure since $\mathbb{P}(S) = \prod_{i=1}^n \mathbb{P}_i(S_i) = 1$. Suppose that $A_i \in \mathcal{S}_i$ for $i \in \{1, 2, \dots, n\}$. Then $\{X_1 \in A_1, X_2 \in A_2, \dots, X_n \in A_n\} = \prod_{i=1}^n A_i \in \mathcal{S}$. Hence

$$\mathbb{P}(X_1 \in A_1, X_2 \in A_2, \dots, X_n \in A_n) = \prod_{i=1}^n \mathbb{P}_i(A_i) \quad (2.9.4)$$

If we fix $i \in \{1, 2, \dots, n\}$ and let $A_j = S_j$ for $j \neq i$, then the displayed equation give $\mathbb{P}(X_i \in A_i) = \mathbb{P}_i(A_i)$, so X_i has distribution \mathbb{P}_i on (S_i, \mathcal{S}_i) . Returning to the displayed equation we have

$$\mathbb{P}(X_1 \in A_1, X_2 \in A_2, \dots, X_n \in A_n) = \prod_{i=1}^n \mathbb{P}(X_i \in A_i) \quad (2.9.5)$$

so (X_1, X_2, \dots, X_n) are independent.

Intuitively, the given probability spaces correspond to n random experiments. The product space then is the probability space that corresponds to the experiments performed independently. When modeling a random experiment, if we say that we have a finite sequence of independent random variables with specified distributions, we can rest assured that there actually is a probability space that supports this statement

We can extend the last result to an infinite sequence of probability spaces. Suppose that (S_i, \mathcal{S}_i) is a measurable space for each $i \in \mathbb{N}_+$. Recall that the product space $\prod_{i=1}^{\infty} S_i$ consists of all sequences $\mathbf{x} = (x_1, x_2, \dots)$ such that $x_i \in S_i$ for each $i \in \mathbb{N}_+$. The corresponding product σ -algebra \mathcal{S} is generated by the collection of *cylinder sets*. That is, $\mathcal{S} = \sigma(\mathcal{B})$ where

$$\mathcal{B} = \left\{ \prod_{i=1}^{\infty} A_i : A_i \in \mathcal{S}_i \text{ for each } i \in \mathbb{N}_+ \text{ and } A_i = S_i \text{ for all but finitely many } i \in \mathbb{N}_+ \right\} \quad (2.9.6)$$

Suppose that $(S_i, \mathcal{S}_i, \mathbb{P}_i)$ is a probability space for $i \in \mathbb{N}_+$. Let (S, \mathcal{S}) denote the product measurable space so that $\mathcal{S} = \sigma(\mathcal{B})$ where \mathcal{B} is the collection of cylinder sets. Then there exists a unique probability measure \mathbb{P} on (S, \mathcal{S}) that satisfies

$$\mathbb{P}\left(\prod_{i=1}^{\infty} A_i\right) = \prod_{i=1}^{\infty} \mathbb{P}_i(A_i), \quad \prod_{i=1}^{\infty} A_i \in \mathcal{B} \quad (2.9.7)$$

If $X_i : S \rightarrow S_i$ is the i th coordinate function on S for $i \in \mathbb{N}_+$, so that $X_i(\mathbf{x}) = x_i$ for $\mathbf{x} = (x_1, x_2, \dots) \in S$, then (X_1, X_2, \dots) is a sequence of independent random variables on $(S, \mathcal{S}, \mathbb{P})$, and X_i has distribution \mathbb{P}_i on (S_i, \mathcal{S}_i) for each $i \in \mathbb{N}_+$.

Proof

The proof is similar to the one in for positive measure spaces in the section on existence and uniqueness. First recall that the collection of cylinder sets \mathcal{B} is a semi-algebra. We define $\mathbb{P} : \mathcal{B} \rightarrow [0, 1]$ as in the statement of the theorem. Note that all but finitely many factors are 1. The consistency conditions are satisfied, so \mathbb{P} can be extended to a probability measure on the algebra \mathcal{A} generated by \mathcal{B} . That is, \mathcal{A} is the collection of all finite, disjoint unions of cylinder sets. The standard extension theorem and uniqueness theorem now apply, so \mathbb{P} can be extended uniquely to a measure on $\mathcal{S} = \sigma(\mathcal{A})$. The proof that (X_1, X_2, \dots) are independent and that X_i has distribution \mathbb{P}_i for each $i \in \mathbb{N}_+$ is just as in the previous theorem.

Once again, if we model a random process by starting with an infinite sequence of independent random variables, we can be sure that there exists a probability space that supports this sequence. The particular probability space constructed in the last theorem is called the *canonical probability space* associated with the sequence of random variables. Note also that it was important that we had *probability measures* rather than just general positive measures in the construction, since the infinite product $\prod_{i=1}^{\infty} \mathbb{P}_i(A_i)$ is always well defined. The next section on Stochastic Processes continues the discussion of how to construct probability spaces that correspond to a collection of random variables with specified distributional properties.

Probability Concepts

Our next discussion concerns topics that are unique to probability theory and do not have simple analogies in general measure theory.

Independence

As usual, suppose that $(S, \mathcal{S}, \mathbb{P})$ is a probability space. We have already studied the independence of collections of events and the independence of collections of random variables. A more complete and general treatment results if we define the independence of collections of *collections* of events, and most importantly, the independence of collections of σ -algebras. This extension actually occurred already, when we went from independence of a collection of events to independence of a collection of random variables, but we did not note it at the time. In spite of the layers of set theory, the basic idea is the same.

Suppose that \mathcal{A}_i is a collection of events for each i in an index set I . Then $\mathcal{A} = \{\mathcal{A}_i : i \in I\}$ is independent if and only if for every choice of $A_i \in \mathcal{A}_i$ for $i \in I$, the collection of events $\{A_i : i \in I\}$ is independent. That is, for every finite $J \subseteq I$,

$$\mathbb{P}\left(\bigcap_{j \in J} A_j\right) = \prod_{j \in J} \mathbb{P}(A_j) \quad (2.9.8)$$

As noted above, independence of random variables, as we defined previously, is a special case of our new definition.

Suppose that (T_i, \mathcal{T}_i) is a measurable space for each i in an index set I , and that X_i is a random variable taking values in a set T_i for each $i \in I$. The independence of $\{X_i : i \in I\}$ is equivalent to the independence of $\{\sigma(X_i) : i \in I\}$.

Independence of events is also a special case of the new definition, and thus our new definition really does subsume our old one.

Suppose that A_i is an event for each $i \in I$. The independence of $\{A_i : i \in I\}$ is equivalent to the independence of $\{\mathcal{A}_i : i \in I\}$ where $\mathcal{A}_i = \sigma\{A_i\} = \{S, \emptyset, A_i, A_i^c\}$ for each $i \in I$.

For every collection of objects that we have considered (collections of events, collections of random variables, collections of collections of events), the notion of independence has the basic inheritance property.

Suppose that \mathcal{A} is a collection of collections of events.

1. If \mathcal{A} is independent then \mathcal{B} is independent for every $\mathcal{B} \subseteq \mathcal{A}$.
2. If \mathcal{B} is independent for every finite $\mathcal{B} \subseteq \mathcal{A}$ then \mathcal{A} is independent.

Our most important collections are σ -algebras, and so we are most interested in the independence of a collection of σ -algebras. The next result allows us to go from the independence of certain types of collections to the independence of the σ -algebras generated by these collections. To understand the result, you will need to review the definitions and theorems concerning π -systems and λ -systems. The proof uses Dynkin's π - λ theorem, named for Eugene Dynkin.

Suppose that \mathcal{A}_i is a collection of events for each i in an index set I , and that \mathcal{A}_i is a π -system for each $i \in I$. If $\{\mathcal{A}_i : i \in I\}$ is independent, then $\{\sigma(\mathcal{A}_i) : i \in I\}$ is independent.

Proof

In light of the previous result, it suffices to consider a finite set of collections. Thus, suppose that $\{\mathcal{A}_1, \mathcal{A}_2, \dots, \mathcal{A}_n\}$ is independent. Now, fix $A_i \in \mathcal{A}_i$ for $i \in \{2, 3, \dots, n\}$ and let $E = \bigcap_{i=2}^n A_i$. Let $\mathcal{L} = \{B \in \mathcal{S} : \mathbb{P}(B \cap E) = \mathbb{P}(B)\mathbb{P}(E)\}$. Trivially $S \in \mathcal{L}$ since $\mathbb{P}(S \cap E) = \mathbb{P}(E) = \mathbb{P}(S)\mathbb{P}(E)$. Next suppose that $A \in \mathcal{L}$. Then

$$\mathbb{P}(A^c \cap E) = \mathbb{P}(E) - \mathbb{P}(A \cap E) = \mathbb{P}(E) - \mathbb{P}(A)\mathbb{P}(E) = [1 - \mathbb{P}(A)]\mathbb{P}(E) = \mathbb{P}(A^c)\mathbb{P}(E) \quad (2.9.9)$$

Thus $A^c \in \mathcal{L}$. Finally, suppose that $\{A_j : j \in J\}$ is a countable collection of disjoint sets in \mathcal{L} . Then

$$\mathbb{P}\left[\left(\bigcup_{j \in J} A_j\right) \cap E\right] = \mathbb{P}\left[\bigcup_{j \in J} (A_j \cap E)\right] = \sum_{j \in J} \mathbb{P}(A_j \cap E) = \sum_{j \in J} \mathbb{P}(A_j)\mathbb{P}(E) = \mathbb{P}(E) \sum_{j \in J} \mathbb{P}(A_j) = \mathbb{P}(E)\mathbb{P}\left(\bigcup_{j \in J} A_j\right) \quad (2.9.10)$$

Therefore $\bigcup_{j \in J} A_j \in \mathcal{L}$ and so \mathcal{L} is a λ -system. Trivially $\mathcal{A}_1 \subseteq \mathcal{L}$ by the original independence assumption, so by the π - λ theorem, $\sigma(\mathcal{A}_1) \subseteq \mathcal{L}$. Thus, we have that for every $A_1 \in \sigma(\mathcal{A}_1)$ and $A_i \in \mathcal{A}_i$ for $i \in \{2, 3, \dots, n\}$,

$$\mathbb{P}\left(\bigcap_{i=1}^n A_i\right) = \prod_{i=1}^n \mathbb{P}(A_i) \quad (2.9.11)$$

Thus we have shown that $\{\sigma(\mathcal{A}_1), \mathcal{A}_2, \dots, \mathcal{A}_n\}$ is independent. Repeating the argument $n-1$ additional times, we get that $\{\sigma(\mathcal{A}_1), \sigma(\mathcal{A}_2), \dots, \sigma(\mathcal{A}_n)\}$ is independent.

The next result is a rigorous statement of the strong independence that is implied the independence of a collection of events.

Suppose that \mathcal{A} is an independent collection of events, and that $\{\mathcal{B}_j : j \in J\}$ is a partition of \mathcal{A} . That is, $\mathcal{B}_j \cap \mathcal{B}_k = \emptyset$ for $j \neq k$ and $\bigcup_{j \in J} \mathcal{B}_j = \mathcal{A}$. Then $\{\sigma(\mathcal{B}_j) : j \in J\}$ is independent.

Proof

Let \mathcal{B}_j^* denote the set of all finite intersections of sets in \mathcal{B}_j , for each $j \in J$. Then clearly \mathcal{B}_j^* is a π -system for each j , and $\{\mathcal{B}_j^* : j \in J\}$ is independent. By the previous theorem, $\{\sigma(\mathcal{B}_j^*) : j \in J\}$ is independent. But clearly $\sigma(\mathcal{B}_j^*) = \sigma(\mathcal{B}_j)$ for $j \in J$.

Let's bring the result down to earth. Suppose that A, B, C, D are independent events. In our elementary discussion of independence, you were asked to show, for example, that $A \cup B^c$ and $C^c \cup D^c$ are independent. This is a consequence of the much stronger statement that the σ -algebras $\sigma\{A, B\}$ and $\sigma\{C, D\}$ are independent.

Exchangeability

As usual, suppose that $(S, \mathcal{S}, \mathbb{P})$ is a probability space corresponding to a random experiment. Roughly speaking, a sequence of events or a sequence of random variables is *exchangeable* if the probability law that governs the sequence is unchanged when the order of the events or variables is changed. Exchangeable variables arise naturally in sampling experiments and many other settings, and are a natural generalization of a sequence of independent, identically distributed (IID) variables. Conversely, it turns out that any exchangeable sequence of variables can be constructed from an IID sequence. First we give the definition for events:

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ is a collection of events, where I is a nonempty index set. Then \mathcal{A} is *exchangeable* if the probability of the intersection of a finite number of the events depends only on the number of events. That is, if J and K are finite subsets of I and $\#(J) = \#(K)$ then

$$\mathbb{P}\left(\bigcap_{j \in J} A_j\right) = \mathbb{P}\left(\bigcap_{k \in K} A_k\right) \quad (2.9.12)$$

Exchangeability has the same basic inheritance property that we have seen before.

Suppose that \mathcal{A} is a collection of events.

1. If \mathcal{A} is exchangeable then \mathcal{B} is exchangeable for every $\mathcal{B} \subseteq \mathcal{A}$.
2. Conversely, if \mathcal{B} is exchangeable for every finite $\mathcal{B} \subseteq \mathcal{A}$ then \mathcal{A} is exchangeable.

For a collection of exchangeable events, the inclusion exclusion law for the probability of a union is much simpler than the general version.

Suppose that $\{A_1, A_2, \dots, A_n\}$ is an exchangeable collection of events. For $J \subseteq \{1, 2, \dots, n\}$ with $\#(J) = k$, let $p_k = \mathbb{P}\left(\bigcap_{j \in J} A_j\right)$. Then

$$\mathbb{P}\left(\bigcup_{i=1}^n A_i\right) = \sum_{k=1}^n (-1)^{k-1} \binom{n}{k} p_k \quad (2.9.13)$$

Proof

The inclusion-exclusion rule gives

$$\mathbb{P}\left(\bigcup_{i \in I} A_i\right) = \sum_{k=1}^n (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mathbb{P}\left(\bigcap_{j \in J} A_j\right) \quad (2.9.14)$$

But $p_k = \mathbb{P}\left(\bigcap_{j \in J} A_j\right)$ for every $J \subseteq \{1, 2, \dots, n\}$ with $\#(J) = k$, and there are $\binom{n}{k}$ such subsets.

The concept of exchangeability can be extended to random variables in the natural way. Suppose that (T, \mathcal{T}) is a measurable space.

Suppose that \mathcal{A} is a collection of random variables, each taking values in T . The collection \mathcal{A} is *exchangeable* if for any $\{X_1, X_2, \dots, X_n\} \subseteq \mathcal{A}$, the distribution of the random vector (X_1, X_2, \dots, X_n) depends only on n .

Thus, the distribution of the random vector is unchanged if the coordinates are permuted. Once again, exchangeability has the same basic inheritance property as a collection of independent variables.

Suppose that \mathcal{A} is a collection of random variables, each taking values in T .

1. If \mathcal{A} is exchangeable then \mathcal{B} is exchangeable for every $\mathcal{B} \subseteq \mathcal{A}$.
2. Conversely, if \mathcal{B} is exchangeable for every finite $\mathcal{B} \subseteq \mathcal{A}$ then \mathcal{A} is exchangeable.

Suppose that \mathcal{A} is a collection of random variables, each taking values in T , and that \mathcal{A} is exchangeable. Then trivially the variables are identically distributed: if $X, Y \in \mathcal{A}$ and $A \in \mathcal{T}$, then $\mathbb{P}(X \in A) = \mathbb{P}(Y \in A)$. Also, the definition of exchangeable variables subsumes the definition for events:

Suppose that \mathcal{A} is a collection of events, and let $\mathcal{B} = \{\mathbf{1}_A : A \in \mathcal{A}\}$ denote the corresponding collection of indicator random variables. Then \mathcal{A} is exchangeable if and only if \mathcal{B} is exchangeable.

Tail Events and Variables

Suppose again that we have a random experiment modeled by a probability space $(S, \mathcal{S}, \mathbb{P})$.

Suppose that (X_1, X_2, \dots) be a sequence of random variables. The *tail sigma algebra* of the sequence is

$$\mathcal{T} = \bigcap_{n=1}^{\infty} \sigma\{X_n, X_{n+1}, \dots\} \quad (2.9.15)$$

1. An event $B \in \mathcal{T}$ is a *tail event* for the sequence.
2. A random variable Y that is measurable with respect to \mathcal{T} is a *tail random variable* for the sequence.

Informally, a tail event (random variable) is an event (random variable) that can be defined in terms of $\{X_n, X_{n+1}, \dots\}$ for each $n \in \mathbb{N}_+$. The tail sigma algebra for a sequence of events (A_1, A_2, \dots) is defined analogously (or simply let $X_k = \mathbf{1}(A_k)$, the indicator variable of A , for each k). For the following results, you may need to review some of the definitions in the section on Convergence.

Suppose that (A_1, A_2, \dots) is a sequence of events.

1. If the sequence is increasing then $\lim_{n \rightarrow \infty} A_n = \bigcup_{n=1}^{\infty} A_n$ is a tail event of the sequence.
2. If the sequence is decreasing then $\lim_{n \rightarrow \infty} A_n = \bigcap_{n=1}^{\infty} A_n$ is a tail event of the sequence.

Proof

1. If the sequence is increasing then $\bigcup_{n=1}^{\infty} A_n = \bigcup_{n=k}^{\infty} A_n \in \sigma\{A_k, A_{k+1}, \dots\}$ for every $k \in \mathbb{N}_+$.
2. If the sequence is decreasing then $\bigcap_{n=1}^{\infty} A_n = \bigcap_{n=k}^{\infty} A_n \in \sigma\{A_k, A_{k+1}, \dots\}$ for every $k \in \mathbb{N}_+$.

Suppose again that (A_1, A_2, \dots) is a sequence of events. Each of the following is a tail event of the sequence:

1. $\limsup_{n \rightarrow \infty} A_n = \bigcap_{n=1}^{\infty} \bigcup_{i=n}^{\infty} A_i$
2. $\liminf_{n \rightarrow \infty} A_n = \bigcup_{n=1}^{\infty} \bigcap_{i=n}^{\infty} A_i$

Proof

1. The events $\bigcup_{i=n}^{\infty} A_i$ are decreasing in n and hence $\limsup_{n \rightarrow \infty} A_n = \lim_{n \rightarrow \infty} \bigcup_{i=n}^{\infty} A_i \in \mathcal{T}$ by the previous result.
2. The events $\bigcap_{i=n}^{\infty} A_i$ are increasing in n and hence $\liminf_{n \rightarrow \infty} A_n = \lim_{n \rightarrow \infty} \bigcap_{i=n}^{\infty} A_i \in \mathcal{T}$ by the previous result.

Suppose that $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of real-valued random variables.

1. $\{X_n \text{ converges as } n \rightarrow \infty\}$ is a tail event for \mathbf{X} .
2. $\liminf_{n \rightarrow \infty} X_n$ is a tail random variable for \mathbf{X} .
3. $\limsup_{n \rightarrow \infty} X_n$ is a tail random variable for \mathbf{X} .

Proof

1. The Cauchy criterion for convergence (named for Augustin Cauchy of course) states that X_n converges as $n \rightarrow \infty$ if and only if for every $\epsilon > 0$ there exists $N \in \mathbb{N}_+$ (depending on ϵ) such that if $m, n \geq N$ then $|X_n - X_m| < \epsilon$. In this criterion, we can without loss of generality take ϵ to be rational, and for a given $k \in \mathbb{N}_+$ we can insist that $m, n \geq k$. With these restrictions, the Cauchy criterion is a countable intersection of events, each of which is in $\sigma\{X_k, X_{k+1}, \dots\}$.
2. Recall that $\liminf_{n \rightarrow \infty} X_n = \lim_{n \rightarrow \infty} \inf\{X_k : k \geq n\}$.
3. Similarly, recall that $\limsup_{n \rightarrow \infty} X_n = \lim_{n \rightarrow \infty} \sup\{X_k : k \geq n\}$.

The random variable in part (b) may take the value $-\infty$, and the random variable in (c) may take the value ∞ . From parts (b) and (c) together, note that if $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ on the sample space \mathcal{S} , then X_∞ is a tail random variable for \mathbf{X} .

There are a number of *zero-one laws* in probability. These are theorems that give conditions under which an event will be essentially deterministic; that is, have probability 0 or probability 1. Interestingly, it can sometimes be difficult to determine which of these extremes is actually the case. The following result is the *Kolmogorov zero-one law*, named for Andrey Kolmogorov. It states that an event in the tail σ -algebra of an *independent* sequence will have probability 0 or 1.

Suppose that $\mathbf{X} = (X_1, X_2, \dots)$ is an independent sequence of random variables

1. If B is a tail event for \mathbf{X} then $\mathbb{P}(B) = 0$ or $\mathbb{P}(B) = 1$.
2. If Y is a real-valued tail random variable for \mathbf{X} then Y is constant with probability 1.

Proof

1. By definition $B \in \sigma\{X_{n+1}, X_{n+2}, \dots\}$ for each $n \in \mathbb{N}_+$, and hence $\{X_1, X_2, \dots, X_n, \mathbf{1}_B\}$ is an independent set of random variables. Thus $\{X_1, X_2, \dots, \mathbf{1}_B\}$ is an independent set of random variables. But $B \in \sigma\{X_1, X_2, \dots\}$, so it follows that the event B is independent of itself. Therefore $\mathbb{P}(B) = 0$ or $\mathbb{P}(B) = 1$.

2. The function $y \mapsto \mathbb{P}(Y \leq y)$ on \mathbb{R} is the (cumulative) distribution function of Y . This function is clearly increasing. Moreover, simple applications of the continuity theorems show that it is right continuous and that $\mathbb{P}(Y \leq y) \rightarrow 0$ as $y \rightarrow -\infty$ and $\mathbb{P}(Y \leq y) \rightarrow 1$ as $y \rightarrow \infty$. (Explicit proofs are given in the section on distribution functions in the chapter on Distributions.) But since Y is a tail random variable, $\{Y \leq y\}$ is a tail event and hence $\mathbb{P}(Y \leq y) \in \{0, 1\}$ for each $y \in \mathbb{R}$. It follows that there exists $c \in \mathbb{R}$ such that $\mathbb{P}(Y \leq y) = 0$ for $y < c$ and $\mathbb{P}(Y \leq y) = 1$ for $y \geq c$. Hence $\mathbb{P}(Y = c) = 1$.

From the Komogorov zero-one law and the [result above](#), note that if (A_1, A_2, \dots) is a sequence of independent events, then $\limsup_{n \rightarrow \infty} A_n$ must have probability 0 or 1. The Borel-Cantelli lemmas give conditions for which of these is correct:

Suppose that (A_1, A_2, \dots) is a sequence of independent events.

1. If $\sum_{i=1}^{\infty} \mathbb{P}(A_i) < \infty$ then $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = 0$.
2. If $\sum_{i=1}^{\infty} \mathbb{P}(A_i) = \infty$ then $\mathbb{P}(\limsup_{n \rightarrow \infty} A_n) = 1$.

Another proof of the Kolmogorov zero-one law will be given using the martingale convergence theorem.

Examples and Exercises

As always, be sure to try the computational exercises and proofs yourself before reading the answers and proofs in the text.

Counterexamples

Equal probability certainly does not imply equivalent events.

Consider the simple experiment of tossing a fair coin. The event that the coin lands heads and the event that the coin lands tails have the same probability, but are not equivalent.

Proof

Let S denote the sample space, and H the event of heads, so that H^c is the event of tails. Since the coin is fair, $\mathbb{P}(H) = \mathbb{P}(H^c) = \frac{1}{2}$. But $H \triangle H^c = S$, so $\mathbb{P}(H \triangle H^c) = 1$, so H and H^c are as far from equivalent as possible.

Similarly, equivalent distributions does not imply equivalent random variables.

Consider the experiment of rolling a standard, fair die. Let X denote the score and $Y = 7 - X$. Then X and Y have the same distribution but are not equivalent.

Proof

Since the die is fair, X is uniformly distributed on $S = \{1, 2, 3, 4, 5, 6\}$. Also $\mathbb{P}(Y = k) = \mathbb{P}(X = 7 - k) = \frac{1}{6}$ for $k \in S$, so Y also has the uniform distribution on S . But $\mathbb{P}(X = Y) = \mathbb{P}\left(X = \frac{7}{2}\right) = 0$, so X and Y are as far from equivalent as possible.

Consider the experiment of rolling two standard, fair dice and recording the sequence of scores (X, Y) . Then X and Y are independent and have the same distribution, but are not equivalent.

Proof

Since the dice are fair, (X, Y) has the uniform distribution on $\{1, 2, 3, 4, 5, 6\}^2$. Equivalently, X and Y are independent, and each has the uniform distribution on $\{1, 2, 3, 4, 5, 6\}$. But $\mathbb{P}(X = Y) = \frac{1}{6}$, so X and Y are not equivalent.

2.10: Stochastic Processes

Introduction

This section requires measure theory, so you may need to review the advanced sections in the chapter on Foundations and in this chapter. In particular, recall that a set E almost always comes with a σ -algebra \mathcal{E} of admissible subsets, so that (E, \mathcal{E}) is a measurable space. Usually in fact, E has a topology and \mathcal{E} is the corresponding Borel σ -algebra, that is, the σ -algebra generated by the topology. If E is countable, we almost always take \mathcal{E} to be the collection of all subsets of E , and in this case (E, \mathcal{E}) is a *discrete space*. The other common case is when E is an uncountable measurable subset of \mathbb{R}^n for some $n \in \mathbb{N}$, in which case \mathcal{E} is the collection of measurable subsets of E . If $(E_1, \mathcal{E}_1), (E_2, \mathcal{E}_2), \dots, (E_n, \mathcal{E}_n)$ are measurable spaces for some $n \in \mathbb{N}_+$, then the Cartesian product $E_1 \times E_2 \times \dots \times E_n$ is given the product σ -algebra $\mathcal{E}_1 \otimes \mathcal{E}_2 \otimes \dots \otimes \mathcal{E}_n$. As a special case, the Cartesian power E^n is given the corresponding power σ -algebra \mathcal{E}^n .

With these preliminary remarks out of the way, suppose that $(\Omega, \mathcal{F}, \mathbb{P})$ is a probability space, so that Ω is the set of outcomes, \mathcal{F} the σ -algebra of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . Suppose also that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces. Here is our main definition:

A *random process* or *stochastic process* on $(\Omega, \mathcal{F}, \mathbb{P})$ with *state space* (S, \mathcal{S}) and *index set* T is a collection of random variables $\mathbf{X} = \{X_t : t \in T\}$ such that X_t takes values in S for each $t \in T$.

Sometimes it's notationally convenient to write $X(t)$ instead of X_t for $t \in T$. Often $T = \mathbb{N}$ or $T = [0, \infty)$ and the elements of T are interpreted as *points in time* (discrete time in the first case and continuous time in the second). So then $X_t \in S$ is the *state* of the random process at *time* $t \in T$, and the index space (T, \mathcal{T}) becomes the *time space*.

Since X_t is itself a function from Ω into S , it follows that ultimately, a stochastic process is a function from $\Omega \times T$ into S . Stated another way, $t \mapsto X_t$ is a *random function* on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$. To make this precise, recall that S^T is the notation sometimes used for the collection of functions from T into S . Recall also that a natural σ -algebra used for S^T is the one generated by sets of the form

$$\{f \in S^T : f(t) \in A_t \text{ for all } t \in T\}, \text{ where } A_t \in \mathcal{S} \text{ for every } t \in T \text{ and } A_t = S \text{ for all but finitely many } t \in T \quad (2.10.1)$$

This σ -algebra, denoted \mathcal{S}^T , generalizes the ordinary power σ -algebra \mathcal{S}^n mentioned in the opening paragraph and will be important in the discussion of existence below.

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with state space (S, \mathcal{S}) and index set T . Then the mapping that takes ω into the function $t \mapsto X_t(\omega)$ is measurable with respect to (Ω, \mathcal{F}) and (S^T, \mathcal{S}^T) .

Proof

Recall that a mapping with values in S^T is measurable if and only if each of its “coordinate functions” is measurable. In the present context that means that we must show that the function X_t is measurable with respect to (Ω, \mathcal{F}) and (S, \mathcal{S}) for each $t \in T$. But of course, that follows from the very meaning of the term *random variable*.

For $\omega \in \Omega$, the function $t \mapsto X_t(\omega)$ is known as a *sample path* of the process. So S^T , the set of functions from T into S , can be thought of as a *set of outcomes* of the stochastic process \mathbf{X} , a point we will return to in our discussion of existence below.

As noted in the proof of the last theorem, X_t is a measurable function from Ω into S for each $t \in T$, by the very meaning of the term *random variable*. But it does not follow in general that $(\omega, t) \mapsto X_t(\omega)$ is measurable as a function from $\Omega \times T$ into S . In fact, the σ -algebra on T has played no role in our discussion so far. Informally, a statement about X_t for a *fixed* $t \in T$ or even a statement about X_t for countably many $t \in T$ defines an event. But it does not follow that a statement about X_t for uncountably many $t \in T$ defines an event. We often want to make such statements, so the following definition is inevitable:

A stochastic process $\mathbf{X} = \{X_t : t \in T\}$ defined on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and with index space (T, \mathcal{T}) and state space (S, \mathcal{S}) is *measurable* if $(\omega, t) \mapsto X_t(\omega)$ is a measurable function from $\Omega \times T$ into S .

Every stochastic process indexed by a countable set T is measurable, so the definition is only important when T is uncountable, and in particular for $T = [0, \infty)$.

Equivalent Processes

Our next goal is to study different ways that two stochastic processes, with the same state and index spaces, can be “equivalent”. We will assume that the diagonal $D = \{(x, x) : x \in S\} \in \mathcal{S}^2$, an assumption that almost always holds in applications, and in particular for the discrete and Euclidean spaces that are most important to us. Sufficient conditions are that \mathcal{S} have a sub σ -algebra that is countably generated and contains all of the singleton sets, properties that hold for the Borel σ -algebra when the topology on S is locally compact, Hausdorff, and has a countable base.

First, we often feel that we understand a random process $\mathbf{X} = \{X_t : t \in T\}$ well if we know the *finite dimensional distributions*, that is, if we know the distribution of $(X_{t_1}, X_{t_2}, \dots, X_{t_n})$ for every choice of $n \in \mathbb{N}_+$ and $(t_1, t_2, \dots, t_n) \in T^n$. Thus, we can compute $\mathbb{P}[(X_{t_1}, X_{t_2}, \dots, X_{t_n}) \in A]$ for

every $n \in \mathbb{N}_+$, $(t_1, t_2, \dots, t_n) \in T^n$, and $A \in \mathcal{S}^n$. Using various rules of probability, we can compute the probabilities of many events involving infinitely many values of the index parameter t as well. With this idea in mind, we have the following definition:

Random processes $\mathbf{X} = \{X_t : t \in T\}$ and $\mathbf{Y} = \{Y_t : t \in T\}$ with state space (S, \mathcal{S}) and index set T are *equivalent in distribution* if they have the same finite dimensional distributions. This defines an equivalence relation on the collection of stochastic processes with this state space and index set. That is, if \mathbf{X} , \mathbf{Y} , and \mathbf{Z} are such processes then

1. \mathbf{X} is equivalent in distribution to \mathbf{X} (the *reflexive property*)
2. If \mathbf{X} is equivalent in distribution to \mathbf{Y} then \mathbf{Y} is equivalent in distribution to \mathbf{X} (the *symmetric property*)
3. If \mathbf{X} is equivalent in distribution to \mathbf{Y} and \mathbf{Y} is equivalent in distribution to \mathbf{Z} then \mathbf{X} is equivalent in distribution to \mathbf{Z} (the *transitive property*)

Note that since only the finite-dimensional distributions of the processes \mathbf{X} and \mathbf{Y} are involved in the definition, the processes need not be defined on the same probability space. Thus, *equivalence in distribution* partitions the collection of all random processes with a given state space and index set into mutually disjoint equivalence classes. But of course, we already know that two random variables can have the same *distribution* but be very different as variables (functions on the sample space). Clearly, the same statement applies to random processes.

Suppose that $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of Bernoulli trials with success parameter $p = \frac{1}{2}$. Let $Y_n = 1 - X_n$ for $n \in \mathbb{N}_+$. Then $\mathbf{Y} = (Y_1, Y_2, \dots)$ is equivalent in distribution to \mathbf{X} but

$$\mathbb{P}(X_n \neq Y_n \text{ for every } n \in \mathbb{N}_+) = 1 \quad (2.10.2)$$

Proof

By the meaning of *Bernoulli trials*, \mathbf{X} is a sequence of independent indicator random variables with $\mathbb{P}(X_n = 1) = \frac{1}{2}$ for each $n \in \mathbb{N}_+$. It follows that \mathbf{Y} is also a Bernoulli trials sequence with success parameter $\frac{1}{2}$, so \mathbf{X} and \mathbf{Y} are equivalent in distribution. Also, of course, the state set is $\{0, 1\}$ and $Y_n = 1$ if and only if $X_n = 0$.

Motivated by this example, let's look at another, stronger way that random processes can be equivalent. First recall that random variables X and Y on $(\Omega, \mathcal{F}, \mathbb{P})$, with values in S , are *equivalent* if $\mathbb{P}(X = Y) = 1$.

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ and $\mathbf{Y} = \{Y_t : t \in T\}$ are stochastic processes defined on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and both with state space (S, \mathcal{S}) and index set T . Then \mathbf{Y} is a *version* of \mathbf{X} if Y_t is equivalent to X_t (so that $\mathbb{P}(X_t = Y_t) = 1$) for every $t \in T$. This defines an equivalence relation on the collection of stochastic processes on the same probability space and with the same state space and index set. That is, if \mathbf{X} , \mathbf{Y} , and \mathbf{Z} are such processes then

1. \mathbf{X} is a version of \mathbf{X} (the *reflexive property*)
2. If \mathbf{X} is a version of \mathbf{Y} then \mathbf{Y} is a version of \mathbf{X} (the *symmetric property*)
3. If \mathbf{X} is a version of \mathbf{Y} and \mathbf{Y} is of \mathbf{Z} then \mathbf{X} is a version of \mathbf{Z} (the *transitive property*)

Proof

Note that (X_t, Y_t) is a random variable with values in S^2 (and so the function $\omega \mapsto (X_t(\omega), Y_t(\omega))$ is measurable). The event $\{X_t = Y_t\}$ is the inverse image of the diagonal $D \in \mathcal{S}^2$ under this mapping, and so the definition makes sense.

So the *version of* relation partitions the collection of stochastic processes on a given probability space and with a given state space and index set into mutually disjoint equivalence classes.

Suppose again that $\mathbf{X} = \{X_t : t \in T\}$ and $\mathbf{Y} = \{Y_t : t \in T\}$ are random processes on $(\Omega, \mathcal{F}, \mathbb{P})$ with state space (S, \mathcal{S}) and index set T . If \mathbf{Y} is a version of \mathbf{X} then \mathbf{Y} and \mathbf{X} are equivalent in distribution.

Proof

Suppose that $(t_1, t_2, \dots, t_n) \in T^n$ and that $A \in \mathcal{S}^n$. Recall that the intersection of a finite (or even countably infinite) collection of events with probability 1 still has probability 1. Hence

$$\mathbb{P}[(X_{t_1}, X_{t_2}, \dots, X_{t_n}) \in A] = \mathbb{P}[(X_{t_1}, X_{t_2}, \dots, X_{t_n}) \in A, X_{t_1} = Y_{t_1}, X_{t_2} = Y_{t_2}, \dots, X_{t_n} = Y_{t_n}] \quad (2.10.3)$$

$$= \mathbb{P}[(Y_{t_1}, Y_{t_2}, \dots, Y_{t_n}) \in A, X_{t_1} = Y_{t_1}, X_{t_2} = Y_{t_2}, \dots, X_{t_n} = Y_{t_n}] = \mathbb{P}[(Y_{t_1}, Y_{t_2}, \dots, Y_{t_n}) \in A] \quad (2.10.4)$$

As noted in the proof, a countable intersection of events with probability 1 still has probability 1. Hence if T is countable and random processes \mathbf{X} is a version of \mathbf{Y} then

$$\mathbb{P}(X_t = Y_t \text{ for all } t \in T) = 1 \quad (2.10.5)$$

so \mathbf{X} and \mathbf{Y} really are essentially the same random process. But when T is uncountable the result in the displayed equation may not be true, and \mathbf{X} and \mathbf{Y} may be very different as random functions on T . Here is a simple example:

Suppose that $\Omega = T = [0, \infty)$, $\mathcal{F} = \mathcal{S}$ is the σ -algebra of Borel measurable subsets of $[0, \infty)$, and \mathbb{P} is any continuous probability measure on (Ω, \mathcal{F}) . Let $S = \{0, 1\}$ (with all subsets measurable, of course). For $t \in T$ and $\omega \in \Omega$, define $X_t(\omega) = \mathbf{1}_t(\omega)$ and $Y_t(\omega) = 0$. Then $\mathbf{X} = \{X_t : t \in T\}$ is a version of $\mathbf{Y} = \{Y_t : t \in T\}$, but $\mathbb{P}(X_t = Y_t \text{ for all } t \in T) = 0$.

Proof

For $t \in [0, \infty)$, $\mathbb{P}(X_t \neq Y_t) = \mathbb{P}\{t\} = 0$ since P is a continuous measure. But $\{\omega \in \Omega : X_t(\omega) = Y_t(\omega) \text{ for all } t \in T\} = \emptyset$.

Motivated by this example, we have our strongest form of equivalence:

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ and $\mathbf{Y} = \{Y_t : t \in T\}$ are measurable random processes on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and with state space (S, \mathcal{S}) and index space (T, \mathcal{T}) . Then \mathbf{X} is *indistinguishable from* \mathbf{Y} if $\mathbb{P}(X_t = Y_t \text{ for all } t \in T) = 1$. This defines an equivalence relation on the collection of measurable stochastic processes defined on the same probability space and with the same state and index spaces. That is, if \mathbf{X} , \mathbf{Y} , and \mathbf{Z} are such processes then

1. \mathbf{X} is indistinguishable from \mathbf{X} (the *reflexive property*)
2. If \mathbf{X} is indistinguishable from \mathbf{Y} then \mathbf{Y} is indistinguishable from \mathbf{X} (the *symmetric property*)
3. If \mathbf{X} is indistinguishable from \mathbf{Y} and \mathbf{Y} is indistinguishable from \mathbf{Z} then \mathbf{X} is indistinguishable from \mathbf{Z} (the *transitive property*)

Details

The measurability requirement for the stochastic processes is needed to ensure that $\{X_t = Y_t \text{ for all } t \in T\}$ is a valid event. To see this, note that $(\omega, t) \mapsto (X_t(\omega), Y_t(\omega))$ is measurable, as a function from $\Omega \times T$ into S^2 . As before, let $D = \{(x, x) : x \in S\}$ denote the diagonal. Then $D^c \in \mathcal{S}^2$ and the inverse image of D^c under our mapping is

$$\{(\omega, t) \in \Omega \times T : X_t(\omega) \neq Y_t(\omega)\} \in \mathcal{F} \otimes \mathcal{T} \quad (2.10.6)$$

The projection of this set onto Ω

$$\{\omega \in \Omega : X_t(\omega) \neq Y_t(\omega) \text{ for some } t \in T\} \in \mathcal{F} \quad (2.10.7)$$

since the projection of a measurable set in the product space is also measurable. Hence the complementary event

$$\{\omega \in \Omega : X_t(\omega) = Y_t(\omega) \text{ for all } t \in T\} \in \mathcal{F} \quad (2.10.8)$$

So the *indistinguishable from* relation partitions the collection of measurable stochastic processes on a given probability space and with given state space and index space into mutually disjoint equivalence classes. Trivially, if \mathbf{X} is indistinguishable from \mathbf{Y} , then \mathbf{X} is a version of \mathbf{Y} . As noted above, when T is countable, the converse is also true, but not, as our previous example shows, when T is uncountable. So to summarize, *indistinguishable from* implies *version of* implies *equivalent in distribution*, but none of the converse implications hold in general.

The Kolmogorov Construction

In applications, a stochastic process is often modeled by giving various distributional properties that the process should satisfy. So the basic existence problem is to construct a process that has these properties. More specifically, how can we construct random processes with specified finite dimensional distributions? Let's start with the simplest case, one that we have seen several times before, and build up from there. Our simplest case is to construct a single random variable with a specified distribution.

Suppose that (S, \mathcal{S}, P) is a probability space. Then there exists a random variable X on probability space $(\Omega, \mathcal{F}, \mathbb{P})$ such that X takes values in S and has distribution P .

Proof

The proof is utterly trivial. Let $(\Omega, \mathcal{F}, \mathbb{P}) = (S, \mathcal{S}, P)$ and define $X : \Omega \rightarrow S$ by $X(\omega) = \omega$, so that X is the identity function. Then $\{X \in A\} = A$ and so $\mathbb{P}(X \in A) = P(A)$ for $A \in \mathcal{S}$.

In spite of its triviality the last result contains the seeds of everything else we will do in this discussion. Next, let's see how to construct a sequence of independent random variables with specified distributions.

Suppose that P_i is a probability measure on the measurable space (S, \mathcal{S}) for $i \in \mathbb{N}_+$. Then there exists an independent sequence of random variables (X_1, X_2, \dots) on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ such that X_i takes values in S and has distribution P_i for $i \in \mathbb{N}_+$.

Proof

Let $\Omega = S^\infty = S \times S \times \dots$. Next let $\mathcal{F} = \mathcal{S}^\infty$, the corresponding product σ -algebra. Recall that this is the σ -algebra generated by sets of the form

$$A_1 \times A_2 \times \dots \text{ where } A_i \in \mathcal{S} \text{ for each } i \in I \text{ and } A_i = S \text{ for all but finitely many } i \in I \quad (2.10.9)$$

Finally, let $\mathbb{P} = P_1 \otimes P_2 \otimes \dots$, the corresponding product measure on (Ω, \mathcal{F}) . Recall that this is the unique probability measure that satisfies

$$\mathbb{P}(A_1 \times A_2 \times \dots) = P_1(A_1)P_2(A_2) \dots \quad (2.10.10)$$

where $A_1 \times A_2 \times \dots$ is a set of the type in the first displayed equation. Now define X_i on Ω by $X_i(\omega_1, \omega_2, \dots) = \omega_i$, for $i \in \mathbb{N}_+$, so that X_i is simply the coordinate function for index i . If $A_1 \times A_2 \times \dots$ is a set of the type in the first displayed equation then

$$\{X_1 \in A_1, X_2 \in A_2, \dots\} = A_1 \times A_2 \times \dots \quad (2.10.11)$$

and so by the definition of the product measure,

$$\mathbb{P}(X_1 \in A_1, X_2 \in A_2, \dots) = P_1(A_1)P_2(A_2) \dots \quad (2.10.12)$$

It follows that (X_1, X_2, \dots) is a sequence of independent variables and that X_i has distribution P_i for $i \in \mathbb{N}$.

If you looked at the proof of the last two results you might notice that the last result can be viewed as a special case of the one before, since $\mathbf{X} = (X_1, X_2, \dots)$ is simply the identity function on $\Omega = S^\infty$. The important step is the existence of the product measure \mathbb{P} on (Ω, \mathcal{F}) .

The full generalization of these results is known as the *Kolmogorov existence theorem* (named for Andrei Kolmogorov). We start with the state space (S, \mathcal{S}) and the index set T . The theorem states that if we specify the finite dimensional distributions in a consistent way, then there exists a stochastic process defined on a suitable probability space that has the given finite dimensional distributions. The consistency condition is a bit clunky to state in full generality, but the basic idea is very easy to understand. Suppose that s and t are distinct elements in T and that we specify the distribution (probability measure) P_s of X_s , P_t of X_t , $P_{s,t}$ of (X_s, X_t) , and $P_{t,s}$ of (X_t, X_s) . Then clearly we must specify these so that

$$P_s(A) = P_{s,t}(A \times S), \quad P_t(B) = P_{t,s}(S \times B) \quad (2.10.13)$$

For all $A, B \in \mathcal{S}$. Clearly we also must have $P_{s,t}(C) = P_{t,s}(C')$ for all measurable $C \in \mathcal{S}^2$, where $C' = \{(y, x) : (x, y) \in C\}$.

To state the consistency conditions in general, we need some notation. For $n \in \mathbb{N}_+$, let $T^{(n)} \subset T^n$ denote the set of n -tuples of distinct elements of T , and let $\mathbf{T} = \bigcup_{n=1}^{\infty} T^{(n)}$ denote the set of all finite sequences of distinct elements of T . If $n \in \mathbb{N}_+$, $\mathbf{t} = (t_1, t_2, \dots, t_n) \in T^{(n)}$ and π is a permutation of $\{1, 2, \dots, n\}$, let $\mathbf{t}\pi$ denote the element of $T^{(n)}$ with coordinates $(\mathbf{t}\pi)_i = t_{\pi(i)}$. That is, we permute the coordinates of \mathbf{t} according to π . If $C \in \mathcal{S}^n$, let

$$\pi C = \{(x_1, x_2, \dots, x_n) \in S^n : (x_{\pi(1)}, x_{\pi(2)}, \dots, x_{\pi(n)}) \in C\} \in \mathcal{S}^n \quad (2.10.14)$$

finally, if $n > 1$, let \mathbf{t}_- denote the vector $(t_1, t_2, \dots, t_{n-1}) \in T^{(n-1)}$

Now suppose that $P_{\mathbf{t}}$ is a probability measure on (S^n, \mathcal{S}^n) for each $n \in \mathbb{N}_+$ and $\mathbf{t} \in T^{(n)}$. The idea, of course, is that we want the collection $\mathcal{P} = \{P_{\mathbf{t}} : \mathbf{t} \in \mathbf{T}\}$ to be the finite dimensional distributions of a random process with index set T and state space (S, \mathcal{S}) . Here is the critical definition:

The collection of probability distributions \mathcal{P} relative to T and (S, \mathcal{S}) is *consistent* if

1. $P_{\mathbf{t}\pi}(C) = P_{\mathbf{t}}(\pi C)$ for every $n \in \mathbb{N}_+$, $\mathbf{t} \in T^{(n)}$, permutation π of $\{1, 2, \dots, n\}$, and measurable $C \subseteq S^n$.
2. $P_{\mathbf{t}_-}(C) = P_{\mathbf{t}}(C \times S)$ for every $n > 1$, $\mathbf{t} \in T^{(n)}$, and measurable $C \subseteq S^{n-1}$

With the proper definition of consistence, we can state the fundamental theorem.

Kolmogorov Existence Theorem. If \mathcal{P} is a consistent collection of probability distributions relative to the index set T and the state space (S, \mathcal{S}) , then there exists a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and a stochastic process $\mathbf{X} = \{X_t : t \in T\}$ on this probability space such that \mathcal{P} is the collection of finite dimensional distribution of \mathbf{X} .

Proof sketch

Let $\Omega = S^T$, the set of functions from T to S . Such functions are the *outcomes* of the stochastic process. Let $\mathcal{F} = \mathcal{S}^T$, the product σ -algebra, generated by sets of the form

$$B = \{\omega \in \Omega : \omega(t) \in A_t \text{ for all } t \in T\} \quad (2.10.15)$$

where $A_t \in \mathcal{S}$ for all $t \in T$ and $A_t = S$ for all but finitely many $t \in T$. We know how our desired probability measure \mathbb{P} should work on the sets that generate \mathcal{F} . Specifically, suppose that B is a set of the type in the displayed equation, and $A_t = S$ except for $\mathbf{t} = (t_1, t_2, \dots, t_n) \in T^{(n)}$. Then we want

$$\mathbb{P}(B) = P_{\mathbf{t}}(A_{t_1} \times A_{t_2} \times \dots \times A_{t_n}) \quad (2.10.16)$$

Basic existence and uniqueness theorems in measure theory that we discussed earlier, and the consistency of \mathcal{P} , guarantee that \mathbb{P} can be extended to a probability measure on all of \mathcal{F} . Finally, for $t \in T$ we define $X_t : \Omega \rightarrow S$ by $X_t(\omega) = \omega(t)$ for $\omega \in \Omega$, so that X_t is simply the coordinate function of index t . Thus, we have a stochastic process $\mathbf{X} = \{X_t : t \in T\}$ with state space (S, \mathcal{S}) , defined on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$, with \mathcal{P} as the collection of finite dimensional distributions.

Note that except for the more complicated notation, the construction is very similar to the one for a [sequence of independent variables](#). Again, \mathbf{X} is essentially the identity function on $\Omega = S^T$. The important and more difficult part is the construction of the probability measure \mathbb{P} on (Ω, \mathcal{F}) .

Applications

Our last discussion is a summary of the stochastic processes that are studied in this text. All are classics and are immensely important in applications.

Random processes are associated with Bernoulli trials include

1. the Bernoulli trials sequence itself
2. the sequence of binomial variables

3. the sequence of geometric variables
4. the sequence of negative binomial variables
5. the simple random walk

Construction

The Bernoulli trials sequence in (a) is a sequence of independent, identically distributed indicator random variables, and so can be constructed as in (). The random processes in (b)–(e) are constructed from the Bernoulli trials sequence.

Random process associated with the Poisson model include

1. the sequence of inter-arrival times
2. the sequence of arrival times
3. the counting process on $[0, \infty)$, both in the homogeneous and non-homogeneous cases.
4. A compound Poisson process.
5. the counting process on a general measure space

Constructions

The random process in (a) is a sequence of independent random variable with a common exponential distribution, and so can be constructed as in (). The processes in (b) and (c) can be constructed from the sequence in (a).

Random processes associated with renewal theory include

1. the sequence of inter-arrival times
2. the sequence of arrival times
3. the counting process on $[0, \infty)$

Markov chains form a very important family of random processes as do Brownian motion and related processes. We will study these in subsequent chapters.

2.11: Filtrations and Stopping Times

Introduction

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process with state space (S, \mathcal{S}) defined on an underlying probability space $(\Omega, \mathcal{F}, \mathbb{P})$. To review, Ω is the set of outcomes, \mathcal{F} the σ -algebra of events, and \mathbb{P} the probability measure on (S, \mathcal{S}) . Also S is the set of states, and \mathcal{S} the σ -algebra of admissible subsets of S . Usually, S is a topological space and \mathcal{S} the Borel σ -algebra generated by the open subsets of S . A standard set of assumptions is that the topology is locally compact, Hausdorff, and has a countable base, which we will abbreviate by *LCCB*. For the index set, we assume that either $T = \mathbb{N}$ or that $T = [0, \infty)$ and as usual in these cases, we interpret the elements of T as points of time. The set T is also given a topology, the discrete topology in the first case and the standard Euclidean topology in the second case, and then the Borel σ -algebra \mathcal{T} . So in discrete time with $T = \mathbb{N}$, $\mathcal{T} = \mathcal{P}(T)$, the power set of T , so every subset of T is measurable, as is every function from T into a another measurable space. Finally, X_t is a random variable and so by definition is measurable with respect to \mathcal{F} and \mathcal{S} for each $t \in T$. We interpret X_t is the state of some random system at time $t \in T$. Many important concepts involving \mathbf{X} are based on how the *future* behavior of the process depends on the *past* behavior, relative to a given *current* time.

For $t \in T$, let $\mathcal{F}_t = \sigma\{X_s : s \in T, s \leq t\}$, the σ -algebra of events that can be defined in terms of the process up to time t . Roughly speaking, for a given $A \in \mathcal{F}_t$, we can tell whether or not A has occurred if we are allowed to observe the process up to time t . The family of σ -algebras $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ has two critical properties: the family is increasing in $t \in T$, relative to the subset partial order, and all of the σ -algebras are sub σ -algebras of \mathcal{F} . That is for $s, t \in T$ with $s \leq t$, we have $\mathcal{F}_s \subseteq \mathcal{F}_t \subseteq \mathcal{F}$.

Filtrations

Basic Definitions

Sometimes we need σ -algebras that are a bit larger than the ones in the last paragraph. For example, there may be other random variables that we get to observe, as time goes by, besides the variables in \mathbf{X} . Sometimes, particularly in continuous time, there are technical reasons for somewhat different σ -algebras. Finally, we may want to describe how our information grows, as a family of σ -algebras, without reference to a random process. For the remainder of this section, we have a fixed measurable space (Ω, \mathcal{F}) which we again think of as a sample space, and the time space (T, \mathcal{T}) as described above.

A family of σ -algebras $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a *filtration* on (Ω, \mathcal{F}) if $s, t \in T$ and $s \leq t$ imply $\mathcal{F}_s \subseteq \mathcal{F}_t \subseteq \mathcal{F}$. The object $(\Omega, \mathcal{F}, \mathfrak{F})$ is a *filtered sample space*. If \mathbb{P} is a probability measure on (Ω, \mathcal{F}) , then $(\Omega, \mathcal{F}, \mathfrak{F}, \mathbb{P})$ is a *filtered probability space*.

So a filtration is simply an increasing family of sub- σ -algebras of \mathcal{F} , indexed by T . We think of \mathcal{F}_t as the σ -algebra of events up to time $t \in T$. The larger the σ -algebras in a filtration, the more events that are available, so the following relation on filtrations is natural.

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ and $\mathfrak{G} = \{\mathcal{G}_t : t \in T\}$ are filtrations on (Ω, \mathcal{F}) . We say that \mathfrak{F} is *coarser than* \mathfrak{G} and \mathfrak{G} is *finer than* \mathfrak{F} , and we write $\mathfrak{F} \preceq \mathfrak{G}$, if $\mathcal{F}_t \subseteq \mathcal{G}_t$ for all $t \in T$. The relation \preceq is a partial order on the collection of filtrations on (Ω, \mathcal{F}) . That is, if $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$, $\mathfrak{G} = \{\mathcal{G}_t : t \in T\}$, and $\mathfrak{H} = \{\mathcal{H}_t : t \in T\}$ are filtrations then

1. $\mathfrak{F} \preceq \mathfrak{F}$, the *reflexive property*.
2. If $\mathfrak{F} \preceq \mathfrak{G}$ and $\mathfrak{G} \preceq \mathfrak{F}$ then $\mathfrak{F} = \mathfrak{G}$, the *antisymmetric property*.
3. If $\mathfrak{F} \preceq \mathfrak{G}$ and $\mathfrak{G} \preceq \mathfrak{H}$ then $\mathfrak{F} \preceq \mathfrak{H}$, the *transitive property*.

Proof

The proof is a simple consequence of the fact that the subset relation defines a partial order.

1. $\mathcal{F}_t \subseteq \mathcal{F}_t$ for each $t \in T$ so $\mathfrak{F} \preceq \mathfrak{F}$.
2. If $\mathfrak{F} \preceq \mathfrak{G}$ and $\mathfrak{G} \preceq \mathfrak{F}$ then $\mathcal{F}_t \subseteq \mathcal{G}_t$ and $\mathcal{G}_t \subseteq \mathcal{F}_t$ for each $t \in T$. Hence $\mathcal{F}_t = \mathcal{G}_t$ for each $t \in T$ and so $\mathfrak{F} = \mathfrak{G}$.
3. If $\mathfrak{F} \preceq \mathfrak{G}$ and $\mathfrak{G} \preceq \mathfrak{H}$ then $\mathcal{F}_t \subseteq \mathcal{G}_t$ and $\mathcal{G}_t \subseteq \mathcal{H}_t$ for each $t \in T$. Hence $\mathcal{F}_t \subseteq \mathcal{H}_t$ for each $t \in T$ and so $\mathfrak{F} \preceq \mathfrak{H}$.

So the coarsest filtration on (Ω, \mathcal{F}) is the one where $\mathcal{F}_t = \{\Omega, \emptyset\}$ for every $t \in T$ while the finest filtration is the one where $\mathcal{F}_t = \mathcal{F}$ for every $t \in T$. In the first case, we gain no information as time evolves, and in the second case, we have complete information from the beginning of time. Usually neither of these is realistic.

It's also natural to consider the σ -algebra that encodes our information over *all* time.

For a filtration $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ on (Ω, \mathcal{F}) , define $\mathcal{F}_\infty = \sigma(\bigcup\{\mathcal{F}_t : t \in T\})$. Then

1. $\mathcal{F}_\infty = \sigma(\bigcup\{\mathcal{F}_t : t \in T, t \geq s\})$ for $s \in T$.
2. $\mathcal{F}_t \subseteq \mathcal{F}_\infty$ for $t \in T$.

Proof

These results follow since the σ -algebras in a filtration are increasing in time.

Of course, it may be the case that $\mathcal{F}_\infty = \mathcal{F}$, but not necessarily. Recall that the intersection of a collection of σ -algebras on (Ω, \mathcal{F}) is another σ -algebra. We can use this to create new filtrations from a collection of given filtrations.

Suppose that $\mathcal{F}_i = \{\mathcal{F}_t^i : t \in T\}$ is a filtration on (Ω, \mathcal{F}) for each i in a nonempty index set I . Then $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ where $\mathcal{F}_t = \bigcap_{i \in I} \mathcal{F}_t^i$ for $t \in T$ is also a filtration on (Ω, \mathcal{F}) . This filtration is sometimes denoted $\mathcal{F} = \bigwedge_{i \in I} \mathcal{F}_i$, and is the finest filtration that is coarser than \mathcal{F}_i for every $i \in I$.

Proof

Suppose $s, t \in T$ with $s \leq t$. Then $\mathcal{F}_s^i \subseteq \mathcal{F}_t^i \subseteq \mathcal{F}$ for each $i \in I$ so it follows that $\bigcap_{i \in I} \mathcal{F}_s^i \subseteq \bigcap_{i \in I} \mathcal{F}_t^i \subseteq \mathcal{F}$.

Unions of σ -algebras are not in general σ -algebras, but we can construct a new filtration from a given collection of filtrations using unions in a natural way.

Suppose again that $\mathcal{F}_i = \{\mathcal{F}_t^i : t \in T\}$ is a filtration on (Ω, \mathcal{F}) for each i in a nonempty index set I . Then $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ where $\mathcal{F}_t = \sigma(\bigcup_{i \in I} \mathcal{F}_t^i)$ for $t \in T$ is also a filtration on (Ω, \mathcal{F}) . This filtration is sometimes denoted $\mathcal{F} = \bigvee_{i \in I} \mathcal{F}_i$, and is the coarsest filtration that is finer than \mathcal{F}_i for every $i \in I$.

Proof

Suppose $s, t \in T$ with $s \leq t$. Then $\mathcal{F}_s^i \subseteq \mathcal{F}_t^i \subseteq \mathcal{F}$ for each $i \in I$ so it follows that $\bigcup_{i \in I} \mathcal{F}_s^i \subseteq \bigcup_{i \in I} \mathcal{F}_t^i \subseteq \mathcal{F}$, and hence $\sigma(\bigcup_{i \in I} \mathcal{F}_s^i) \subseteq \sigma(\bigcup_{i \in I} \mathcal{F}_t^i) \subseteq \mathcal{F}$.

Stochastic Processes

Note again that we can have a filtration without an underlying stochastic process in the background. However, we usually *do* have a stochastic process $\mathbf{X} = \{X_t : t \in T\}$, and in this case the filtration $\mathcal{F}^0 = \{\mathcal{F}_t^0 : t \in T\}$ where $\mathcal{F}_t^0 = \sigma\{X_s : s \in T, s \leq t\}$ is the *natural filtration* associated with \mathbf{X} . More generally, the following definition is appropriate.

A stochastic process $\mathbf{X} = \{X_t : t \in T\}$ on (Ω, \mathcal{F}) is *adapted* to a filtration $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ on (Ω, \mathcal{F}) if X_t is measurable with respect to \mathcal{F}_t for each $t \in T$.

Equivalently, \mathbf{X} is adapted to \mathcal{F} if \mathcal{F} is finer than \mathcal{F}^0 , the natural filtration associated with \mathbf{X} . That is, $\sigma\{X_s : s \in T, s \leq t\} \subseteq \mathcal{F}_t$ for each $t \in T$. So clearly, if \mathbf{X} is adapted to a filtration, then it is adapted to any finer filtration, and \mathcal{F}^0 is the coarsest filtration to which \mathbf{X} is adapted. The basic idea behind the definition is that if the filtration \mathcal{F} encodes our information as time goes by, then the process \mathbf{X} is observable. In discrete time, there is a related definition.

Suppose that $T = \mathbb{N}$. A stochastic process $\mathbf{X} = \{X_n : n \in \mathbb{N}\}$ is *predictable* by the filtration $\mathcal{F} = \{\mathcal{F}_n : n \in \mathbb{N}\}$ if X_{n+1} is measurable with respect to \mathcal{F}_n for all $n \in \mathbb{N}$.

Clearly if \mathbf{X} is predictable by \mathcal{F} then \mathbf{X} is adapted to \mathcal{F} . But predictable is better than adapted, in the sense that if \mathcal{F} encodes our information as time goes by, then we can look one step into the future in terms of \mathbf{X} : at time n we can determine X_{n+1} . The concept of predictability can be extended to continuous time, but the definition is much more complicated.

Note that ultimately, a stochastic process $\mathbf{X} = \{X_t : t \in T\}$ with sample space (Ω, \mathcal{F}) and state space (S, \mathcal{S}) can be viewed as a function from $\Omega \times T$ into S , so $X_t(\omega) \in S$ is the state at time $t \in T$ corresponding to the outcome $\omega \in \Omega$. By definition, $\omega \mapsto X_t(\omega)$ is measurable for each $t \in T$, but it is often necessary for the process to be jointly measurable in ω and t .

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process with sample space (Ω, \mathcal{F}) and state space (S, \mathcal{S}) . Then \mathbf{X} is *measurable* if $\mathbf{X} : \Omega \times T \rightarrow S$ is measurable with respect to $\mathcal{F} \otimes \mathcal{T}$ and \mathcal{S} .

When we have a filtration, as we usually do, there is a stronger condition that is natural. Let $T_t = \{s \in T : s \leq t\}$ for $t \in T$, and let $\mathcal{F}_t = \{A \cap T_t : A \in \mathcal{F}\}$ be the corresponding induced σ -algebra.

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process with sample space (Ω, \mathcal{F}) and state space (S, \mathcal{S}) , and that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration. Then \mathbf{X} is *progressively measurable* relative to \mathfrak{F} if $\mathbf{X} : \Omega \times T_t \rightarrow S$ is measurable with respect to $\mathcal{F}_t \otimes \mathcal{T}_t$ and \mathcal{S} for each $t \in T$.

Clearly if \mathbf{X} is progressively measurable with respect to a filtration, then it is progressively measurable with respect to any finer filtration. Of course when T is discrete, then any process \mathbf{X} is measurable, and any process \mathbf{X} adapted to \mathfrak{F} progressively measurable, so these definitions are only of interest in the case of continuous time.

Suppose again that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process with sample space (Ω, \mathcal{F}) and state space (S, \mathcal{S}) , and that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration. If \mathbf{X} is progressively measurable relative to \mathfrak{F} then

1. \mathbf{X} is measurable.
2. \mathbf{X} is adapted to \mathfrak{F} .

Proof

Suppose that \mathbf{X} is progressively measurable relative to \mathfrak{F} .

1. If $A \in \mathcal{S}$ then

$$\mathbf{X}^{-1}(A) = \{(\omega, t) \in \Omega \times T : X_t(\omega) \in A\} = \bigcup_{n=1}^{\infty} \{(\omega, t) \in \Omega \times T_n : X_t(\omega) \in A\} \quad (2.11.1)$$

By assumption, the n th term in the union is in $\mathcal{F} \otimes \mathcal{T}_n \subseteq \mathcal{F} \otimes \mathcal{T}$, so the union is in $\mathcal{F} \otimes \mathcal{T}$.

2. Suppose that $t \in T$. Then $\mathbf{X} : \Omega \times T_t \rightarrow S$ is measurable with respect to $\mathcal{F}_t \otimes \mathcal{T}_t$ and \mathcal{S} . But $X_t : \Omega \rightarrow S$ is just the cross section of this function at t and hence is measurable with respect to \mathcal{F}_t and \mathcal{S} .

When the state space is a topological space (which is usually the case), then as you might guess, there is a natural link between continuity of the sample paths and progressive measurability.

Suppose that S has an LCCB topology and that \mathcal{S} is the σ -algebra of Borel sets. Suppose also that $\mathbf{X} = \{X_t : t \in [0, \infty)\}$ is right continuous. Then \mathbf{X} is progressively measurable relative to the natural filtration \mathfrak{F}^0 .

So if \mathbf{X} is right continuous, then \mathbf{X} is progressively measurable with respect to any filtration to which \mathbf{X} is adapted. Recall that in the previous section, we studied different ways that two stochastic processes can be equivalent. The following example illustrates some of the subtleties of processes in continuous time.

Suppose that $\Omega = T = [0, \infty)$, $\mathcal{F} = \mathcal{T}$ is the σ -algebra of Borel measurable subsets of $[0, \infty)$, and \mathbb{P} is any continuous probability measure on (Ω, \mathcal{F}) . Let $S = \{0, 1\}$ and $\mathcal{S} = \mathcal{P}(S) = \{\emptyset, \{0\}, \{1\}, \{0, 1\}\}$. For $t \in T$ and $\omega \in \Omega$, define $X_t(\omega) = \mathbf{1}_t(\omega)$ and $Y_t(\omega) = 0$. Then

1. $\mathbf{X} = \{X_t : t \in T\}$ is a version of $\mathbf{Y} = \{Y_t : t \in T\}$
2. \mathbf{X} is not adapted to the natural filtration of \mathbf{Y} .

Proof

1. This was shown in the previous section, but here it is again: For $t \in T$, $\mathbb{P}(X_t \neq Y_t) = \mathbb{P}(\{t\}) = 0$.
2. Trivially, $\sigma(Y_t) = \{\emptyset, \Omega\}$ for every $t \in T$, so $\sigma\{Y_s : 0 \leq s \leq t\} = \{\emptyset, \Omega\}$. But $\sigma(X_t) = \{\emptyset, \{t\}, \Omega \setminus \{t\}, \Omega\}$

Completion

Suppose now that P is a probability measure on (Ω, \mathcal{F}) . Recall that \mathcal{F} is complete with respect to P if $A \in \mathcal{F}$, $B \subseteq A$, and $P(A) = 0$ imply $B \in \mathcal{F}$ (and hence $P(B) = 0$). That is, if A is an event with probability 0 and $B \subseteq A$, then B is also an event (and also has probability 0). For a filtration, the following definition is appropriate.

The filtration $\{\mathcal{F}_t : t \in T\}$ is *complete* with respect to a probability measure P on (Ω, \mathcal{F}) if

1. \mathcal{F} is complete with respect to P
2. If $A \in \mathcal{F}$ and $P(A) = 0$ then $A \in \mathcal{F}_0$.

Suppose P is a probability measure on (Ω, \mathcal{F}) and that the filtration $\{\mathcal{F}_t : t \in T\}$ is complete with respect to P . If $A \in \mathcal{F}$ is a null event ($P(A) = 0$) or an almost certain event ($P(A) = 1$) then $A \in \mathcal{F}_t$ for every $t \in T$.

Proof

This follows since almost certain events are complements of null events and since the σ -algebras are increasing in $t \in T$.

Recall that if P is a probability measure on (Ω, \mathcal{F}) , but \mathcal{F} is not complete with respect to P , then \mathcal{F} can always be *completed*. Here's a review of how this is done: Let

$$\mathcal{N} = \{A \subseteq \Omega : \text{there exists } N \in \mathcal{F} \text{ with } P(N) = 0 \text{ and } A \subseteq N\} \quad (2.11.2)$$

So \mathcal{N} is the collection of null sets. Then we let $\mathcal{F}^P = \sigma(\mathcal{F} \cup \mathcal{N})$ and extend P to \mathcal{F}^P in the natural way: if $A \in \mathcal{F}^P$ and A differs from $B \in \mathcal{F}$ by a null set, then $P(A) = P(B)$. Filtrations can also be completed.

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) and that P is a probability measure on (Ω, \mathcal{F}) . As above, let \mathcal{N} denote the collection of null subsets of Ω , and for $t \in T$, let $\mathcal{F}_t^P = \sigma(\mathcal{F}_t \cup \mathcal{N})$. Then $\mathfrak{F}^P = \{\mathcal{F}_t^P : t \in T\}$ is a filtration on (Ω, \mathcal{F}^P) that is finer than \mathfrak{F} and is complete relative to P .

Proof

If $s, t \in T$ with $s \leq t$ then $\mathcal{F}_s \subseteq \mathcal{F}_t \subseteq \mathcal{F}$ and hence

$$\sigma(\mathcal{F}_s \cup \mathcal{N}) \subseteq \sigma(\mathcal{F}_t \cup \mathcal{N}) \subseteq \sigma(\mathcal{F} \cup \mathcal{N}) \quad (2.11.3)$$

and so $\mathcal{F}_s^P \subseteq \mathcal{F}_t^P \subseteq \mathcal{F}^P$. The probability measure P can be extended to \mathcal{F}^P as described above, and hence is defined on \mathcal{F}_t^P for each $t \in T$. By construction, if $A \in \mathcal{F}^P$ and $P(A) = 0$ then $A \in \mathcal{N}$ so \mathfrak{F}^P is complete with respect to P .

Naturally, \mathfrak{F}^P is the *completion* of \mathfrak{F} with respect to P . Sometimes we need to consider *all* probability measures on (Ω, \mathcal{F}) .

Let \mathcal{P} denote the collection of probability measures on (Ω, \mathcal{F}) , and suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) . Let $\mathcal{F}^* = \bigcap \{\mathcal{F}^P : P \in \mathcal{P}\}$, and let $\mathfrak{F}^* = \bigwedge \{\mathfrak{F}^P : P \in \mathcal{P}\}$. Then \mathfrak{F}^* is a filtration on (Ω, \mathcal{F}^*) , known as the *universal completion* of \mathfrak{F} .

Proof

Note that \mathfrak{F}^P is a filtration on (Ω, \mathcal{F}^P) for each $P \in \mathcal{P}$, so \mathfrak{F}^* is a filtration on (Ω, \mathcal{F}^*) .

The last definition must seem awfully obscure, but it does have a place. In the theory of Markov processes, we usually allow arbitrary initial distributions, which in turn produces a large collection of distributions on the sample space.

Right Continuity

In continuous time, we sometimes need to refine a given filtration somewhat.

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in [0, \infty)\}$ is a filtration on (Ω, \mathcal{F}) . For $t \in [0, \infty)$, define $\mathcal{F}_{t+} = \bigcap \{\mathcal{F}_s : s \in (t, \infty)\}$. Then $\mathfrak{F}_+ = \{\mathcal{F}_{t+} : t \in T\}$ is also a filtration on (Ω, \mathcal{F}) and is finer than \mathfrak{F} .

Proof

For $t \in [0, \infty)$ note that \mathcal{F}_{t+} is a σ -algebra since it is the intersection of σ -algebras, and clearly $\mathcal{F}_{t+} \subseteq \mathcal{F}$. Next, if $s, t \in [0, \infty)$ with $s \leq t$, then $\{\mathcal{F}_r : r \in (t, \infty)\} \subseteq \{\mathcal{F}_r : r \in (s, \infty)\}$, so it follows that

$$\mathcal{F}_{s+} = \bigcap \{\mathcal{F}_r : r \in (s, \infty)\} \subseteq \bigcap \{\mathcal{F}_r : r \in (t, \infty)\} = \mathcal{F}_{t+} \quad (2.11.4)$$

Finally, for $t \in [0, \infty)$, $\mathcal{F}_t \subseteq \mathcal{F}_s$ for every $s \in (t, \infty)$ so $\mathcal{F}_t \subseteq \bigcap \{\mathcal{F}_s : s \in (t, \infty)\} = \mathcal{F}_{t+}$.

Since the σ -algebras in a filtration are increasing, it follows that for $t \in [0, \infty)$, $\mathcal{F}_{t+} = \bigcap \{\mathcal{F}_s : s \in (t, t+\epsilon)\}$ for every $\epsilon \in (0, \infty)$. So if the filtration \mathfrak{F} encodes the information available as time goes by, then the filtration \mathfrak{F}_+ allows an “infinitesimal peak into the future” at each $t \in [0, \infty)$. In light of the previous result, the next definition is natural.

A filtration $\mathfrak{F} = \{\mathcal{F}_t : t \in [0, \infty)\}$ is *right continuous* if $\mathfrak{F}_+ = \mathfrak{F}$, so that $\mathcal{F}_{t+} = \mathcal{F}_t$ for every $t \in [0, \infty)$.

Right continuous filtrations have some nice properties, as we will see later. If the original filtration is not right continuous, the slightly refined filtration is:

Suppose again that $\mathcal{F} = \{\mathcal{F}_t : t \in [0, \infty)\}$ is a filtration. Then \mathcal{F}_+ is a right continuous filtration.

Proof

For $t \in T$

$$\mathcal{F}_{t++} = \bigcap \{\mathcal{F}_{s+} : s \in (t, \infty)\} = \bigcap \left\{ \bigcap \{\mathcal{F}_r : r \in (s, \infty)\} : s \in (t, \infty) \right\} = \bigcap \{\mathcal{F}_u : u \in (t, \infty)\} = \mathcal{F}_{t+} \quad (2.11.5)$$

For a stochastic process $\mathbf{X} = \{X_t : t \in [0, \infty)\}$ in continuous time, often the filtration \mathcal{F} that is most useful is the right-continuous refinement of the natural filtration. That is, $\mathcal{F} = \mathcal{F}_+$, so that $\mathcal{F}_t = \sigma\{X_s : s \in [0, t]\}_+$ for $t \in [0, \infty)$.

Stopping Times

Basic Properties

Suppose again that we have a fixed sample space (Ω, \mathcal{F}) . Random variables taking values in the time set T are important, but often as we will see, it's necessary to allow such variables to take the value ∞ as well as finite times. So let $T_\infty = T \cup \{\infty\}$. We extend order to T_∞ by the obvious rule that $t < \infty$ for every $t \in T$. We also extend the topology on T to T_∞ by the rule that for each $s \in T$, the set $\{t \in T_\infty : t > s\}$ is an open neighborhood of ∞ . That is, T_∞ is the *one-point compactification* of T . The reason for this is to preserve the meaning of *time converging to infinity*. That is, if (t_1, t_2, \dots) is a sequence in T_∞ then $t_n \rightarrow \infty$ as $n \rightarrow \infty$ if and only if, for every $t \in T$ there exists $m \in \mathbb{N}_+$ such that $t_n > t$ for $n > m$. We then give T_∞ the Borel σ -algebra \mathcal{T}_∞ as before. In discrete time, this is once again the discrete σ -algebra, so that all subsets are measurable. In both cases, we now have an enhanced time space is $(T_\infty, \mathcal{T}_\infty)$. A random variable τ taking values in T_∞ is called a *random time*.

Suppose that $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) . A random time τ is a *stopping time* relative to \mathcal{F} if $\{\tau \leq t\} \in \mathcal{F}_t$ for each $t \in T$.

In a sense, a stopping time is a random time that does not require that we see into the future. That is, we can tell whether or not $\tau \leq t$ from our information at time t . The term *stopping time* comes from gambling. Consider a gambler betting on games of chance. The gambler's decision to stop gambling at some point in time and accept his fortune must define a stopping time. That is, the gambler can base his decision to stop gambling on all of the information that he has at that point in time, but not on what will happen in the future. The terms *Markov time* and *optional time* are sometimes used instead of stopping time. If τ is a stopping time relative to a filtration, then it is also a stopping time relative to any finer filtration:

Suppose that $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ and $\mathcal{G} = \{\mathcal{G}_t : t \in T\}$ are filtrations on (Ω, \mathcal{F}) , and that \mathcal{G} is finer than \mathcal{F} . If a random time τ is a stopping time relative to \mathcal{F} then τ is a stopping time relative to \mathcal{G} .

Proof

This is very simple. If $t \in T$ then $\{\tau \leq t\} \in \mathcal{F}_t$ and hence $\{\tau \leq t\} \in \mathcal{G}_t$ since $\mathcal{F}_t \subseteq \mathcal{G}_t$.

So, the finer the filtration, the larger the collection of stopping times. In fact, *every* random time is a stopping time relative to the finest filtration \mathcal{F} where $\mathcal{F}_t = \mathcal{F}$ for every $t \in T$. But this filtration corresponds to having complete information from the beginning of time, which of course is usually not sensible. At the other extreme, for the coarsest filtration \mathcal{F} where $\mathcal{F}_t = \{\Omega, \emptyset\}$ for every $t \in T$, the only stopping times are constants. That is, random times of the form $\tau(\omega) = t$ for every $\omega \in \Omega$, for some $t \in T_\infty$.

Suppose again that $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) . A random time τ is a stopping time relative to \mathcal{F} if and only if $\{\tau > t\} \in \mathcal{F}_t$ for each $t \in T$.

Proof

This result is trivial since $\{\tau > t\} = \{\tau \leq t\}^c$ for $t \in T$.

Suppose again that $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) , and that τ is a stopping time relative to \mathcal{F} . Then

1. $\{\tau < t\} \in \mathcal{F}_t$ for every $t \in T$.
2. $\{\tau \geq t\} \in \mathcal{F}_t$ for every $t \in T$.
3. $\{\tau = t\} \in \mathcal{F}_t$ for every $t \in T$.

Proof

1. Suppose first that $T = \mathbb{N}$. Then $\{\tau < t\} = \{\tau \leq t-1\} \in \mathcal{F}_{t-1} \subseteq \mathcal{F}_t$ for $t \in \mathbb{N}$. Next suppose that $T = [0, \infty)$. Fix $t \in (0, \infty)$ and let (s_1, s_2, \dots) be a strictly increasing sequence in $[0, \infty)$ with $s_n \uparrow t$ as $n \rightarrow \infty$. Then $\{\tau < t\} = \bigcup_{n=1}^{\infty} \{\tau \leq s_n\}$. But $\{\tau \leq s_n\} \in \mathcal{F}_{s_n} \subseteq \mathcal{F}_t$ for each n , so $\{\tau < t\} \in \mathcal{F}_t$.
2. This follows from (a) since $\{\tau \geq t\} = \{\tau < t\}^c$ for $t \in T$.
3. For $t \in T$ note that $\{\tau = t\} = \{\tau \leq t\} \setminus \{\tau < t\}$. Both events in the set difference are in \mathcal{F}_t .

Note that when $T = \mathbb{N}$, we actually showed that $\{\tau < t\} \in \mathcal{F}_{t-1}$ and $\{\tau \geq t\} \in \mathcal{F}_{t-1}$. The converse to part (a) (or equivalently (b)) is not true, but in continuous time there is a connection to the right-continuous refinement of the filtration.

Suppose that $T = [0, \infty)$ and that $\mathfrak{F} = \{\mathcal{F}_t : t \in [0, \infty)\}$ is a filtration on (Ω, \mathcal{F}) . A random time τ is a stopping time relative to \mathfrak{F}_+ if and only if $\{\tau < t\} \in \mathcal{F}_t$ for every $t \in [0, \infty)$.

Proof

So restated, we need to show that $\{\tau \leq t\} \in \mathcal{F}_{t+}$ for every $t \in [0, \infty)$ if and only if $\{\tau < t\} \in \mathcal{F}_t$ for every $t \in [0, \infty)$. (Note by the way, that this is not the same as the statement that for every $t \in T$, $\{\tau < t\} \in \mathcal{F}_{t+}$ if and only if $\{\tau \leq t\} \in \mathcal{F}_t$, which is not true.) Suppose first that τ is a stopping time relative to \mathfrak{F} . Fix $t \in [0, \infty)$ and let (t_1, t_2, \dots) be a strictly decreasing sequence in $[0, \infty)$ with $t_n \downarrow t$ as $n \rightarrow \infty$. Then for each $k \in \mathbb{N}_+$, $\{\tau \leq t\} = \bigcap_{n=k}^{\infty} \{\tau < t_n\}$. If $s > t$ then there exists $k \in \mathbb{N}_+$ such that $t_n < s$ for each $n \geq k$. Hence $\{\tau < t_n\} \in \mathcal{F}_{t_n} \subseteq \mathcal{F}_s$ for $n \geq k$, and so it follows that $\{\tau \leq t\} \in \mathcal{F}_s$. Since this is true for every $s > t$ it follows $\{\tau \leq t\} \in \mathcal{F}_{t+}$. Conversely, suppose that $\{\tau \leq t\} \in \mathcal{F}_{t+}$ for every $t \in [0, \infty)$. Fix $t \in (0, \infty)$ and let (t_1, t_2, \dots) be a strictly increasing sequence in $(0, \infty)$ with $t_n \uparrow t$ as $n \rightarrow \infty$. Then $\bigcup_{i=1}^{\infty} \{\tau \leq t_n\} = \{\tau < t\}$. But for every $n \in \mathbb{N}_+$

$$\{\tau \leq t_n\} \in \mathcal{F}_{t_n+} = \bigcap \{\mathcal{F}_s : s \in (t_n, t)\} \subseteq \mathcal{F}_t \quad (2.11.6)$$

Hence $\{\tau < t\} \in \mathcal{F}_t$.

If $\mathfrak{F} = \{\mathcal{F}_t : t \in [0, \infty)\}$ is a filtration and τ is a random time that satisfies $\{\tau < t\} \in \mathcal{F}_t$ for every $t \in T$, then some authors call τ a *weak stopping time* or say that τ is *weakly optional* for the filtration \mathfrak{F} . But to me, the increase in jargon is not worthwhile, and it's better to simply say that τ is a stopping time for the filtration \mathfrak{F}_+ . The following corollary now follows.

Suppose that $T = [0, \infty)$ and that $\mathfrak{F} = \{\mathcal{F}_t : t \in [0, \infty)\}$ is a right-continuous filtration. A random time τ is a stopping time relative to \mathfrak{F} if and only if $\{\tau < t\} \in \mathcal{F}_t$ for every $t \in [0, \infty)$.

The converse to part (c) of the result [above](#) holds in discrete time.

Suppose that $T = \mathbb{N}$ and that $\mathfrak{F} = \{\mathcal{F}_n : n \in \mathbb{N}\}$ is a filtration on (Ω, \mathcal{F}) . A random time τ is a stopping time for \mathfrak{F} if and only if $\{\tau = n\} \in \mathcal{F}_n$ for every $n \in \mathbb{N}$.

Proof

If τ is a stopping time then as shown [above](#), $\{\tau = n\} \in \mathcal{F}_n$ for every $n \in \mathbb{N}$. Conversely, suppose that this condition holds. For $n \in \mathbb{N}$, $\{\tau \leq n\} = \bigcup_{k=0}^n \{\tau = k\}$. But $\{\tau = k\} \in \mathcal{F}_k \subseteq \mathcal{F}_n$ for $k \in \{0, 1, \dots, n\}$ so $\{\tau \leq n\} \in \mathcal{F}_n$.

Basic Constructions

As noted above, a constant element of T_∞ is a stopping time, but not a very interesting one.

Suppose $s \in T_\infty$ and that $\tau(\omega) = s$ for all $\omega \in \Omega$. The τ is a stopping time relative to any filtration on (Ω, \mathcal{F}) .

Proof

For $t \in T$ note that $\{\tau \leq t\} = \Omega$ if $s \leq t$ and $\{\tau \leq t\} = \emptyset$ if $s > t$.

If the filtration $\{\mathcal{F}_t : t \in T\}$ is complete, then a random time that is almost certainly a constant is also a stopping time. The following theorems give some basic ways of constructing new stopping times from ones we already have.

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) and that τ_1 and τ_2 are stopping times relative to \mathfrak{F} . Then each of the following is also a stopping time relative to \mathfrak{F} :

1. $\tau_1 \vee \tau_2 = \max\{\tau_1, \tau_2\}$
2. $\tau_1 \wedge \tau_2 = \min\{\tau_1, \tau_2\}$
3. $\tau_1 + \tau_2$

Proof

1. Note that $\{\tau_1 \vee \tau_2 \leq t\} = \{\tau_1 \leq t\} \cap \{\tau_2 \leq t\} \in \mathcal{F}_t$ for $t \in T$, so the result follows from the definition.
2. Note that $\{\tau_1 \wedge \tau_2 > t\} = \{\tau_1 > t\} \cap \{\tau_2 > t\} \in \mathcal{F}_t$ for $t \in T$, so the result follows from the [result above](#).
3. This is simple when $T = \mathbb{N}$. In this case, $\{\tau_1 + \tau_2 \leq t\} = \bigcup_{n=0}^t \{\tau_1 = n\} \cap \{\tau_2 \leq t - n\}$. But for $n \leq t$, $\{\tau_1 = n\} \in \mathcal{F}_n \subseteq \mathcal{F}_t$ and $\{\tau_2 \leq t - n\} \in \mathcal{F}_{t-n} \subseteq \mathcal{F}_t$. Hence $\{\tau_1 + \tau_2 \leq t\} \in \mathcal{F}_t$. Suppose instead that $T = [0, \infty)$ and $t \in T$. Then $\tau_1 + \tau_2 > t$ if and only if either $\tau_1 \leq t$ and $\tau_2 > t - \tau_1$ or $\tau_1 > t$. Of course $\{\tau_1 > t\} \in \mathcal{F}_t$ so we just need to show that the first event is also in \mathcal{F}_t . Note that $\tau_1 \leq t$ and $\tau_2 > t - \tau_1$ if and only if there exists a rational $q \in [0, t]$ such that $q \leq \tau_1 \leq t$ and $\tau_2 \geq t - q$. Each of these events is in \mathcal{F}_t and hence so is the union of the events over the countable collection of rational $q \in [0, t]$.

It follows that if $(\tau_1, \tau_2, \dots, \tau_n)$ is a finite sequence of stopping times relative to \mathfrak{F} , then each of the following is also a stopping time relative to \mathfrak{F} :

- $\tau_1 \vee \tau_2 \vee \dots \vee \tau_n$
- $\tau_1 \wedge \tau_2 \wedge \dots \wedge \tau_n$
- $\tau_1 + \tau_2 + \dots + \tau_n$

We have to be careful when we try to extend these results to infinite sequences.

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) , and that $(\tau_n : n \in \mathbb{N}_+)$ is a sequence of stopping times relative to \mathfrak{F} . Then $\sup\{\tau_n : n \in \mathbb{N}_+\}$ is also a stopping time relative to \mathfrak{F} .

Proof

Let $\tau = \sup\{\tau_n : n \in \mathbb{N}_+\}$. Note that τ exists in T_∞ and is a random time. For $t \in T$, $\{\tau \leq t\} = \bigcap_{n=1}^\infty \{\tau_n \leq t\}$. But each event in the intersection is in \mathcal{F}_t and hence so is the intersection.

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) , and that $(\tau_n : n \in \mathbb{N}_+)$ is an increasing sequence of stopping times relative to \mathfrak{F} . Then $\lim_{n \rightarrow \infty} \tau_n$ is a stopping time relative to \mathfrak{F} .

Proof

This is a corollary of the previous theorem. Since the sequence is increasing, $\lim_{n \rightarrow \infty} \tau_n = \sup\{\tau_n : n \in \mathbb{N}_+\}$.

Suppose that $T = [0, \infty)$ and that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) . If $(\tau_n : n \in \mathbb{N}_+)$ is a sequence of stopping times relative to \mathfrak{F} , then each of the following is a stopping time relative to \mathfrak{F}_+ :

1. $\inf\{\tau_n : n \in \mathbb{N}_+\}$
2. $\liminf_{n \rightarrow \infty} \tau_n$
3. $\limsup_{n \rightarrow \infty} \tau_n$

Proof

1. Let $\tau = \inf\{\tau_n : n \in \mathbb{N}_+\}$. Then $\{\tau \geq t\} = \bigcap_{n=1}^\infty \{\tau_n \geq t\} \in \mathcal{F}_t$ for $t \in T$. Hence τ is a stopping time relative to \mathfrak{F}_+ by the result above.
2. Recall that $\liminf_{n \rightarrow \infty} \tau_n = \sup\{\inf\{\tau_k : k \geq n\} : n \in \mathbb{N}_+\}$ and so this is a stopping time relative to \mathfrak{F}_+ by part (a) and the [result above](#) on supremums.
3. Similarly note that $\limsup_{n \rightarrow \infty} \tau_n = \inf\{\sup\{\tau_k : k \geq n\} : n \in \mathbb{N}_+\}$ and so this is a stopping time relative to \mathfrak{F}_+ by part (a) and the [result above](#) on supremums.

As a simple corollary, we have the following results:

Suppose that $T = [0, \infty)$ and that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a right-continuous filtration on (Ω, \mathcal{F}) . If $(\tau_n : n \in \mathbb{N}_+)$ is a sequence of stopping times relative to \mathfrak{F} , then each of the following is also a stopping time relative to \mathfrak{F} :

1. $\inf\{\tau_n : n \in \mathbb{N}_+\}$
2. $\liminf_{n \rightarrow \infty} \tau_n$

3. $\limsup_{n \rightarrow \infty} \tau_n$

The σ -Algebra of a Stopping Time

Consider again the general setting of a filtration $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ on the sample space (Ω, \mathcal{F}) , and suppose that τ is a stopping time relative to \mathfrak{F} . We want to define the σ -algebra \mathcal{F}_τ of events up to the random time τ , analogous to \mathcal{F}_t the σ -algebra of events up to a fixed time $t \in T$. Here is the appropriate definition:

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) and that τ is a stopping time relative to \mathfrak{F} . Define $\mathcal{F}_\tau = \{A \in \mathcal{F} : A \cap \{\tau \leq t\} \in \mathcal{F}_t \text{ for all } t \in T\}$. Then \mathcal{F}_τ is a σ -algebra.

Proof

First $\Omega \in \mathcal{F}_\tau$ since $\Omega \cap \{\tau \leq t\} = \{\tau \leq t\} \in \mathcal{F}_t$ for $t \in T$. If $A \in \mathcal{F}_\tau$ then $A^c \cap \{\tau \leq t\} = \{\tau \leq t\} \setminus (A \cap \{\tau \leq t\}) \in \mathcal{F}_t$ for $t \in T$. Finally, suppose that $A_i \in \mathcal{F}_\tau$ for i in a countable index set I . Then $(\bigcup_{i \in I} A_i) \cap \{\tau \leq t\} = \bigcup_{i \in I} (A_i \cap \{\tau \leq t\}) \in \mathcal{F}_t$ for $t \in T$.

Thus, an event A is in \mathcal{F}_τ if we can determine if A and $\tau \leq t$ both occurred given our information at time t . If τ is constant, then \mathcal{F}_τ reduces to the corresponding member of the original filtration, which clearly should be the case, and is additional motivation for the definition.

Suppose again that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) . Fix $s \in T$ and define $\tau(\omega) = s$ for all $\omega \in \Omega$. Then $\mathcal{F}_\tau = \mathcal{F}_s$.

Proof

Suppose that $A \in \mathcal{F}_s$. Then $A \in \mathcal{F}$ and for $t \in T$, $A \cap \{\tau \leq t\} = A$ if $s \leq t$ and $A \cap \{\tau \leq t\} = \emptyset$ if $s > t$. In either case, $A \cap \{\tau \leq t\} \in \mathcal{F}_t$ and hence $A \in \mathcal{F}_\tau$. Conversely, suppose that $A \in \mathcal{F}_\tau$. Then $A = A \cap \{\tau \leq s\} \in \mathcal{F}_s$.

Clearly, if we have the information available in \mathcal{F}_τ , then we should know the value of τ itself. This is also true:

Suppose again that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) and that τ is a stopping time relative to \mathfrak{F} . Then τ is measurable with respect to \mathcal{F}_τ .

Proof

It suffices to show that $\{\tau \leq s\} \in \mathcal{F}_\tau$ for each $s \in T$. For $s, t \in T$,

$$\{\tau \leq t\} \cap \{\tau \leq s\} = \{\tau \leq s \wedge t\} \in \mathcal{F}_{s \wedge t} \subseteq \mathcal{F}_t \quad (2.11.7)$$

Hence $\{\tau \leq s\} \in \mathcal{F}_\tau$.

Here are other results that relate the σ -algebra of a stopping time to the original filtration.

Suppose again that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) and that τ is a stopping time relative to \mathfrak{F} . If $A \in \mathcal{F}_\tau$ then for $t \in T$,

1. $A \cap \{\tau < t\} \in \mathcal{F}_t$
2. $A \cap \{\tau = t\} \in \mathcal{F}_t$

Proof

1. By definition, $A \cap \{\tau \leq t\} \in \mathcal{F}_t$. But $\{\tau < t\} \subseteq \{\tau \leq t\}$ and $\{\tau < t\} \in \mathcal{F}_t$. Hence

$$A \cap \{\tau < t\} = A \cap \{\tau \leq t\} \cap \{\tau < t\} \in \mathcal{F}_t.$$

2. similarly $\{\tau = t\} \subseteq \{\tau \leq t\}$ and $\{\tau = t\} \in \mathcal{F}_t$. Hence $A \cap \{\tau = t\} = A \cap \{\tau \leq t\} \cap \{\tau = t\} \in \mathcal{F}_t$

The σ -algebra of a stopping time relative to a filtration is related to the σ -algebra of the stopping time relative to a finer filtration in the natural way.

Suppose that $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ and $\mathfrak{G} = \{\mathcal{G}_t : t \in T\}$ are filtrations on (Ω, \mathcal{F}) and that \mathfrak{G} is finer than \mathfrak{F} . If τ is a stopping time relative to \mathfrak{F} then $\mathcal{F}_\tau \subseteq \mathcal{G}_\tau$.

Proof

From the result above, τ is also a stopping time relative to \mathfrak{G} , so the statement makes sense. If $A \in \mathcal{F}_\tau$ then for $t \in T$, $A \cap \{\tau \leq t\} \in \mathcal{F}_t \subseteq \mathcal{G}_t$, so $A \in \mathcal{G}_\tau$.

When two stopping times are ordered, their σ -algebras are also ordered.

Suppose that $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) and that ρ and τ are stopping times for \mathcal{F} with $\rho \leq \tau$. Then $\mathcal{F}_\rho \subseteq \mathcal{F}_\tau$.

Proof

Suppose that $A \in \mathcal{F}_\rho$ and $t \in T$. Note that $\{\tau \leq t\} \subseteq \{\rho \leq t\}$. By definition, $A \cap \{\rho \leq t\} \in \mathcal{F}_t$ and $\{\tau \leq t\} \in \mathcal{F}_t$. Hence $A \cap \{\tau \leq t\} = A \cap \{\rho \leq t\} \cap \{\tau \leq t\} \in \mathcal{F}_t$, so $A \in \mathcal{F}_\tau$.

Suppose again that $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) , and that ρ and τ are stopping times for \mathcal{F} . Then each of the following events is in \mathcal{F}_τ and in \mathcal{F}_ρ .

1. $\{\rho < \tau\}$
2. $\{\rho = \tau\}$
3. $\{\rho > \tau\}$
4. $\{\rho \leq \tau\}$
5. $\{\rho \geq \tau\}$

Proof

The proofs are easy when $T = \mathbb{N}$.

1. Let $t \in T$. Then

$$\{\rho < \tau\} \cap \{\tau \leq t\} = \bigcup_{n=0}^t \bigcup_{k=0}^{n-1} \{\tau = n, \rho = k\} \quad (2.11.8)$$

But each event in the union is in \mathcal{F}_t .

2. Similarly, let $t \in T$. Then

$$\{\rho = \tau\} \cap \{\tau \leq t\} = \bigcup_{n=0}^t \{\rho = n, \tau = n\} \quad (2.11.9)$$

and again each event in the union is in \mathcal{F}_t .

3. This follows from symmetry, reversing the roles of ρ and τ in part (a).
4. Note that $\{\rho \leq \tau\} = \{\rho < \tau\} \cup \{\rho = \tau\} \in \mathcal{F}_\tau$.
5. Similarly, note that $\{\rho \geq \tau\} = \{\rho > \tau\} \cup \{\rho = \tau\} \in \mathcal{F}_\tau$.

We can “stop” a filtration at a stopping time. In the next subsection, we will stop a stochastic process in the same way.

Suppose again that $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$ is a filtration on (Ω, \mathcal{F}) , and that τ is a stopping times for \mathcal{F} . For $t \in T$ define $\mathcal{F}_t^\tau = \mathcal{F}_{t \wedge \tau}$. Then $\mathcal{F}^\tau = \{\mathcal{F}_t^\tau : t \in T\}$ is a filtration and is coarser than \mathcal{F} .

Proof

The random time $t \wedge \tau$ is a stopping time for each $t \in T$ by the result above, so \mathcal{F}_t^τ is a sub σ -algebra of \mathcal{F} . If $t \in T$, then by definition, $A \in \mathcal{F}_t^\tau$ if and only if $A \cap \{t \wedge \tau \leq r\} \in \mathcal{F}_r$ for every $r \in T$. But for $r \in T$, $\{t \wedge \tau \leq r\} = \Omega$ if $r \geq t$ and $\{t \wedge \tau \leq r\} = \{\tau \leq r\}$ if $r < t$. Hence $A \in \mathcal{F}_t^\tau$ if and only if $A \cap \{\tau \leq r\} \in \mathcal{F}_r$ for $r < t$ and $A \in \mathcal{F}_t$. So in particular, \mathcal{F}^τ is coarser than \mathcal{F} . Further, suppose $s, t \in T$ with $s \leq t$, and that $A \in \mathcal{F}_s^\tau$. Let $r \in T$. If $r < s$ then $A \cap \{\tau \leq r\} \in \mathcal{F}_r$. If $s \leq r < t$ then $A \in \mathcal{F}_s \subseteq \mathcal{F}_r$ and $\{\tau \leq r\} \in \mathcal{F}_r$ so again $A \cap \{\tau \leq r\} \in \mathcal{F}_r$. Finally if $r \geq t$ then $A \in \mathcal{F}_s \subseteq \mathcal{F}_t$. Hence $A \in \mathcal{F}_t^\tau$.

Stochastic Processes

As usual, the most common setting is when we have a stochastic process $\mathbf{X} = \{X_t : t \in T\}$ defined on our sample space (Ω, \mathcal{F}) and with state space (S, \mathcal{S}) . If τ is a random time, we are often interested in the state X_τ at the random time. But there are two issues. First, τ may take the value infinity, in which case X_τ is not defined. The usual solution is to introduce a new “death state” δ , and define $X_\infty = \delta$. The σ -algebra \mathcal{S} on S is extended to $S_\delta = S \cup \{\delta\}$ in the natural way, namely $\mathcal{S}_\delta = \sigma(S \cup \{\delta\})$.

Our other problem is that we naturally expect X_τ to be a random variable (that is, measurable), just as X_t is a random variable for a deterministic $t \in T$. Moreover, if \mathbf{X} is adapted to a filtration $\mathcal{F} = \{\mathcal{F}_t : t \in T\}$, then we would naturally also expect X_τ to be

measurable with respect to \mathcal{F}_τ , just as X_t is measurable with respect to \mathcal{F}_t for deterministic $t \in T$. But this is not obvious, and in fact is not true without additional assumptions. Note that X_τ is a random state at a random time, and so depends on an outcome $\omega \in \Omega$ in two ways: $X_{\tau(\omega)}(\omega)$.

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process on the sample space (Ω, \mathcal{F}) with state space (S, \mathcal{S}) , and that \mathbf{X} is measurable. If τ is a finite random time, then X_τ is measurable. That is, X_τ is a random variable with values in S .

Proof

Note that $X_\tau : \Omega \rightarrow S$ is the composition of the function $\omega \mapsto (\omega, \tau(\omega))$ from Ω to $\Omega \times T$ with the function $(\omega, t) \mapsto X_t(\omega)$ from $\Omega \times T$ to S . The first function is measurable because the two coordinate functions are measurable. The second function is measurable by assumption.

This result is one of the main reasons for the definition of a measurable process in the first place. Sometimes we literally want to *stop* the random process at a random time τ . As you might guess, this is the origin of the term *stopping time*.

Suppose again that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process on the sample space (Ω, \mathcal{F}) with state space (S, \mathcal{S}) , and that \mathbf{X} is measurable. If τ is a random time, then the process $\mathbf{X}^\tau = \{X_t^\tau : t \in T\}$ defined by $X_t^\tau = X_{t \wedge \tau}$ for $t \in T$ is the process \mathbf{X} *stopped at τ* .

Proof

For each $t \in T$, note that $t \wedge \tau$ is a finite random time, and hence $X_{t \wedge \tau}$ is measurable by the previous result. Thus \mathbf{X}^τ is a well-defined stochastic process on (Ω, \mathcal{F}) with state space (S, \mathcal{S}) .

When the original process is progressively measurable, so is the stopped process.

Suppose again that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process on the sample space (Ω, \mathcal{F}) with state space (S, \mathcal{S}) , and that \mathbf{X} is progressively measurable with respect to a filtration $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$. If τ is a stopping time relative to \mathfrak{F} , then the stopped process $\mathbf{X}^\tau = \{X_t^\tau : t \in T\}$ is progressively measurable with respect to the stopped filtration \mathfrak{F}^τ .

Since \mathfrak{F} is finer than \mathfrak{F}^τ , it follows that \mathbf{X}^τ is also progressively measurable with respect to \mathfrak{F} .

Suppose again that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process on the sample space (Ω, \mathcal{F}) with state space (S, \mathcal{S}) , and that \mathbf{X} is progressively measurable with respect to a filtration $\mathfrak{F} = \{\mathcal{F}_t : t \in T\}$ on (Ω, \mathcal{F}) . If τ is a finite stopping time relative to \mathfrak{F} then X_τ is measurable with respect to \mathcal{F}_τ .

For many random processes, the first time that the process enters or hits a set of states is particularly important. In the discussion that follows, let $T_+ = \{t \in T : t > 0\}$, the set of positive times.

Suppose that $\mathbf{X} = \{X_t : t \in T\}$ is a stochastic process on (Ω, \mathcal{F}) with state space (S, \mathcal{S}) . For $A \in \mathcal{S}$, define

1. $\rho_A = \inf\{t \in T : X_t \in A\}$, the first *entry time* to A .
2. $\tau_A = \inf\{t \in T_+ : X_t \in A\}$, the first *hitting time* to A .

As usual, $\inf(\emptyset) = \infty$ so $\rho_A = \infty$ if $X_t \notin A$ for all $t \in T$, so that the process never enters A , and $\tau_A = \infty$ if $X_t \notin A$ for all $t \in T_+$, so that the process never hits A . In discrete time, it's easy to see that these are stopping times.

Suppose that $\{X_n : n \in \mathbb{N}\}$ is a stochastic process on (Ω, \mathcal{F}) with state space (S, \mathcal{S}) . If $A \in \mathcal{S}$ then τ_A and ρ_A are stopping times relative to the natural filtration \mathfrak{F}^0 .

Proof

Let $n \in \mathbb{N}$. Note that $\{\rho_A > n\} = \{X_0 \notin A, X_1 \notin A, \dots, X_n \notin A\} \in \sigma\{X_0, X_1, \dots, X_n\}$. Similarly, $\{\tau_A > n\} = \{X_1 \notin A, X_2 \notin A, \dots, X_n \notin A\} \subseteq \sigma\{X_0, X_1, \dots, X_n\}$.

So of course in discrete time, τ_A and ρ_A are stopping times relative to any filtration \mathfrak{F} to which \mathbf{X} is adapted. You might think that τ_A and ρ_A should always be stopping times, since $\tau_A \leq t$ if and only if $X_s \in A$ for some $s \in T_+$ with $s \leq t$, and $\rho_A \leq t$ if and only if $X_s \in A$ for some $s \in T$ with $s \leq t$. It would seem that these events are known if one is allowed to observe the process up to time t .

The problem is that when $T = [0, \infty)$, these are uncountable unions, so we need to make additional assumptions on the stochastic process \mathbf{X} or the filtration \mathfrak{F} , or both.

Suppose that S has an LCCB topology, and that \mathcal{S} is the σ -algebra of Borel sets. Suppose also that $\mathbf{X} = \{X_t : t \in [0, \infty)\}$ is right continuous and has left limits. Then τ_A and ρ_A are stopping times relative to \mathfrak{F}_+^0 for every open $A \in \mathcal{S}$.

Here is another result that requires less of the stochastic process \mathbf{X} , but more of the filtration \mathfrak{F} .

Suppose that $\mathbf{X} = \{X_t : t \in [0, \infty)\}$ is a stochastic process on (Ω, \mathcal{F}) that is progressively measurable relative to a complete, right-continuous filtration $\mathfrak{F} = \{\mathcal{F}_t : t \in [0, \infty)\}$. If $A \in \mathcal{S}$ then ρ_A and τ_A are stopping times relative to \mathfrak{F} .

CHAPTER OVERVIEW

3: Distributions

Recall that a *probability distribution* is just another name for a [probability measure](#). Most distributions are associated with [random variables](#), and in fact every distribution *can* be associated with a random variable. In this chapter we explore the basic types of probability distributions (discrete, continuous, mixed), and the ways that distributions can be defined using density functions, distribution functions, and quantile functions. We also study the relationship between the distribution of a random vector and the distributions of its components, conditional distributions, and how the distribution of a random variable changes when the variable is transformed.

In the advanced sections, we study convergence in distribution, one of the most important types of convergence. We also construct the abstract integral with respect to a positive measure and study the basic properties of the integral. This leads in turn to general (signed measures), absolute continuity and singularity, and the existence of density functions. Finally, we study various vector spaces of functions that are defined by integral pro

3.1: Discrete Distributions

Basic Theory

Definitions and Basic Properties

As usual, our starting point is a random experiment modeled by a probability space $(S, \mathcal{S}, \mathbb{P})$. So to review, S is the set of outcomes, \mathcal{S} the collection of events, and \mathbb{P} the probability measure on the sample space (S, \mathcal{S}) . We use the terms *probability measure* and *probability distribution* synonymously in this text. Also, since we use a general definition of random variable, every probability measure can be thought of as the probability distribution of a random variable, so we can always take this point of view if we like. Indeed, most probability measures naturally have random variables associated with them.

Recall that the sample space (S, \mathcal{S}) is *discrete* if S is countable and $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S . In this case, \mathbb{P} is a *discrete distribution* and $(S, \mathcal{S}, \mathbb{P})$ is a *discrete probability space*.

For the remainder of our discussion we assume that $(S, \mathcal{S}, \mathbb{P})$ is a discrete probability space. In the picture below, the blue dots are intended to represent points of positive probability.

Figure 3.1.1: A discrete distribution

It's very simple to describe a discrete probability distribution with the function that assigns probabilities to the individual points in S .

The function f on S defined by $f(x) = \mathbb{P}(\{x\})$ for $x \in S$ is the *probability density function* of \mathbb{P} , and satisfies the following properties:

1. $f(x) \geq 0$, $x \in S$
2. $\sum_{x \in S} f(x) = 1$
3. $\sum_{x \in A} f(x) = \mathbb{P}(A)$ for $A \subseteq S$

Proof

These properties follow from the axioms of a probability measure.

1. $f(x) = \mathbb{P}(\{x\}) \geq 0$ since probabilities are nonnegative.
2. $\sum_{x \in S} f(x) = \sum_{x \in S} \mathbb{P}(\{x\}) = \mathbb{P}(S) = 1$ by the countable additivity axiom.
3. $\sum_{x \in A} f(x) = \sum_{x \in A} \mathbb{P}(\{x\}) = \mathbb{P}(A)$ for $A \subseteq S$ again, by the countable additivity axiom.

Property (c) is particularly important since it shows that a discrete probability distribution is completely determined by its probability density function. Conversely, any function that satisfies properties (a) and (b) can be used to construct a discrete probability distribution on S via property (c).

A nonnegative function f on S that satisfies $\sum_{x \in S} f(x) = 1$ is a (discrete) *probability density function* on S , and then \mathbb{P} defined as follows is a probability measure on S .

$$\mathbb{P}(A) = \sum_{x \in A} f(x), \quad A \subseteq S \quad (3.1.1)$$

Proof

1. $\mathbb{P}(A) = \sum_{x \in A} f(x) \geq 0$ since f is nonnegative.
2. $\mathbb{P}(S) = \sum_{x \in S} f(x) = 1$ by property (b)
3. Suppose that $\{A_i : i \in I\}$ is a countable, disjoint collection of subsets of S , and let $A = \bigcup_{i \in I} A_i$. Then

$$\mathbb{P}(A) = \sum_{x \in A} f(x) = \sum_{i \in I} \sum_{x \in A_i} f(x) = \sum_{i \in I} \mathbb{P}(A_i) \quad (3.1.2)$$

Note that since f is nonnegative, the order of the terms in the sum do not matter.

Technically, f is the density of \mathbb{P} relative to counting measure $\#$ on S . The technicalities are discussed in detail in the advanced section on absolute continuity and density functions.

Figure 3.1.2: A discrete distribution is completely determined by its probability density function.

The set of outcomes S is often a countable subset of some larger set, such as \mathbb{R}^n for some $n \in \mathbb{N}_+$. But not always. We might want to consider a random variable with values in a deck of cards, or a set of words, or some other discrete population of objects. Of course, we can always map a countable set S one-to-one into a Euclidean set, but it might be contrived or unnatural to do so. In any event, if S is a subset of a larger set, we can always extend a probability density function f , if we want, to the larger set by defining $f(x) = 0$ for $x \notin S$. Sometimes this extension simplifies formulas and notation. Put another way, the “set of values” is often a convenience set that includes the points with positive probability, but perhaps other points as well.

Suppose that f is a probability density function on S . Then $\{x \in S : f(x) > 0\}$ is the *support set* of the distribution.

Values of x that maximize the probability density function are important enough to deserve a name.

Suppose again that f is a probability density function on S . An element $x \in S$ that maximizes f is a *mode* of the distribution.

When there is only one mode, it is sometimes used as a measure of the *center* of the distribution.

A discrete probability distribution defined by a probability density function f is equivalent to a *discrete mass distribution*, with total mass 1. In this analogy, S is the (countable) set of point masses, and $f(x)$ is the mass of the point at $x \in S$. Property (c) in (2) above simply means that the mass of a set A can be found by adding the masses of the points in A .

But let's consider a probabilistic interpretation, rather than one from physics. We start with a basic random variable X for an experiment, defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Suppose that X has a discrete distribution on S with probability density function f . So in this setting, $f(x) = \mathbb{P}(X = x)$ for $x \in S$. We create a new, compound experiment by conducting independent repetitions of the original experiment. So in the compound experiment, we have a sequence of independent random variables (X_1, X_2, \dots) each with the same distribution as X ; in statistical terms, we are *sampling* from the distribution of X . Define

$$f_n(x) = \frac{1}{n} \# \{i \in \{1, 2, \dots, n\} : X_i = x\} = \frac{1}{n} \sum_{i=1}^n \mathbf{1}(X_i = x), \quad x \in S \quad (3.1.3)$$

Note that $f_n(x)$ is the *relative frequency* of outcome $x \in S$ in the first n runs. Note also that $f_n(x)$ is a random variable for the compound experiment for each $x \in S$. By the law of large numbers, $f_n(x)$ should converge to $f(x)$, in some sense, as $n \rightarrow \infty$. The function f_n is called the *empirical probability density function*, and it is in fact a (random) probability density function, since it satisfies properties (a) and (b) of (2). Empirical probability density functions are displayed in most of the simulation apps that deal with discrete variables.

It's easy to construct discrete probability density functions from other nonnegative functions defined on a countable set.

Suppose that g is a nonnegative function defined on S , and let

$$c = \sum_{x \in S} g(x) \quad (3.1.4)$$

If $0 < c < \infty$, then the function f defined by $f(x) = \frac{1}{c} g(x)$ for $x \in S$ is a discrete probability density function on S .

Proof

Clearly $f(x) \geq 0$ for $x \in S$. also

$$\sum_{x \in S} f(x) = \frac{1}{c} \sum_{x \in S} g(x) = \frac{c}{c} = 1 \quad (3.1.5)$$

Note that since we are assuming that g is nonnegative, $c = 0$ if and only if $g(x) = 0$ for every $x \in S$. At the other extreme, $c = \infty$ could only occur if S is infinite (and the infinite series diverges). When $0 < c < \infty$ (so that we can construct the probability density function f), c is sometimes called the *normalizing constant*. This result is useful for constructing probability density functions with desired functional properties (domain, shape, symmetry, and so on).

Conditional Densities

Suppose again that X is a random variable on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and that X takes values in our discrete set S . The distribution of X (and hence the probability density function of X) is based on the underlying probability measure on the sample space (Ω, \mathcal{F}) . This measure could be a conditional probability measure, conditioned on a given event $E \in \mathcal{F}$ (with $\mathbb{P}(E) > 0$). The probability density function in this case is

$$f(x | E) = \mathbb{P}(X = x | E), \quad x \in S \quad (3.1.6)$$

Except for notation, no new concepts are involved. Therefore, all results that hold for discrete probability density functions in general have analogies for conditional discrete probability density functions.

For fixed $E \in \mathcal{F}$ with $\mathbb{P}(E) > 0$ the function $x \mapsto f(x | E)$ is a discrete probability density function on S . That is,

1. $f(x | E) \geq 0$ for $x \in S$.
2. $\sum_{x \in S} f(x | E) = 1$
3. $\sum_{x \in A} f(x | E) = \mathbb{P}(X \in A | E)$ for $A \subseteq S$

Proof

This is a consequence of the fact that $A \mapsto \mathbb{P}(A | E)$ is a probability measure on (Ω, \mathcal{F}) . The function $x \mapsto f(x | E)$ plays the same role for the conditional probability measure that f does for the original probability measure \mathbb{P} .

In particular, the event E could be an event defined in terms of the random variable X itself.

Suppose that $B \subseteq S$ and $\mathbb{P}(X \in B) > 0$. The conditional probability density function of X given $X \in B$ is the function on B defined by

$$f(x | X \in B) = \frac{f(x)}{\mathbb{P}(X \in B)} = \frac{f(x)}{\sum_{y \in B} f(y)}, \quad x \in B \quad (3.1.7)$$

Proof

This follows from the previous theorem. $f(x | X \in B) = \mathbb{P}(X = x, X \in B) / \mathbb{P}(X \in B)$. The numerator is $f(x)$ if $x \in B$ and is 0 if $x \notin B$.

Note that the denominator is simply the [normalizing constant](#) for f restricted to B . Of course, $f(x | B) = 0$ for $x \in B^c$.

Conditioning and Bayes' Theorem

Suppose again that X is a random variable defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and that X has a discrete distribution on S , with probability density function f . We assume that $f(x) > 0$ for $x \in S$ so that the distribution has support S . The versions of the law of total probability and Bayes' theorem given in the following theorems follow immediately from the corresponding results in the section on Conditional Probability. Only the notation is different.

Law of Total Probability. If $E \in \mathcal{F}$ is an event then

$$\mathbb{P}(E) = \sum_{x \in S} f(x) \mathbb{P}(E | X = x) \quad (3.1.8)$$

Proof

Note that $\{\{X = x\} : x \in S\}$ is a countable partition of the sample space Ω . That is, these events are disjoint and their union is the entire sample space Ω . Hence

$$\mathbb{P}(E) = \sum_{x \in S} \mathbb{P}(E \cap \{X = x\}) = \sum_{x \in S} \mathbb{P}(X = x) \mathbb{P}(E | X = x) = \sum_{x \in S} f(x) \mathbb{P}(E | X = x) \quad (3.1.9)$$

This result is useful, naturally, when the distribution of X and the conditional probability of E given the values of X are known. When we compute $\mathbb{P}(E)$ in this way, we say that we are *conditioning* on X . Note that $\mathbb{P}(E)$, as expressed by the formula, is a weighted average of $\mathbb{P}(E | X = x)$, with weight factors $f(x)$, over $x \in S$.

Bayes' Theorem. If $E \in \mathcal{F}$ is an event with $\mathbb{P}(E) > 0$ then

$$f(x | E) = \frac{f(x) \mathbb{P}(E | X = x)}{\sum_{y \in S} f(y) \mathbb{P}(E | X = y)}, \quad x \in S \quad (3.1.10)$$

Proof

Note that the numerator of the fraction on the right is $\mathbb{P}(X = x) \mathbb{P}(E | X = x) = \mathbb{P}(\{X = x\} \cap E)$. The denominator is $\mathbb{P}(E)$ by the previous theorem. Hence the ratio is $\mathbb{P}(X = x | E) = f(x | E)$.

Bayes' theorem, named for Thomas Bayes, is a formula for the conditional probability density function of X given E . Again, it is useful when the quantities on the right are known. In the context of Bayes' theorem, the (unconditional) distribution of X is referred to as the *prior* distribution and the conditional distribution as the *posterior* distribution. Note that the denominator in Bayes' formula is $\mathbb{P}(E)$ and is simply the [normalizing constant](#) for the function $x \mapsto f(x) \mathbb{P}(E | X = x)$.

Examples and Special Cases

We start with some simple (albeit somewhat artificial) discrete distributions. After that, we study three special parametric models—the [discrete uniform distribution](#), [hypergeometric distributions](#), and [Bernoulli trials](#). These models are very important, so when working the computational problems that follow, try to see if the problem fits one of these models. As always, be sure to try the problems yourself before looking at the answers and proofs in the text.

Simple Discrete Distributions

Let g be the function defined by $g(n) = n(10 - n)$ for $n \in \{1, 2, \dots, 9\}$.

1. Find the probability density function f that is [proportional](#) to g as in .
2. Sketch the graph of f and find the mode of the distribution.
3. Find $\mathbb{P}(3 \leq N \leq 6)$ where N has probability density function f .

Answer

1. $f(n) = \frac{1}{165} n(10 - n)$ for $n \in \{1, 2, \dots, 9\}$
2. mode $n = 5$
3. $\frac{94}{165}$

Let g be the function defined by $g(n) = n^2(10 - n)$ for $n \in \{1, 2, \dots, 10\}$.

1. Find the probability density function f that is [proportional](#) to g .
2. Sketch the graph of f and find the mode of the distribution.
3. Find $\mathbb{P}(3 \leq N \leq 6)$ where N has probability density function f .

Answer

1. $f(n) = \frac{1}{825} n^2(10 - n)$ for $n \in \{1, 2, \dots, 9\}$
2. mode $n = 7$
3. $\frac{428}{825}$

Let g be the function defined by $g(x, y) = x + y$ for $(x, y) \in \{1, 2, 3\}^2$.

1. Sketch the domain of g .

2. Find the probability density function f that is **proportional** to g .
3. Find the mode of the distribution.
4. Find $\mathbb{P}(X > Y)$ where (X, Y) has probability density function f .

Answer

1. $f(x, y) = \frac{1}{36}(x + y)$ for $(x, y) \in \{1, 2, 3\}^2$
2. mode $(3, 3)$
3. $\frac{2}{9}$

Let g be the function defined by $g(x, y) = xy$ for $(x, y) \in \{(1, 1), (1, 2), (1, 3), (2, 2), (2, 3), (3, 3)\}$

1. Sketch the domain of g .
2. Find the probability density function f that is **proportional** to g .
3. Find the mode of the distribution.
4. Find $\mathbb{P}[(X, Y) \in \{(1, 2), (1, 3), (2, 2), (2, 3)\}]$ where (X, Y) has probability density function f .

Answer

1. $f(x, y) = \frac{1}{25}xy$ for $(x, y) \in \{(1, 1), (1, 2), (1, 3), (2, 2), (2, 3), (3, 3)\}$
2. mode $(3, 3)$
3. $\frac{3}{5}$

Consider the following game: An urn initially contains one red and one green ball. A ball is selected at random, and if the ball is green, the game is over. If the ball is red, the ball is returned to the urn, another red ball is added, and the game continues. At each stage, a ball is selected at random, and if the ball is green, the game is over. If the ball is red, the ball is returned to the urn, another red ball is added, and the game continues. Let X denote the length of the game (that is, the number of selections required to obtain a green ball). Find the probability density function of X .

Solution

Note that X takes values in \mathbb{N}_+ . Using the multiplication rule for conditional probabilities, the PDF f of X is given by

$$f(1) = \frac{1}{2} = \frac{1}{1 \cdot 2}, \quad f(2) = \frac{1}{2} \cdot \frac{1}{3} = \frac{1}{2 \cdot 3}, \quad f(3) = \frac{1}{2} \cdot \frac{2}{3} \cdot \frac{1}{4} = \frac{1}{3 \cdot 4} \quad (3.1.11)$$

and in general, $f(x) = \frac{1}{x(x+1)}$ for $x \in \mathbb{N}_+$. By partial fractions, $f(x) = \frac{1}{x} - \frac{1}{x+1}$ for $x \in \mathbb{N}_+$ so we can check that f is a valid PDF:

$$\sum_{x=1}^{\infty} \left(\frac{1}{x} - \frac{1}{x+1} \right) = \lim_{n \rightarrow \infty} \sum_{x=1}^n \left(\frac{1}{x} - \frac{1}{x+1} \right) = \lim_{n \rightarrow \infty} \left(1 - \frac{1}{n+1} \right) = 1 \quad (3.1.12)$$

Discrete Uniform Distributions

An element X is chosen at random from a finite set S . The distribution of X is the *discrete uniform distribution* on S .

1. X has probability density function f given by $f(x) = 1/\#(S)$ for $x \in S$.
2. $\mathbb{P}(X \in A) = \#(A)/\#(S)$ for $A \subseteq S$.

Proof

The phrase *at random* means that all outcomes are equally likely.

Many random variables that arise in sampling or combinatorial experiments are transformations of uniformly distributed variables. The next few exercises review the standard methods of sampling from a finite population. The parameters m and n are positive integers.

Suppose that n elements are chosen at random, with replacement from a set D with m elements. Let \mathbf{X} denote the ordered sequence of elements chosen. Then \mathbf{X} is uniformly distributed on the Cartesian power set $S = D^n$, and has probability density function f given by

$$f(\mathbf{x}) = \frac{1}{m^n}, \quad \mathbf{x} \in S \quad (3.1.13)$$

Proof

Recall that $\#(D^n) = m^n$.

Suppose that n elements are chosen at random, without replacement from a set D with m elements (so $n \leq m$). Let \mathbf{X} denote the ordered sequence of elements chosen. Then \mathbf{X} is uniformly distributed on the set S of permutations of size n chosen from D , and has probability density function f given by

$$f(\mathbf{x}) = \frac{1}{m^{(n)}}, \quad \mathbf{x} \in S \quad (3.1.14)$$

Proof

Recall that the number of permutations of size n from D is $m^{(n)}$.

Suppose that n elements are chosen at random, without replacement, from a set D with m elements (so $n \leq m$). Let \mathbf{W} denote the unordered set of elements chosen. Then \mathbf{W} is uniformly distributed on the set T of combinations of size n chosen from D , and has probability density function f given by

$$f(\mathbf{w}) = \frac{1}{\binom{m}{n}}, \quad \mathbf{w} \in T \quad (3.1.15)$$

Proof

Recall that the number of combinations of size n from D is $\binom{m}{n}$.

Suppose that X is uniformly distributed on a finite set S and that B is a nonempty subset of S . Then the conditional distribution of X given $X \in B$ is uniform on B .

Proof

From (7), the conditional probability density function of X given $X \in B$ is

$$f(x | B) = \frac{f(x)}{\mathbb{P}(X \in B)} = \frac{1/\#(S)}{\#(B)/\#(S)} = \frac{1}{\#(B)}, \quad x \in B \quad (3.1.16)$$

Hypergeometric Models

Suppose that a *dichotomous* population consists of m objects of two different types: r of the objects are type 1 and $m - r$ are type 0. Here are some typical examples:

- The objects are persons, each either *male* or *female*.
- The objects are voters, each either a *democrat* or a *republican*.
- The objects are devices of some sort, each either *good* or *defective*.
- The objects are fish in a lake, each either *tagged* or *untagged*.
- The objects are balls in an urn, each either *red* or *green*.

A sample of n objects is chosen at random (without replacement) from the population. Recall that this means that the samples, either ordered or unordered are equally likely. Note that this probability model has three parameters: the population size m , the number of type 1 objects r , and the sample size n . Each is a nonnegative integer with $r \leq m$ and $n \leq m$. Now, suppose that we keep track of order, and let X_i denote the type of the i th object chosen, for $i \in \{1, 2, \dots, n\}$. Thus, X_i is an indicator variable (that is, a variable that just takes values 0 and 1).

$\mathbf{X} = (X_1, X_2, \dots, X_n)$ has probability density function f given by

$$f(x_1, x_2, \dots, x_n) = \frac{r^{(y)}(m-r)^{(n-y)}}{m^{(n)}}, \quad (x_1, x_2, \dots, x_n) \in \{0, 1\}^n \text{ where } y = x_1 + x_2 + \dots + x_n \quad (3.1.17)$$

Proof

Recall again that the ordered samples are equally likely, and there are $m^{(n)}$ such samples. The number of ways to select the y type 1 objects and place them in the positions where $x_i = 1$ is $r^{(y)}$. The number of ways to select the $n - y$ type 0 objects and place them in the positions where $x_i = 0$ is $(m - r)^{(n-y)}$. Thus the result follows from the multiplication principle.

Note that the value of $f(x_1, x_2, \dots, x_n)$ depends only on $y = x_1 + x_2 + \dots + x_n$, and hence is unchanged if (x_1, x_2, \dots, x_n) is permuted. This means that (X_1, X_2, \dots, X_n) is exchangeable. In particular, the distribution of X_i is the same as the distribution of X_1 , so $\mathbb{P}(X_i = 1) = \frac{r}{m}$. Thus, the variables are *identically distributed*. Also the distribution of (X_i, X_j) is the same as the distribution of (X_1, X_2) , so $\mathbb{P}(X_i = 1, X_j = 1) = \frac{r(r-1)}{m(m-1)}$. Thus, X_i and X_j are not independent, and in fact are negatively correlated.

Now let Y denote the number of type 1 objects in the sample. Note that $Y = \sum_{i=1}^n X_i$. Any counting variable can be written as a sum of indicator variables.

Y has probability density function g given by.

$$g(y) = \frac{\binom{r}{y} \binom{m-r}{n-y}}{\binom{m}{n}}, \quad y \in \{0, 1, \dots, n\} \quad (3.1.18)$$

1. $g(y-1) < g(y)$ if and only if $y < t$ where $t = (r+1)(n+1)/(m+2)$.
2. If t is not a positive integer, there is a single mode at $\lfloor t \rfloor$.
3. If t is a positive integer, then there are two modes, at $t-1$ and t .

Proof

Recall again that the unordered samples of size n chosen from the population are equally likely. By the multiplication principle, the number of samples with exactly y type 1 objects and $n - y$ type 0 objects is $\binom{m}{y} \binom{m-r}{n-y}$. The total number of samples is $\binom{m}{n}$.

1. Note that $g(y-1) < g(y)$ if and only if $\binom{r}{y-1} \binom{m-r}{n+1-y} < \binom{r}{y} \binom{m-r}{n-y}$. Writing the binomial coefficients in terms of factorials and canceling terms gives $g(y-1) < g(y)$ if and only if $y < t$, where t is given above.
2. By the same argument, $f(y-1) = f(y)$ if and only if $y = t$. If t is not an integer then this cannot happen. Letting $z = \lfloor t \rfloor$, it follows from (a) that $g(y) < g(z)$ if $y < z$ or $y > z$.
3. If t is a positive integer, then by (b), $g(t-1) = g(t)$ and by (a) $g(y) < g(t-1)$ if $y < t-1$ and $g(y) < g(t)$ if $y > t$.

The distribution defined by the probability density function in the last result is the *hypergeometric distributions* with parameters m , r , and n . The term *hypergeometric* comes from a certain class of special functions, but is not particularly helpful in terms of remembering the model. Nonetheless, we are stuck with it. The set of values $\{0, 1, \dots, n\}$ is a *convenience set*: it contains all of the values that have positive probability, but depending on the parameters, some of the values may have probability 0. Recall our convention for binomial coefficients: for $j, k \in \mathbb{N}_+$, $\binom{k}{j} = 0$ if $j > k$. Note also that the hypergeometric distribution is unimodal: the probability density function increases and then decreases, with either a single mode or two adjacent modes.

We can extend the hypergeometric model to a population of three types. Thus, suppose that our population consists of m objects; r of the objects are type 1, s are type 2, and $m - r - s$ are type 0. Here are some examples:

- The objects are voters, each a *democrat*, a *republican*, or an *independent*.
- The objects are cicadas, each one of three species: *tredecula*, *tredecassini*, or *tredecim*.
- The objects are peaches, each classified as *small*, *medium*, or *large*.
- The objects are faculty members at a university, each an *assistant professor*, or an *associate professor*, or a *full professor*.

Once again, a sample of n objects is chosen at random (without replacement). The probability model now has four parameters: the population size m , the type sizes r and s , and the sample size n . All are nonnegative integers with $r + s \leq m$ and $n \leq m$. Moreover, we now need two random variables to keep track of the counts for the three types in the sample. Let Y denote the number of type 1 objects in the sample and Z the number of type 2 objects in the sample.

(Y, Z) has probability density function h given by

$$h(y, z) = \frac{\binom{r}{y} \binom{s}{z} \binom{m-r-s}{n-y-z}}{\binom{m}{n}}, \quad (y, z) \in \{0, 1, \dots, n\}^2 \text{ with } y + z \leq n \quad (3.1.19)$$

Proof

Once again, by the multiplication principle, the number of samples of size n from the population with exactly y type 1 objects, z type 2 objects, and $n - y - z$ type 0 objects is $\binom{r}{y} \binom{s}{z} \binom{m-r-s}{n-y-z}$. The total number of samples of size n is $\binom{m}{n}$.

The distribution defined by the density function in the last exercise is the *bivariate hypergeometric distribution* with parameters m , r , s , and n . Once again, the domain given is a convenience set; it includes the set of points with positive probability, but depending on the parameters, may include points with probability 0. Clearly, the same general pattern applies to populations with even more types. However, because of all of the parameters, the formulas are not worth remembering in detail; rather, just note the pattern, and remember the combinatorial meaning of the binomial coefficient. The hypergeometric model will be revisited later in this chapter, in the section on joint distributions and in the section on conditional distributions. The hypergeometric distribution and the multivariate hypergeometric distribution are studied in detail in the chapter on Finite Sampling Models. This chapter contains a variety of distributions that are based on discrete uniform distributions.

Bernoulli Trials

A *Bernoulli trials sequence* is a sequence (X_1, X_2, \dots) of independent, identically distributed indicator variables. Random variable X_i is the outcome of trial i , where in the usual terminology of reliability, 1 denotes *success* while 0 denotes *failure*. The process is named for Jacob Bernoulli. Let $p = \mathbb{P}(X_i = 1) \in [0, 1]$ denote the success parameter of the process. Note that the indicator variables in the [hypergeometric model](#) satisfy one of the assumptions of Bernoulli trials (identical distributions) but not the other (independence).

$\mathbf{X} = (X_1, X_2, \dots, X_n)$ has probability density function f given by

$$f(x_1, x_2, \dots, x_n) = p^y (1-p)^{n-y}, \quad (x_1, x_2, \dots, x_n) \in \{0, 1\}^n, \text{ where } y = x_1 + x_2 + \dots + x_n \quad (3.1.20)$$

Proof

By definition, $\mathbb{P}(X_i = 1) = p$ and $\mathbb{P}(X_i = 0) = 1 - p$. Equivalently, $\mathbb{P}(X_i = x) = p^x (1-p)^{1-x}$ for $x \in \{0, 1\}$. The formula for f then follows by independence.

Now let Y denote the number of successes in the first n trials. Note that $Y = \sum_{i=1}^n X_i$, so we see again that a complicated random variable can be written as a sum of simpler ones. In particular, a counting variable can always be written as a sum of indicator variables.

Y has probability density function g given by

$$g(y) = \binom{n}{y} p^y (1-p)^{n-y}, \quad y \in \{0, 1, \dots, n\} \quad (3.1.21)$$

1. $g(y-1) < g(y)$ if and only if $y < t$, where $t = (n+1)p$.
2. If t is not a positive integer, there is a single mode at $\lfloor t \rfloor$.
3. If t is a positive integer, then there are two modes, at $t-1$ and t .

Proof

From the previous result, any particular sequence of n Bernoulli trials with y successes and $n-y$ failures has probability $p^y (1-p)^{n-y}$. The number of such sequences is $\binom{n}{y}$, so the formula for g follows by the additivity of probability.

1. Note that $g(y-1) < g(y)$ if and only if $\binom{n}{y-1} p^{y-1} (1-p)^{n-y+1} < \binom{n}{y} p^y (1-p)^{n-y}$. Writing the binomial coefficients in terms of factorials and canceling gives $g(y-1) < g(y)$ if and only if $y < t$ where $t = (n+1)p$.
2. By the same argument, $g(y-1) = g(y)$ if and only if $y = t$. If t is not an integer, this cannot happen. Letting $z = \lfloor t \rfloor$, it follows from (a) that $g(y) < g(z)$ if $y < z$ or $y > z$.
3. If t is a positive integer, then by (b), $g(t-1) = g(t)$ and by (a) $g(y) < g(t-1)$ if $y < t-1$ and $g(y) < g(t)$ if $y > t$.

The distribution defined by the probability density function in the last theorem is called the *binomial distribution* with parameters n and p . The distribution is unimodal: the probability density function at first increases and then decreases, with either a single mode or two adjacent modes. The binomial distribution is studied in detail in the chapter on Bernoulli Trials.

Suppose that $p > 0$ and let N denote the trial number of the first success. Then N has probability density function h given by

$$h(n) = (1-p)^{n-1}p, \quad n \in \mathbb{N}_+ \quad (3.1.22)$$

The probability density function h is decreasing and the mode is $n = 1$.

Proof

For $n \in \mathbb{N}_+$, the event $\{N = n\}$ means that the first $n - 1$ trials were failures and trial n was a success. Each trial results in failure with probability $1 - p$ and success with probability p , and the trials are independent, so $\mathbb{P}(N = n) = (1 - p)^{n-1}p$. Using geometric series, we can check that

$$\sum_{n=1}^{\infty} h(n) = \sum_{n=1}^{\infty} p(1-p)^{n-1} = \frac{p}{1-(1-p)} = 1 \quad (3.1.23)$$

The distribution defined by the probability density function in the last exercise is the *geometric distribution* on \mathbb{N}_+ with parameter p . The geometric distribution is studied in detail in the chapter on Bernoulli Trials.

Sampling Problems

In the following exercises, be sure to check if the problem fits one of the general models above.

An urn contains 30 red and 20 green balls. A sample of 5 balls is selected at random, without replacement. Let Y denote the number of red balls in the sample.

1. Compute the probability density function of Y explicitly and identify the distribution by name and parameter values.
2. Graph the probability density function and identify the mode(s).
3. Find $\mathbb{P}(Y > 3)$.

Answer

1. $f(0) = 0.0073$, $f(1) = 0.0686$, $f(2) = 0.2341$, $f(3) = 0.3641$, $f(4) = 0.2587$, $f(5) = 0.0673$ Hypergeometric with $m = 50$, $r = 30$, $n = 5$
2. mode: $y = 3$
3. $\mathbb{P}(Y > 3) = 0.3260$

In the ball and urn experiment, select sampling without replacement and set $m = 50$, $r = 30$, and $n = 5$. Run the experiment 1000 times and note the agreement between the empirical density function of Y and the probability density function.

An urn contains 30 red and 20 green balls. A sample of 5 balls is selected at random, *with* replacement. Let Y denote the number of red balls in the sample.

1. Compute the probability density function of Y explicitly and identify the distribution by name and parameter values.
2. Graph the probability density function and identify the mode(s).
3. Find $\mathbb{P}(Y > 3)$.

Answer

1. $f(0) = 0.0102$, $f(1) = 0.0768$, $f(2) = 0.2304$, $f(3) = 0.3456$, $f(4) = 0.2592$, $f(5) = 0.0778$ Binomial with $n = 5$, $p = 3/5$
2. mode: $y = 3$
3. $\mathbb{P}(Y > 3) = 0.3370$

In the ball and urn experiment, select sampling with replacement and set $m = 50$, $r = 30$, and $n = 5$. Run the experiment 1000 times and note the agreement between the empirical density function of Y and the probability density function.

A group of voters consists of 50 democrats, 40 republicans, and 30 independents. A sample of 10 voters is chosen at random, without replacement. Let X denote the number of democrats in the sample and Y the number of republicans in the sample.

1. Give the probability density function of X .
2. Give the probability density function of Y .
3. Give the probability density function of (X, Y) .
4. Find the probability that the sample has at least 4 democrats and at least 4 republicans.

Answer

1. $g(x) = \frac{\binom{50}{x} \binom{70}{10-x}}{\binom{120}{10}}$ for $x \in \{0, 1, \dots, 10\}$ This is the hypergeometric distribution with parameters $m = 120$, $r = 50$ and $n = 10$.
2. $h(y) = \frac{\binom{40}{y} \binom{80}{10-y}}{\binom{120}{10}}$ for $y \in \{0, 1, \dots, 10\}$ This is the hypergeometric distribution with parameters $m = 120$, $r = 40$ and $n = 10$.
3. $f(x, y) = \frac{\binom{50}{x} \binom{40}{y} \binom{30}{10-x-y}}{\binom{120}{10}}$ for $(x, y) \in \{0, 1, \dots, 10\}^2$ with $x + y \leq 10$. This is the bivariate hypergeometric distribution with parameters $m = 120$, $r = 50$, $s = 40$ and $n = 10$.
4. $\mathbb{P}(X \geq 4, Y \geq 4) = \frac{15\,137\,200}{75\,597\,113} \approx 0.200$

The Math Club at Enormous State University (ESU) has 20 freshmen, 40 sophomores, 30 juniors, and 10 seniors. A committee of 8 club members is chosen at random, without replacement to organize π -day activities. Let X denote the number of freshman in the sample, Y the number of sophomores, and Z the number of juniors.

1. Give the probability density function of X .
2. Give the probability density function of Y .
3. Give the probability density function of Z .
4. Give the probability density function of (X, Y) .
5. Give the probability density function of (X, Y, Z) .
6. Find the probability that the committee has no seniors.

Answer

1. $f_X(x) = \frac{\binom{20}{x} \binom{80}{8-x}}{\binom{100}{8}}$ for $x \in \{0, 1, \dots, 8\}$ This is the hypergeometric distribution with parameters $m = 100$, $r = 20$, and $n = 8$.
2. $f_Y(y) = \frac{\binom{40}{y} \binom{60}{8-y}}{\binom{100}{8}}$ for $y \in \{0, 1, \dots, 8\}$ This is the hypergeometric distribution with parameters $m = 100$, $r = 40$, and $n = 8$.
3. $f_Z(z) = \frac{\binom{30}{z} \binom{70}{8-z}}{\binom{100}{8}}$ for $z \in \{0, 1, \dots, 8\}$ This is the hypergeometric distribution with parameters $m = 100$, $r = 30$, and $n = 8$.
4. $f_{X,Y}(x, y) = \frac{\binom{20}{x} \binom{40}{y} \binom{40}{8-x-y}}{\binom{100}{8}}$ for $(x, y) \in \{0, 1, \dots, 8\}^2$ with $x + y \leq 8$. This is the bivariate hypergeometric distribution with parameters $m = 100$, $r = 20$, $s = 40$ and $n = 8$.
5. $f_{X,Y,Z}(x, y, z) = \frac{\binom{20}{x} \binom{40}{y} \binom{30}{z} \binom{10}{8-x-y-z}}{\binom{100}{8}}$ for $(x, y, z) \in \{0, 1, \dots, 8\}^3$ with $x + y + z \leq 8$. This is the tri-variate hypergeometric distribution with parameters $m = 100$, $r = 20$, $s = 40$, $t = 30$, and $n = 8$.
6. $\mathbb{P}(X + Y + Z = 8) = \frac{156\,597\,013}{275\,935\,140} \approx 0.417$

Coins and Dice

Suppose that a coin with probability of heads p is tossed repeatedly, and the sequence of heads and tails is recorded.

1. Identify the underlying probability model by name and parameter.
2. Let Y denote the number of heads in the first n tosses. Give the probability density function of Y and identify the distribution by name and parameters.
3. Let N denote the number of tosses needed to get the first head. Give the probability density function of N and identify the distribution by name and parameter.

Answer

1. Bernoulli trials with success parameter p .
2. $f(k) = \binom{n}{k} p^k (1-p)^{n-k}$ for $k \in \{0, 1, \dots, n\}$. This is the binomial distribution with trial parameter n and success parameter p .
3. $g(n) = p(1-p)^{n-1}$ for $n \in \mathbb{N}_+$. This is the geometric distribution with success parameter p .

Suppose that a coin with probability of heads $p = 0.4$ is tossed 5 times. Let Y denote the number of heads.

1. Compute the probability density function of Y explicitly.
2. Graph the probability density function and identify the mode.
3. Find $\mathbb{P}(Y > 3)$.

Answer

1. $f(0) = 0.0778$ $f(1) = 0.2592$ $f(2) = 0.3456$ $f(3) = 0.2304$ $f(4) = 0.0768$ $f(5) = 0.0102$
2. mode: $k = 2$
3. $\mathbb{P}(Y > 3) = 0.0870$

In the binomial coin experiment, set $n = 5$ and $p = 0.4$. Run the experiment 1000 times and compare the empirical density function of Y with the probability density function.

Suppose that a coin with probability of heads $p = 0.2$ is tossed until heads occurs. Let N denote the number of tosses.

1. Find the probability density function of N .
2. Find $\mathbb{P}(N \leq 5)$.

Answer

1. $f(n) = (0.8)^{n-1} 0.2$ for $n \in \mathbb{N}_+$
2. $\mathbb{P}(N \leq 5) = 0.67232$

In the negative binomial experiment, set $k = 1$ and $p = 0.2$. Run the experiment 1000 times and compare the empirical density function with the probability density function.

Suppose that two fair, standard dice are tossed and the sequence of scores (X_1, X_2) recorded. Let $Y = X_1 + X_2$ denote the sum of the scores, $U = \min\{X_1, X_2\}$ the minimum score, and $V = \max\{X_1, X_2\}$ the maximum score.

1. Find the probability density function of (X_1, X_2) . Identify the distribution by name.
2. Find the probability density function of Y .
3. Find the probability density function of U .
4. Find the probability density function of V .
5. Find the probability density function of (U, V) .

Answer

We denote the PDFs by f , g , h_1 , h_2 , and h respectively.

1. $f(x_1, x_2) = \frac{1}{36}$ for $(x_1, x_2) \in \{1, 2, 3, 4, 5, 6\}^2$. This is the uniform distribution on $\{1, 2, 3, 4, 5, 6\}^2$.
2. $g(2) = g(12) = \frac{1}{36}$, $g(3) = g(11) = \frac{2}{36}$, $g(4) = g(10) = \frac{3}{36}$, $g(5) = g(9) = \frac{4}{36}$, $g(6) = g(8) = \frac{5}{36}$, $g(7) = \frac{6}{36}$
3. $h_1(1) = \frac{11}{36}$, $h_1(2) = \frac{9}{36}$, $h_1(3) = \frac{7}{36}$, $h_1(4) = \frac{5}{36}$, $h_1(5) = \frac{3}{36}$, $h_1(6) = \frac{1}{36}$
4. $h_2(1) = \frac{1}{36}$, $h_2(2) = \frac{3}{36}$, $h_2(3) = \frac{5}{36}$, $h_2(4) = \frac{7}{36}$, $h_2(5) = \frac{9}{36}$, $h_2(6) = \frac{11}{36}$
5. $h(u, v) = \frac{2}{36}$ if $u < v$, $h(u, v) = \frac{1}{36}$ if $u = v$ where $(u, v) \in \{1, 2, 3, 4, 5, 6\}^2$ with $u \leq v$

Note that (U, V) in the last exercise could serve as the outcome of the experiment that consists of throwing two standard dice if we did not bother to record order. Note from the previous exercise that this random vector does not have a uniform distribution when the dice are fair. The mistaken idea that this vector *should* have the uniform distribution was the cause of difficulties in the early development of probability.

In the dice experiment, select $n = 2$ fair dice. Select the following random variables and note the shape and location of the probability density function. Run the experiment 1000 times. For each of the following variables, compare the empirical density function with the probability density function.

1. Y , the sum of the scores.
2. U , the minimum score.
3. V , the maximum score.

In the die-coin experiment, a fair, standard die is rolled and then a fair coin is tossed the number of times showing on the die. Let N denote the die score and Y the number of heads.

1. Find the probability density function of N . Identify the distribution by name.
2. Find the probability density function of Y .

Answer

1. $g(n) = \frac{1}{6}$ for $n \in \{1, 2, 3, 4, 5, 6\}$ This is the uniform distribution on $\{1, 2, 3, 4, 5, 6\}$
2. $h(0) = \frac{63}{384}$, $h(1) = \frac{120}{384}$, $h(2) = \frac{90}{384}$, $h(3) = \frac{64}{384}$, $h(4) = \frac{29}{384}$, $h(5) = \frac{8}{384}$, $h(6) = \frac{1}{384}$

Run the die-coin experiment 1000 times. For the number of heads, compare the empirical density function with the probability density function.

Suppose that a bag contains 12 coins: 5 are fair, 4 are biased with probability of heads $\frac{1}{3}$; and 3 are two-headed. A coin is chosen at random from the bag and tossed 5 times. Let V denote the probability of heads of the selected coin and let Y denote the number of heads.

1. Find the probability density function of V .
2. Find the probability density function of Y .

Answer

1. $g(1/2) = 5/12$, $g(1/3) = 4/12$, $g(1) = 3/12$
2. $h(0) = 5311/93312$, $h(1) = 16315/93312$, $h(2) = 22390/93312$, $h(3) = 17270/93312$, $h(4) = 7355/93312$, $h(5) = 24671/93312$

Compare the [die-coin experiment](#) with the [bag of coins experiment](#). In the first experiment, we toss a coin with a *fixed* probability of heads a *random* number of times. In second experiment, we effectively toss a coin with a *random* probability of heads a *fixed* number of times. In both cases, we can think of starting with a binomial distribution and *randomizing* one of the parameters.

In the coin-die experiment, a fair coin is tossed. If the coin lands tails, a fair die is rolled. If the coin lands heads, an ace-six flat die is tossed (faces 1 and 6 have probability $\frac{1}{4}$ each, while faces 2, 3, 4, 5 have probability $\frac{1}{8}$ each). Find the probability density function of the die score Y .

Answer

$$f(y) = 5/24 \text{ for } y \in \{1, 6\}, f(y) = 7/24 \text{ for } y \in \{2, 3, 4, 5\}$$

Run the coin-die experiment 1000 times, with the settings in the previous exercise. Compare the empirical density function with the probability density function.

Suppose that a standard die is thrown 10 times. Let Y denote the number of times an ace or a six occurred. Give the probability density function of Y and identify the distribution by name and parameter values in each of the following cases:

1. The die is fair.

2. The die is an ace-six flat.

Answer

1. $f(k) = \binom{10}{k} \left(\frac{1}{3}\right)^k \left(\frac{2}{3}\right)^{10-k}$ for $k \in \{0, 1, \dots, 10\}$. This is the binomial distribution with trial parameter $n = 10$ and success parameter $p = \frac{1}{3}$
2. $f(k) = \binom{10}{k} \left(\frac{1}{2}\right)^{10}$ for $k \in \{0, 1, \dots, 10\}$. This is the binomial distribution with trial parameter $n = 10$ and success parameter $p = \frac{1}{2}$

Suppose that a standard die is thrown until an ace or a six occurs. Let N denote the number of throws. Give the probability density function of N and identify the distribution by name and parameter values in each of the following cases:

1. The die is fair.
2. The die is an ace-six flat.

Answer

1. $g(n) = \left(\frac{2}{3}\right)^{n-1} \frac{1}{3}$ for $n \in \mathbb{N}_+$. This is the geometric distribution with success parameter $p = \frac{1}{3}$
2. $g(n) = \left(\frac{1}{2}\right)^n$ for $n \in \mathbb{N}_+$. This is the geometric distribution with success parameter $p = \frac{1}{2}$

Fred and Wilma takes turns tossing a coin with probability of heads $p \in (0, 1)$: Fred first, then Wilma, then Fred again, and so forth. The first person to toss heads wins the game. Let N denote the number of tosses, and W the event that Wilma wins.

1. Give the probability density function of N and identify the distribution by name.
2. Compute $\mathbb{P}(W)$ and sketch the graph of this probability as a function of p .
3. Find the conditional probability density function of N given W .

Answer

1. $f(n) = p(1-p)^{n-1}$ for $n \in \mathbb{N}_+$. This is the geometric distribution with success parameter p .
2. $\mathbb{P}(W) = \frac{1-p}{2-p}$
3. $f(n | W) = p(2-p)(1-p)^{n-2}$ for $n \in \{2, 4, \dots\}$

The *alternating coin tossing game* is studied in more detail in the section on The Geometric Distribution in the chapter on Bernoulli trials.

Suppose that k players each have a coin with probability of heads p , where $k \in \{2, 3, \dots\}$ and where $p \in (0, 1)$.

1. Suppose that the players toss their coins at the same time. Find the probability that there is an *odd man*, that is, one player with a different outcome than all the rest.
2. Suppose now that the players repeat the procedure in part (a) until there is an odd man. Find the probability density function of N , the number of rounds played, and identify the distribution by name.

Answer

1. The probability is $2p(1-p)$ if $k = 2$, and is $kp(1-p)^{k-1} + kp^{k-1}(1-p)$ if $k > 2$.
2. Let r_k denote the probability in part (a). N has PDF $f(n) = (1-r_k)^{n-1} r_k$ for $n \in \mathbb{N}$, and has the geometric distribution with parameter r_k .

The *odd man out* game is treated in more detail in the section on the Geometric Distribution in the chapter on Bernoulli Trials.

Cards

Recall that a *poker hand* consists of 5 cards chosen at random and without replacement from a standard deck of 52 cards. Let X denote the number of spades in the hand and Y the number of hearts in the hand. Give the probability density function of each of the following random variables, and identify the distribution by name:

1. X
2. Y
3. (X, Y)

Answer

1. $g(x) = \frac{\binom{13}{x} \binom{39}{5-x}}{\binom{52}{5}}$ for $x \in \{0, 1, 2, 3, 4, 5\}$ This is the hypergeometric distribution with population size $m = 52$, type parameter $r = 13$, and sample size $n = 5$
2. $h(y) = \frac{\binom{13}{y} \binom{39}{5-y}}{\binom{52}{5}}$ for $y \in \{0, 1, 2, 3, 4, 5\}$ This is the same hypergeometric distribution as in part (a).
3. $f(x, y) = \frac{\binom{13}{x} \binom{13}{y} \binom{26}{5-x-y}}{\binom{52}{5}}$ for $(x, y) \in \{0, 1, 2, 3, 4, 5\}^2$ with $x + y \leq 5$. This is a bivariate hypergeometric distribution.

Recall that a *bridge hand* consists of 13 cards chosen at random and without replacement from a standard deck of 52 cards. An *honor card* is a card of denomination ace, king, queen, jack or 10. Let N denote the number of honor cards in the hand.

1. Find the probability density function of N and identify the distribution by name.
2. Find the probability that the hand has no honor cards. A hand of this kind is known as a Yarborough, in honor of Second Earl of Yarborough.

Answer

1. $f(n) = \frac{\binom{20}{n} \binom{32}{13-n}}{\binom{52}{13}}$ for $n \in \{0, 1, \dots, 13\}$ This is the hypergeometric distribution with population size $m = 52$, type parameter $r = 20$ and sample size $n = 13$.
2. 0.00547

In the most common *high card point system* in bridge, an ace is worth 4 points, a king is worth 3 points, a queen is worth 2 points, and a jack is worth 1 point. Find the probability density function of V , the point value of a random bridge hand.

Reliability

Suppose that in a batch of 500 components, 20 are defective and the rest are good. A sample of 10 components is selected at random and tested. Let X denote the number of defectives in the sample.

1. Find the probability density function of X and identify the distribution by name and parameter values.
2. Find the probability that the sample contains at least one defective component.

Answer

1. $f(x) = \frac{\binom{20}{x} \binom{480}{10-x}}{\binom{500}{10}}$ for $x \in \{0, 1, \dots, 10\}$ This is the hypergeometric distribution with population size $m = 500$, type parameter $r = 20$, and sample size $n = 10$.
2. $\mathbb{P}(X \geq 1) = 1 - \frac{\binom{480}{10}}{\binom{500}{10}} \approx 0.3377$

A plant has 3 assembly lines that produce a certain type of component. Line 1 produces 50% of the components and has a defective rate of 4%; line 2 produces 30% of the components and has a defective rate of 5%; line 3 produces 20% of the components and has a defective rate of 1%. A component is chosen at random from the plant and tested.

1. Find the probability that the component is defective.
2. Given that the component is defective, find the conditional probability density function of the line that produced the component.

Answer

Let D the event that the item is defective, and $f(\cdot | D)$ the PDF of the line number given D .

1. $\mathbb{P}(D) = 0.037$
2. $f(1 | D) = 0.541, f(2 | D) = 0.405, f(3 | D) = 0.054$

Recall that in the standard model of *structural reliability*, a system consists of n components, each of which, independently of the others, is either working or failed. Let X_i denote the state of component i , where 1 means working and 0 means failed. Thus, the state vector is $\mathbf{X} = (X_1, X_2, \dots, X_n)$. The system as a whole is also either working or failed, depending only on the states of the components. Thus, the state of the system is an indicator random variable $U = u(\mathbf{X})$ that depends on the states of the components according to a *structure function* $u : \{0, 1\}^n \rightarrow \{0, 1\}$. In a *series system*, the system works if and only if every component works. In a *parallel system*, the system works if and only if at least one component works. In a *k out of n system*, the system works if and only if at least k of the n components work.

The *reliability* of a device is the probability that it is working. Let $p_i = \mathbb{P}(X_i = 1)$ denote the reliability of component i , so that $\mathbf{p} = (p_1, p_2, \dots, p_n)$ is the vector of component reliabilities. Because of the independence assumption, the system reliability depends only on the component reliabilities, according to a *reliability function* $r(\mathbf{p}) = \mathbb{P}(U = 1)$. Note that when all component reliabilities have the same value p , the states of the components form a sequence of n [Bernoulli trials](#). In this case, the system reliability is, of course, a function of the common component reliability p .

Suppose that the component reliabilities all have the same value p . Let \mathbf{X} denote the state vector and Y denote the number of working components.

1. Give the probability density function of \mathbf{X} .
2. Give the probability density function of Y and identify the distribution by name and parameter.
3. Find the reliability of the k out of n system.

Answer

1. $f(x_1, x_2, \dots, x_n) = p^y(1-p)^{n-y}$ for $(x_1, x_2, \dots, x_n) \in \{0, 1\}^n$ where $y = x_1 + x_2 + \dots + x_n$
2. $g(k) = \binom{n}{y} p^y (1-p)^{n-y}$ for $y \in \{0, 1, \dots, n\}$ This is the binomial distribution with trial parameter n and success parameter p .
3. $r(p) = \sum_{i=k}^n \binom{n}{i} p^i (1-p)^{n-i}$

Suppose that we have 4 independent components, with common reliability $p = 0.8$. Let Y denote the number of working components.

1. Find the probability density function of Y explicitly.
2. Find the reliability of the parallel system.
3. Find the reliability of the 2 out of 4 system.
4. Find the reliability of the 3 out of 4 system.
5. Find the reliability of the series system.

Answer

1. $g(0) = 0.0016, g(1) = 0.0256, g(2) = 0.1536, g(3) = g(4) = 0.4096$
2. $r_{4,1} = 0.9984$
3. $r_{4,2} = 0.9729$
4. $r_{4,3} = 0.8192$
5. $r_{4,4} = 0.4096$

Suppose that we have 4 independent components, with reliabilities $p_1 = 0.6, p_2 = 0.7, p_3 = 0.8$, and $p_4 = 0.9$. Let Y denote the number of working components.

1. Find the probability density function of Y .
2. Find the reliability of the parallel system.
3. Find the reliability of the 2 out of 4 system.
4. Find the reliability of the 3 out of 4 system.
5. Find the reliability of the series system.

Answer

1. $g(0) = 0.0024, g(1) = 0.0404, g(2) = 0.2144, g(3) = 0.4404, g(4) = 0.3024$
2. $r_{4,1} = 0.9976$
3. $r_{4,2} = 0.9572$

4. $r_{4,3} = 0.7428$
5. $r_{4,4} = 0.3024$

The Poisson Distribution

Suppose that $a > 0$. Define f by

$$f(n) = e^{-a} \frac{a^n}{n!}, \quad n \in \mathbb{N} \quad (3.1.24)$$

1. f is a probability density function.
2. $f(n-1) < f(n)$ if and only if $n < a$.
3. If a is not a positive integer, there is a single mode at $\lfloor a \rfloor$.
4. If a is a positive integer, there are two modes at $a-1$ and a .

Proof

1. Recall from calculus, the exponential series

$$\sum_{n=0}^{\infty} \frac{a^n}{n!} = e^a \quad (3.1.25)$$

Hence f is a probability density function.

2. Note that $f(n-1) < f(n)$ if and only if $\frac{a^{n-1}}{(n-1)!} < \frac{a^n}{n!}$ if and only if $1 < \frac{a}{n}$.
3. By the same argument, $f(n-1) = f(n)$ if and only if $a = n$. If a is not a positive integer this cannot happen. Hence, letting $k = \lfloor a \rfloor$, it follows from (b) that $f(n) < f(k)$ if $n < k$ or $n > k$.
4. If a is a positive integer, then $f(a-1) = f(a)$. From (b), $f(n) < f(a-1)$ if $n < a-1$ and $f(n) < f(a)$ if $n > a$.

The distribution defined by the probability density function in the previous exercise is the *Poisson distribution* with parameter a , named after Simeon Poisson. Note that like the other named distributions we studied above ([hypergeometric](#) and [binomial](#)), the Poisson distribution is unimodal: the probability density function at first increases and then decreases, with either a single mode or two adjacent modes. The Poisson distribution is studied in detail in the Chapter on Poisson Processes, and is used to model the number of “random points” in a region of time or space, under certain ideal conditions. The parameter a is proportional to the size of the region of time or space.

Suppose that the customers arrive at a service station according to the Poisson model, at an average rate of 4 per hour. Thus, the number of customers N who arrive in a 2-hour period has the Poisson distribution with parameter 8.

1. Find the modes.
2. Find $\mathbb{P}(N \geq 6)$.

Answer

1. modes: 7, 8
2. $\mathbb{P}(N > 6) = 0.8088$

In the Poisson experiment, set $r = 4$ and $t = 2$. Run the simulation 1000 times and compare the empirical density function to the probability density function.

Suppose that the number of flaws N in a piece of fabric of a certain size has the Poisson distribution with parameter 2.5.

1. Find the mode.
2. Find $\mathbb{P}(N > 4)$.

Answer

1. mode: 2
2. $\mathbb{P}(N > 4) = 0.1088$

Suppose that the number of raisins N in a piece of cake has the Poisson distribution with parameter 10.

1. Find the modes.
2. Find $\mathbb{P}(8 \leq N \leq 12)$.

Answer

1. modes: 9, 10
2. $\mathbb{P}(8 \leq N \leq 12) = 0.5713$

A Zeta Distribution

Let g be the function defined by $g(n) = \frac{1}{n^2}$ for $n \in \mathbb{N}_+$.

1. Find the probability density function f that is **proportional** to g .
2. Find the mode of the distribution.
3. Find $\mathbb{P}(N \leq 5)$ where N has probability density function f .

Answer

1. $f(n) = \frac{6}{\pi^2 n^2}$ for $n \in \mathbb{N}_+$. Recall that $\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}$
2. Mode $n = 1$
3. $\mathbb{P}(N \leq 5) = \frac{5269}{600\pi^2}$

The distribution defined in the previous exercise is a member of the *zeta* family of distributions. Zeta distributions are used to model sizes or ranks of certain types of objects, and are studied in more detail in the chapter on Special Distributions.

Benford's Law

Let f be the function defined by $f(d) = \log(d+1) - \log(d) = \log\left(1 + \frac{1}{d}\right)$ for $d \in \{1, 2, \dots, 9\}$. (The logarithm function is the base 10 *common logarithm*, not the base e *natural logarithm*.)

1. Show that f is a probability density function.
2. Compute the values of f explicitly, and sketch the graph.
3. Find $\mathbb{P}(X \leq 3)$ where X has probability density function f .

Answer

1. Note that $\sum_{d=1}^9 f(d) = \log(10) = 1$. The sum collapses.

2.	d	1	2	3	4	5	6	7	8	9
	$f(d)$	0.3010	0.1761	0.1249	0.0969	0.0792	0.0669	0.0580	0.0512	0.0458

3. $\log(4) \approx 0.6020$

The distribution defined in the previous exercise is known as *Benford's law*, and is named for the American physicist and engineer Frank Benford. This distribution governs the leading digit in many real sets of data. Benford's law is studied in more detail in the chapter on Special Distributions.

Data Analysis Exercises

In the M&M data, let R denote the number of red candies and N the total number of candies. Compute and graph the empirical probability density function of each of the following:

1. R
2. N
3. R given $N > 57$

Answer

We denote the PDF of R by f and the PDF of N by g

1.	r	3	4	5	6	8	9	10	11	12	14	15	20
----	-----	---	---	---	---	---	---	----	----	----	----	----	----

$f(r)$	$\frac{1}{30}$	$\frac{3}{30}$	$\frac{3}{30}$	$\frac{2}{30}$	$\frac{4}{30}$	$\frac{5}{30}$	$\frac{2}{30}$	$\frac{1}{30}$	$\frac{3}{30}$	$\frac{3}{30}$	$\frac{3}{30}$	$\frac{1}{30}$
--------	----------------	----------------	----------------	----------------	----------------	----------------	----------------	----------------	----------------	----------------	----------------	----------------

2. n	50	53	54	55	56	57	58	59	60	61
$g(n)$	$\frac{1}{30}$	$\frac{1}{30}$	$\frac{1}{30}$	$\frac{4}{30}$	$\frac{4}{30}$	$\frac{3}{30}$	$\frac{9}{30}$	$\frac{3}{30}$	$\frac{2}{30}$	$\frac{2}{30}$

3. r	3	4	6	8	9	11	12	14	15
$f(r \mid N > 57)$	$\frac{1}{16}$	$\frac{1}{16}$	$\frac{1}{16}$	$\frac{3}{16}$	$\frac{3}{16}$	$\frac{1}{16}$	$\frac{1}{16}$	$\frac{3}{16}$	$\frac{2}{16}$

In the Cicada data, let G denotes gender, S species type, and W body weight (in grams). Compute the empirical probability density function of each of the following:

1. G
2. S
3. (G, S)
4. G given $W > 0.20$ grams.

Answer

We denote the PDF of G by g , the PDF of S by h and the PDF of (G, S) by f .

1. $g(0) = \frac{59}{104}, g(1) = \frac{45}{104}$
2. $h(0) = \frac{44}{104}, h(1) = \frac{6}{104}, h(2) = \frac{54}{104}$
3. $f(0, 0) = \frac{16}{104}, f(0, 1) = \frac{3}{104}, f(0, 2) = \frac{40}{104}, f(1, 0) = \frac{28}{104}, f(1, 1) = \frac{3}{104}, f(1, 2) = \frac{14}{104}$
4. $g(0 \mid W > 0.2) = \frac{31}{73}, g(1 \mid W > 0.2) = \frac{42}{73}$

This page titled [3.1: Discrete Distributions](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

3.2: Continuous Distributions

In the previous section, we considered discrete distributions. In this section, we study a complementary type of distribution. As usual, if you are a new student of probability, you may want to skip the technical details.

Basic Theory

Definitions and Basic Properties

As usual, our starting point is a random experiment modeled by a probability space $(S, \mathcal{S}, \mathbb{P})$. So to review, S is the set of outcomes, \mathcal{S} the collection of events, and \mathbb{P} the probability measure on the sample space (S, \mathcal{S}) . We use the terms *probability measure* and *probability distribution* synonymously in this text. Also, since we use a general definition of random variable, every probability measure can be thought of as the probability distribution of a random variable, so we can always take this point of view if we like. Indeed, most probability measures naturally have random variables associated with them.

In this section, we assume that $S \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$.

Details

Technically, S is a measurable subset of \mathbb{R}^n and \mathcal{S} is the σ -algebra measurable subsets of S . Typically in applications, S is defined by a finite number of inequalities involving elementary function.

Here is our first fundamental definition.

The probability measure \mathbb{P} is *continuous* if $\mathbb{P}(\{x\}) = 0$ for all $x \in S$.

The fact that each point is assigned probability 0 might seem impossible or paradoxical at first, but soon we will see very familiar analogies.

If \mathbb{P} is a continuous distribution then $\mathbb{P}(C) = 0$ for every countable $C \subseteq S$.

Proof

Since C is countable, it follows from the additivity axiom of probability that

$$\mathbb{P}(C) = \sum_{x \in C} \mathbb{P}(\{x\}) = 0 \quad (3.2.1)$$

Thus, continuous distributions are in complete contrast with discrete distributions, for which all of the probability mass is concentrated on the points in a discrete set. For a continuous distribution, the probability mass is *continuously* spread over S in some sense. In the picture below, the light blue shading is intended to suggest a continuous distribution of probability.

Figure 3.2.1: A continuous probability distribution on S

Typically, S is a region of \mathbb{R}^n defined by inequalities involving elementary functions, for example an interval in \mathbb{R} , a circular region in \mathbb{R}^2 , and a conical region in \mathbb{R}^3 . Suppose that \mathbb{P} is a continuous probability measure on S . The fact that each point in S has probability 0 is conceptually the same as the fact that an interval of \mathbb{R} can have positive length even though it is composed of points each of which has 0 length. Similarly, a region of \mathbb{R}^2 can have positive area even though it is composed of points (or curves) each of which has area 0. In the one-dimensional case, continuous distributions are used to model random variables that take values in intervals of \mathbb{R} , variables that can, in principle, be measured with any degree of accuracy. Such variables abound in applications and include

- length, area, volume, and distance

- time
- mass and weight
- charge, voltage, and current
- resistance, capacitance, and inductance
- velocity and acceleration
- energy, force, and work

Usually a continuous distribution can usually be described by certain type of function.

Suppose again that \mathbb{P} is a continuous distribution on S . A function $f : S \rightarrow [0, \infty)$ is a *probability density function* for \mathbb{P} if

$$\mathbb{P}(A) = \int_A f(x) dx, \quad A \in \mathcal{S} \quad (3.2.2)$$

Details

Technically, f must be measurable and is a probability density function of \mathbb{P} *with respect* to Lebesgue measure, the standard measure on \mathbb{R}^n . Moreover, the integral is the Lebesgue integral, but the ordinary Riemann integral of calculus suffices for the sets that occur in typical applications.

So the probability distribution \mathbb{P} is completely determined by the probability density function f . As a special case, note that $\int_S f(x) dx = \mathbb{P}(S) = 1$. Conversely, a nonnegative function on S with this property defines a probability measure.

A function $f : S \rightarrow [0, \infty)$ that satisfies $\int_S f(x) dx = 1$ is a *probability density function* on S and then \mathbb{P} defined as follows is a continuous probability measure on S :

$$\mathbb{P}(A) = \int_A f(x) dx, \quad A \in \mathcal{S} \quad (3.2.3)$$

Proof

Figure 3.2.2: A continuous distribution is completely determined by its probability density function

Note that we can always extend f to a probability density function on a subset of \mathbb{R}^n that contains S , or to all of \mathbb{R}^n , by defining $f(x) = 0$ for $x \notin S$. This extension sometimes simplifies notation. Put another way, we can be a bit sloppy about the “set of values” of the random variable. So for example if $a, b \in \mathbb{R}$ with $a < b$ and X has a continuous distribution on the interval $[a, b]$, then we could also say that X has a continuous distribution on (a, b) or $[a, b)$, or $(a, b]$.

The points $x \in S$ that maximize the probability density function f are important, just as in the discrete case.

Suppose that \mathbb{P} is a continuous distribution on S with probability density function f . An element $x \in S$ that maximizes f is a *mode* of the distribution.

If there is only one mode, it is sometimes used as a measure of the *center* of the distribution.

You have probably noticed that probability density functions for continuous distributions are analogous to probability density functions for discrete distributions, with integrals replacing sums. However, there are essential differences. First, every discrete distribution has a unique probability density function f given by $f(x) = \mathbb{P}(\{x\})$ for $x \in S$. For a continuous distribution, the existence of a probability density function is not guaranteed. The advanced section on absolute continuity and density functions has several examples of continuous distribution that do not have density functions, and gives conditions that are necessary and sufficient for the existence of a probability density function. Even if a probability density function f exists, it is *never* unique. Note that the values of f on a finite (or even countably infinite) set of points could be changed to other nonnegative values and the new function would still be a probability density function for the same distribution. The critical fact is that only *integrals* of f are important. Second, the values of the PDF f for a discrete distribution are probabilities, and in particular $f(x) \leq 1$ for $x \in S$. For a

continuous distribution the values are not probabilities and in fact it's possible that $f(x) > 1$ for some or even all $x \in S$. Further, f can be unbounded on S . In the typical calculus interpretation, $f(x)$ really is probability *density* at x . That is, $f(x) dx$ is approximately the probability of a "small" region of size dx about x .

Constructing Probability Density Functions

Just as in the discrete case, a nonnegative function on S can often be scaled to produce a probability density function.

Suppose that $g: S \rightarrow [0, \infty)$ and let

$$c = \int_S g(x) dx \quad (3.2.4)$$

If $0 < c < \infty$ then f defined by $f(x) = \frac{1}{c}g(x)$ for $x \in S$ defines a probability density function for a continuous distribution on S .

Proof

Technically, the function g is measurable. Technicalities aside, the proof is trivial. Clearly $f(x) \geq 0$ for $x \in S$ and

$$\int_S f(x) dx = \frac{1}{c} \int_S g(x) dx = \frac{c}{c} = 1 \quad (3.2.5)$$

Note again that f is just a scaled version of g . So this result can be used to construct probability density functions with desired properties (domain, shape, symmetry, and so on). The constant c is sometimes called the *normalizing constant* of g .

Conditional Densities

Suppose now that X is a random variable defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and that X has a continuous distribution on S . A probability density function for X is based on the underlying probability measure on the sample space (Ω, \mathcal{F}) . This measure could be a conditional probability measure, conditioned on a given event $E \in \mathcal{F}$ with $\mathbb{P}(E) > 0$. Assuming that the conditional probability density function exists, the usual notation is

$$f(x | E), \quad x \in S \quad (3.2.6)$$

Note, however, that except for notation, no new concepts are involved. The defining property is

$$\int_A f(x | E) dx = \mathbb{P}(X \in A | E), \quad A \in \mathcal{S} \quad (3.2.7)$$

and all results that hold for probability density functions in general hold for conditional probability density functions. The event E could be an event described in terms of the random variable X itself:

Suppose that X has a continuous distribution on S with probability density function f and that $B \in \mathcal{S}$ with $\mathbb{P}(X \in B) > 0$. The conditional probability density function of X given $X \in B$ is the function on B given by

$$f(x | X \in B) = \frac{f(x)}{\mathbb{P}(X \in B)}, \quad x \in B \quad (3.2.8)$$

Proof

For $A \in \mathcal{S}$ with $A \subseteq B$,

$$\int_A \frac{f(x)}{\mathbb{P}(X \in B)} dx = \frac{1}{\mathbb{P}(X \in B)} \int_A f(x) dx = \frac{\mathbb{P}(X \in A)}{\mathbb{P}(X \in B)} = \mathbb{P}(X \in A | X \in B) \quad (3.2.9)$$

Of course, $\mathbb{P}(X \in B) = \int_B f(x) dx$ and hence is the normalizing constant for the restriction of f to B , as in (8)

Examples and Applications

As always, try the problems yourself before looking at the answers.

The Exponential Distribution

Let f be the function defined by $f(t) = re^{-rt}$ for $t \in [0, \infty)$, where $r \in (0, \infty)$ is a parameter.

1. Show that f is a probability density function.
2. Draw a careful sketch of the graph of f , and state the important qualitative features.

Proof

1. Note that $f(t) > 0$ for $t \geq 0$. Also $\int_0^\infty e^{-rt} dt = \frac{1}{r}$ so f is a PDF.
2. f is decreasing and concave upward so the mode is 0. $f(x) \rightarrow 0$ as $x \rightarrow \infty$.

The distribution defined by the probability density function in the previous exercise is called the *exponential distribution* with rate parameter r . This distribution is frequently used to model random times, under certain assumptions. Specifically, in the Poisson model of random points in time, the times between successive arrivals have independent exponential distributions, and the parameter r is the average rate of arrivals. The exponential distribution is studied in detail in the chapter on Poisson Processes.

The lifetime T of a certain device (in 1000 hour units) has the exponential distribution with parameter $r = \frac{1}{2}$. Find

1. $\mathbb{P}(T > 2)$
2. $\mathbb{P}(T > 3 \mid T > 1)$

Answer

1. $e^{-1} \approx 0.3679$
2. $e^{-1} \approx 0.3679$

In the gamma experiment, set $n = 1$ to get the exponential distribution. Vary the rate parameter r and note the shape of the probability density function. For various values of r , run the simulation 1000 times and compare the empirical density function with the probability density function.

A Random Angle

In *Bertrand's problem*, a certain random angle Θ has probability density function f given by $f(\theta) = \sin \theta$ for $\theta \in [0, \frac{\pi}{2}]$.

1. Show that f is a probability density function.
2. Draw a careful sketch of the graph f , and state the important qualitative features.
3. Find $\mathbb{P}(\Theta < \frac{\pi}{4})$.

Answer

1. Note that $\sin \theta \geq 0$ for $0 \leq \theta \leq \frac{\pi}{2}$ and $\int_0^{\pi/2} \sin \theta d\theta = 1$.
2. f is increasing and concave downward so the mode is $\frac{\pi}{2}$.
3. $1 - \frac{1}{\sqrt{2}} \approx 0.2929$

Bertrand's problem is named for Joseph Louis Bertrand and is studied in more detail in the chapter on Geometric Models.

In Bertrand's experiment, select the model with uniform distance. Run the simulation 1000 times and compute the empirical probability of the event $\{\Theta < \frac{\pi}{4}\}$. Compare with the true probability in the previous exercise.

Gamma Distributions

Let g_n be the function defined by $g_n(t) = e^{-t} \frac{t^n}{n!}$ for $t \in [0, \infty)$ where $n \in \mathbb{N}$ is a parameter.

1. Show that g_n is a probability density function for each $n \in \mathbb{N}$.
2. Draw a careful sketch of the graph of g_n , and state the important qualitative features.

Proof

1. Note that $g_n(t) \geq 0$ for $t \geq 0$. Also, g_0 is the probability density function of the exponential distribution with parameter 1. For $n \in \mathbb{N}_+$, integration by parts with $u = t^n/n!$ and $dv = e^{-t} dt$ gives $\int_0^\infty g_n(t) dt = \int_0^\infty g_{n-1}(t) dt$. Hence it follows by induction that g_n is a PDF for each $n \in \mathbb{N}_+$.

2. g_0 is decreasing and concave downward, with mode $t = 0$. For $n > 0$, g_n increases and then decreases, with mode $t = n$. g_1 is concave downward and then upward, with inflection point at $t = 2$. For $n > 1$, g_n is concave upward, then downward, then upward again, with inflection points at $n \pm \sqrt{n}$. For all $n \in \mathbb{N}$, $g_n(t) \rightarrow 0$ as $t \rightarrow \infty$.

Interestingly, we showed in the last section on discrete distributions, that $f_t(n) = g_n(t)$ is a probability density function on \mathbb{N} for each $t \geq 0$ (it's the Poisson distribution with parameter t). The distribution defined by the probability density function g_n belongs to the family of *Erlang distributions*, named for Agner Erlang; $n + 1$ is known as the *shape parameter*. The Erlang distribution is studied in more detail in the chapter on the Poisson Process. In turn the Erlang distribution belongs to the more general family of *gamma distributions*. The gamma distribution is studied in more detail in the chapter on Special Distributions.

In the gamma experiment, keep the default rate parameter $r = 1$. Vary the shape parameter and note the shape and location of the probability density function. For various values of the shape parameter, run the simulation 1000 times and compare the empirical density function with the probability density function.

Suppose that the lifetime of a device T (in 1000 hour units) has the gamma distribution [above](#) with $n = 2$. Find each of the following:

1. $\mathbb{P}(T > 3)$.
2. $\mathbb{P}(T \leq 2)$
3. $\mathbb{P}(1 \leq T \leq 4)$

Answer

1. $\frac{17}{2}e^{-3} \approx 0.4232$
2. $1 - 5e^{-2} \approx 0.3233$
3. $\frac{5}{2}e^{-1} - 13e^{-4} \approx 0.6816$

Beta Distributions

Let f be the function defined by $f(x) = 6x(1 - x)$ for $x \in [0, 1]$.

1. Show that f is a probability density function.
2. Draw a careful sketch of the graph of f , and state the important qualitative features.

Answer

1. Note that $f(x) \geq 0$ for $x \in [0, 1]$. Also, $\int_0^1 x(1 - x) dx = \frac{1}{6}$, so f is a PDF
2. f increases and then decreases, with mode at $x = \frac{1}{2}$. f is concave downward. f is symmetric about $x = \frac{1}{2}$ (in fact, the graph is a parabola).

Let f be the function defined by $f(x) = 12x^2(1 - x)$ for $x \in [0, 1]$.

1. Show that f is a probability density function.
2. Draw a careful sketch the graph of f , and state the important qualitative features.

Answer

1. Note that $f(x) \geq 0$ for $0 \leq x \leq 1$. Also $\int_0^1 x^2(1 - x) dx = \frac{1}{12}$, so f is a PDF.
2. f increases and then decreases, with mode at $x = \frac{2}{3}$. f is concave upward and then downward, with inflection point at $x = \frac{1}{3}$.

The distributions defined in the last two exercises are examples of *beta distributions*. These distributions are widely used to model random proportions and probabilities, and physical quantities that take values in bounded intervals (which, after a change of units, can be taken to be $[0, 1]$). Beta distributions are studied in detail in the chapter on Special Distributions.

In the special distribution simulator, select the beta distribution. For the following parameter values, note the shape of the probability density function. Run the simulation 1000 times and compare the empirical density function with the probability density function.

1. $a = 2, b = 2$. This gives the first beta distribution [above](#).
2. $a = 3, b = 2$. This gives the second beta distribution [above](#).

Suppose that P is a random proportion. Find $\mathbb{P}\left(\frac{1}{4} \leq P \leq \frac{3}{4}\right)$ in each of the following cases:

1. P has the first beta distribution [above](#).
2. P has the second beta distribution [above](#).

Answer

1. $\frac{11}{16}$
2. $\frac{11}{16}$

Let f be the function defined by

$$f(x) = \frac{1}{\pi \sqrt{x(1-x)}}, \quad x \in (0, 1) \quad (3.2.10)$$

1. Show that f is a probability density function.
2. Draw a careful sketch of the graph of f , and state the important qualitative features.

Answer

1. Note that $f(x) > 0$ for $0 < x < 1$. Using the substitution $u = \sqrt{x}$ gives

$$\int_0^1 \frac{1}{\sqrt{x(1-x)}} dx = \int_0^1 \frac{2}{\sqrt{1-u^2}} du = 2 \arcsin u \Big|_0^1 = \pi \quad (3.2.11)$$

Thus f is a PDF.

2. f is symmetric about $x = \frac{1}{2}$. f decreases and then increases, with minimum at $x = \frac{1}{2}$. $f(x) \rightarrow \infty$ as $x \downarrow 0$ and as $x \uparrow 1$ so the distribution has no mode. f is concave upward.

The distribution defined in the last exercise is also a member of the beta family of distributions. But it is also known as the (standard) *arcsine distribution*, because of the arcsine function that arises in the proof that f is a probability density function. The arcsine distribution has applications to a very important random process known as Brownian motion, named for the Scottish botanist Robert Brown. Arcsine distributions are studied in more generality in the chapter on Special Distributions.

In the special distribution simulator, select the (continuous) arcsine distribution and keep the default parameter values. Run the simulation 1000 times and compare the empirical density function with the probability density function.

Suppose that X_t represents the change in the price of a stock at time t , relative to the value at an initial reference time 0. We treat t as a continuous variable measured in weeks. Let $T = \max\{t \in [0, 1] : X_t = 0\}$, the last time during the first week that the stock price was unchanged over its initial value. Under certain ideal conditions, T will have the arcsine distribution. Find each of the following:

1. $\mathbb{P}\left(T < \frac{1}{4}\right)$
2. $\mathbb{P}\left(T \geq \frac{1}{2}\right)$
3. $\mathbb{P}\left(T \leq \frac{3}{4}\right)$

Answer

1. $\frac{1}{3}$
2. $\frac{1}{2}$
3. $\frac{2}{3}$

Open the Brownian motion experiment and select the *last zero* variable. Run the experiment in single step mode a few times. The random process that you observe models the price of the stock in the previous exercise. Now run the experiment 1000 times and compute the empirical probability of each event in the previous exercise.

The Pareto Distribution

Let g be the function defined by $g(x) = 1/x^b$ for $x \in [1, \infty)$, where $b \in (0, \infty)$ is a parameter.

1. Draw a careful sketch the graph of g , and state the important qualitative features.
2. Find the values of b for which there exists a probability density function f (8)proportional to g . Identify the mode.

Answer

1. g is decreasing and concave upward, with $g(x) \rightarrow 0$ as $x \rightarrow \infty$.
2. Note that if $b \neq 1$

$$\int_1^\infty x^{-b} dx = \frac{x^{1-b}}{1-b} \Big|_1^\infty = \begin{cases} \infty, & 0 < b < 1 \\ \frac{1}{b-1}, & 1 < b < \infty \end{cases} \quad (3.2.12)$$

When $b = 1$ we have $\int_1^\infty x^{-1} dx = \ln x \Big|_1^\infty = \infty$. Thus, when $0 < b \leq 1$, there is no PDF proportional to g . When $b > 1$, the PDF proportional to g is $f(x) = \frac{b-1}{x^b}$ for $x \in [1, \infty)$. The mode is 1.

Note that the qualitative features of g are the same, regardless of the value of the parameter $b > 0$, but only when $b > 1$ can g be normalized into a probability density function. In this case, the distribution is known as the *Pareto distribution*, named for Vilfredo Pareto. The parameter $a = b - 1$, so that $a > 0$, is known as the *shape parameter*. Thus, the Pareto distribution with shape parameter a has probability density function

$$f(x) = \frac{a}{x^{a+1}}, \quad x \in [1, \infty) \quad (3.2.13)$$

The Pareto distribution is widely used to model certain economic variables and is studied in detail in the chapter on Special Distributions.

In the special distribution simulator, select the Pareto distribution. Leave the scale parameter fixed, but vary the shape parameter, and note the shape of the probability density function. For various values of the shape parameter, run the simulation 1000 times and compare the empirical density function with the probability density function.

Suppose that the income X (in appropriate units) of a person randomly selected from a population has the Pareto distribution with shape parameter $a = 2$. Find each of the following:

1. $\mathbb{P}(X > 2)$
2. $\mathbb{P}(X \leq 4)$
3. $\mathbb{P}(3 \leq X \leq 5)$

Answer

1. $\frac{1}{4}$
2. $\frac{15}{16}$
3. $\frac{16}{225}$

The Cauchy Distribution

Let f be the function defined by

$$f(x) = \frac{1}{\pi(x^2 + 1)}, \quad x \in \mathbb{R} \quad (3.2.14)$$

1. Show that f is a probability density function.
2. Draw a careful sketch the graph of f , and state the important qualitative features.

Answer

1. Note that $f(x) > 0$ for $x \in \mathbb{R}$. Also

$$\int_{-\infty}^\infty \frac{1}{1+x^2} dx = \arctan x \Big|_{-\infty}^\infty = \pi \quad (3.2.15)$$

and hence f is a PDF.

2. f increases and then decreases, with mode $x = 0$. f is concave upward, then downward, then upward again, with inflection points at $x = \pm \frac{1}{\sqrt{3}}$. f is symmetric about $x = 0$.

The distribution constructed in the previous exercise is known as the (standard) *Cauchy distribution*, named after Augustin Cauchy. It might also be called the *arctangent distribution*, because of the appearance of the arctangent function in the proof that f is a probability density function. In this regard, note the similarity to the arcsine distribution [above](#). The Cauchy distribution is studied in more generality in the chapter on Special Distributions. Note also that the Cauchy distribution is obtained by normalizing the function $x \mapsto \frac{1}{1+x^2}$; the graph of this function is known as the *witch of Agnesi*, in honor of Maria Agnesi.

In the special distribution simulator, select the Cauchy distribution with the default parameter values. Run the simulation 1000 times and compare the empirical density function with the probability density function.

A light source is 1 meter away from position 0 on an infinite, straight wall. The angle Θ that the light beam makes with the perpendicular to the wall is randomly chosen from the interval $(-\frac{\pi}{2}, \frac{\pi}{2})$. The position $X = \tan(\Theta)$ of the light beam on the wall has the standard Cauchy distribution. Find each of the following:

1. $\mathbb{P}(-1 < X < 1)$.
2. $\mathbb{P}\left(X \geq \frac{1}{\sqrt{3}}\right)$
3. $\mathbb{P}(X \leq \sqrt{3})$

Answer

1. $\frac{1}{2}$
2. $\frac{1}{3}$
3. $\frac{2}{3}$

The Cauchy experiment (with the default parameter values) is a simulation of the experiment in the last exercise.

1. Run the experiment a few times in single step mode.
2. Run the experiment 1000 times and compare the empirical density function with the probability density function.
3. Using the data from (b), compute the relative frequency of each event in the previous exercise, and compare with the true probability.

The Standard Normal Distribution

Let ϕ be the function defined by $\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}$ for $z \in \mathbb{R}$.

1. Show that ϕ is a probability density function.
2. Draw a careful sketch the graph of ϕ , and state the important qualitative features.

Proof

2. Note that $\phi(z) > 0$ for $z \in \mathbb{R}$. Let $c = \int_{-\infty}^{\infty} e^{-z^2/2} dz$. Then

$$c^2 = \int_{-\infty}^{\infty} e^{-x^2/2} dx \int_{-\infty}^{\infty} e^{-y^2/2} dy = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-(x^2+y^2)/2} dx dy \quad (3.2.16)$$

Change to polar coordinates: $x = r \cos \theta$, $y = r \sin \theta$ where $r \in [0, \infty)$ and $\theta \in [0, 2\pi)$. Then $x^2 + y^2 = r^2$ and $dx dy = r dr d\theta$. Hence

$$c^2 = \int_0^{2\pi} \int_0^{\infty} r e^{-r^2/2} dr d\theta \quad (3.2.17)$$

Using the simple substitution $u = r^2$, the inner integral is $\int_0^{\infty} e^{-u/2} du = 1$. Then the outer integral is $\int_0^{2\pi} 1 d\theta = 2\pi$. Hence $c = \sqrt{2\pi}$ and so ϕ is a PDF.

3. Note that ϕ is symmetric about 0. ϕ increases and then decreases, with mode $z = 0$. ϕ is concave upward, then downward, then upward again, with inflection points at $z = \pm 1$. $\phi(z) \rightarrow 0$ as $z \rightarrow \infty$ and as $z \rightarrow -\infty$.

The distribution defined in the last exercise is the *standard normal distribution*, perhaps the most important distribution in probability and statistics. Its importance stems largely from the central limit theorem, one of the fundamental theorems in probability. In particular, normal distributions are widely used to model physical measurements that are subject to small, random errors. The family of normal distributions is studied in more generality in the chapter on Special Distributions.

In the special distribution simulator, select the normal distribution and keep the default parameter values. Run the simulation 1000 times and compare the empirical density function and the probability density function.

The function $z \mapsto e^{-z^2/2}$ is a notorious example of an integrable function that does not have an antiderivative that can be expressed in closed form in terms of other elementary functions. (That's why we had to resort to the polar coordinate trick to show that ϕ is a probability density function.) So probabilities involving the normal distribution are usually computed using mathematical or statistical software.

Suppose that the error Z in the length of a certain machined part (in millimeters) has the standard normal distribution. Use mathematical software to approximate each of the following:

1. $\mathbb{P}(-1 \leq Z \leq 1)$
2. $\mathbb{P}(Z > 2)$
3. $\mathbb{P}(Z < -3)$

Answer

1. 0.6827
2. 0.0228
3. 0.0013

The Extreme Value Distribution

Let f be the function defined by $f(x) = e^{-x}e^{-e^{-x}}$ for $x \in \mathbb{R}$.

1. Show that f is a probability density function.
2. Draw a careful sketch of the graph of f , and state the important qualitative features.
3. Find $\mathbb{P}(X > 0)$, where X has probability density function f .

Answer

1. Note that $f(x) > 0$ for $x \in \mathbb{R}$. Using the substitution $u = e^{-x}$,

$$\int_{-\infty}^{\infty} e^{-x} e^{-e^{-x}} dx = \int_0^{\infty} e^{-u} du = 1 \quad (3.2.18)$$

(note that the integrand in the last integral is the exponential PDF with parameter 1.

2. f increases and then decreases, with mode $x = 0$. f is concave upward, then downward, then upward again, with inflection points at $x = \pm \ln[(3 + \sqrt{5})/2]$. Note however that f is not symmetric about 0. $f(x) \rightarrow 0$ as $x \rightarrow \infty$ and as $x \rightarrow -\infty$.
3. $1 - e^{-1} \approx 0.6321$

The distribution in the last exercise is the (standard) *type 1 extreme value distribution*, also known as the *Gumbel distribution* in honor of Emil Gumbel. Extreme value distributions are studied in more generality in the chapter on Special Distributions.

In the special distribution simulator, select the extreme value distribution. Keep the default parameter values and note the shape and location of the probability density function. Run the simulation 1000 times and compare the empirical density function with the probability density function.

The Logistic Distribution

Let f be the function defined by

$$f(x) = \frac{e^x}{(1 + e^x)^2}, \quad x \in \mathbb{R} \quad (3.2.19)$$

1. Show that f is a probability density function.
2. Draw a careful sketch the graph of f , and state the important qualitative features.
3. Find $\mathbb{P}(X > 1)$, where X has probability density function f .

Answer

1. Note that $f(x) > 0$ for $x \in \mathbb{R}$. The substitution $u = e^x$ gives

$$\int_{-\infty}^{\infty} f(x) dx = \int_0^{\infty} \frac{1}{(1+u)^2} du = 1 \quad (3.2.20)$$

2. f is symmetric about 0. f increases and then decreases with mode $x = 0$. f is concave upward, then downward, then upward again, with inflection points at $x = \pm \ln(2 + \sqrt{3})$. $f(x) \rightarrow 0$ as $x \rightarrow \infty$ and as $x \rightarrow -\infty$.
3. $\frac{1}{1+e} \approx 0.2689$

The distribution in the last exercise is the (standard) *logistic distribution*. Logistic distributions are studied in more generality in the chapter on Special Distributions.

In the special distribution simulator, select the logistic distribution. Keep the default parameter values and note the shape and location of the probability density function. Run the simulation 1000 times and compare the empirical density function with the probability density function.

Weibull Distributions

Let f be the function defined by $f(t) = 2te^{-t^2}$ for $t \in [0, \infty)$.

1. Show that f is a probability density function.
2. Draw a careful sketch the graph of f , and state the important qualitative features.

Answer

1. Note that $f(t) \geq 0$ for $t \geq 0$. The substitution $u = t^2$ gives $\int_0^{\infty} f(t) dt = \int_0^{\infty} e^{-u} du = 1$.
2. f increases and then decreases, with mode $t = 1/\sqrt{2}$. f is concave downward and then upward, with inflection point at $t = \sqrt{3/2}$. $f(t) \rightarrow 0$ as $t \rightarrow \infty$.

Let f be the function defined by $f(t) = 3t^2e^{-t^3}$ for $t \geq 0$.

1. Show that f is a probability density function.
2. Draw a careful sketch the graph of f , and state the important qualitative features.

Answer

1. Note that $f(t) \geq 0$ for $t \geq 0$. The substitution $u = t^3$ gives

$$\int_0^{\infty} f(t) dt = \int_0^{\infty} e^{-u} du = 1 \quad (3.2.21)$$

2. f increases and then decreases, with mode $t = (\frac{2}{3})^{1/3}$. f is concave upward, then downward, then upward again, with inflection points at $t = (1 \pm \frac{1}{3}\sqrt{7})^{1/3}$. $f(t) \rightarrow 0$ as $t \rightarrow \infty$.

The distributions in the last two exercises are examples of *Weibull distributions*, name for Waloddi Weibull. Weibull distributions are studied in more generality in the chapter on Special Distributions. They are often used to model random failure times of devices (in appropriately scaled units).

In the special distribution simulator, select the Weibull distribution. For each of the following values of the shape parameter k , note the shape and location of the probability density function. Run the simulation 1000 times and compare the empirical density function with the probability density function.

1. $k = 2$. This gives the first Weibull distribution [above](#).
2. $k = 3$. This gives the second Weibull distribution [above](#).

Suppose that T is the failure time of a device (in 1000 hour units). Find $\mathbb{P}(T > \frac{1}{2})$ in each of the following cases:

1. T has the first Weibull distribution [above](#).
2. T has the second Weibull distribution [above](#).

Answer

1. $e^{-1/4} \approx 0.7788$
2. $e^{-1/8} \approx 0.8825$

Additional Examples

Let f be the function defined by $f(x) = -\ln x$ for $x \in (0, 1]$.

1. Show that f is a probability density function.
2. Draw a careful sketch of the graph of f , and state the important qualitative features.
3. Find $\mathbb{P}(\frac{1}{3} \leq X \leq \frac{1}{2})$ where X has the probability density function in (a).

Answer

1. Note that $-\ln x \geq 0$ for $0 < x \leq 1$. Integration by parts with $u = -\ln x$ and $dv = dx$ gives

$$\int_0^1 -\ln x \, dx = -x \ln x \Big|_0^1 + \int_0^1 1 \, dx = 1 \quad (3.2.22)$$

2. f is decreasing and concave upward, with $f(x) \rightarrow \infty$ as $x \downarrow 0$, so there is no mode.
3. $\frac{1}{2} \ln 2 - \frac{1}{3} \ln 3 + \frac{1}{6} \approx 0.147$

Let f be the function defined by $f(x) = 2e^{-x}(1 - e^{-x})$ for $x \in [0, \infty)$.

1. Show that f is a probability density function.
2. Draw a careful sketch of the graph of f , and give the important qualitative features.
3. Find $\mathbb{P}(X \geq 1)$ where X has the probability density function in (a).

Answer

1. Note that $f(x) > 0$ for $0 < x < \infty$. Also, $\int_0^\infty (e^{-x} - e^{-2x}) \, dx = \frac{1}{2}$, so f is a PDF.
2. f increases and then decreases, with mode $x = \ln(2)$. f is concave downward and then upward, with an inflection point at $x = \ln(4)$. $f(x) \rightarrow 0$ as $x \rightarrow \infty$.
3. $2e^{-1} - e^{-2} \approx 0.6004$

The following problems deal with two and three dimensional random vectors having continuous distributions. The idea of [normalizing](#) a function to form a probability density function is important for some of the problems. The relationship between the distribution of a vector and the distribution of its components will be discussed later, in the section on joint distributions.

Let f be the function defined by $f(x, y) = x + y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.

1. Show that f is a probability density function, and identify the mode.
2. Find $\mathbb{P}(Y \geq X)$ where (X, Y) has the probability density function in (a).
3. Find the conditional density of (X, Y) given $\{X < \frac{1}{2}, Y < \frac{1}{2}\}$.

Answer

1. mode $(1, 1)$
2. $\frac{1}{2}$
3. $f(x, y \mid X < \frac{1}{2}, Y < \frac{1}{2}) = 8(x + y)$ for $0 < x < \frac{1}{2}, 0 < y < \frac{1}{2}$

Let g be the function defined by $g(x, y) = x + y$ for $0 \leq x \leq y \leq 1$.

1. Find the probability density function f that is [proportional](#) to g .
2. Find $\mathbb{P}(Y \geq 2X)$ where (X, Y) has the probability density function in (a).

Answer

1. $f(x, y) = 2(x + y), 0 \leq x \leq y \leq 1$
2. $\frac{5}{12}$

Let g be the function defined by $g(x, y) = x^2y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.

1. Find the probability density function f that is **proportional** to g .
2. Find $\mathbb{P}(Y \geq X)$ where (X, Y) has the probability density function in (a).

Answer

1. $f(x, y) = 6x^2y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$
2. $\frac{2}{5}$

Let g be the function defined by $g(x, y) = x^2y$ for $0 \leq x \leq y \leq 1$.

1. Find the probability density function f that is **proportional** to g .
2. Find $P(Y \geq 2X)$ where (X, Y) has the probability density function in (a).

Answer

1. $f(x, y) = 15x^2y$ for $0 \leq x \leq y \leq 1$
2. $\frac{1}{8}$

Let g be the function defined by $g(x, y, z) = x + 2y + 3z$ for $0 \leq x \leq 1, 0 \leq y \leq 1, 0 \leq z \leq 1$.

1. Find the probability density function f that is **proportional** to g .
2. Find $\mathbb{P}(X \leq Y \leq Z)$ where (X, Y, Z) has the probability density function in (a).

Answer

1. $f(x, y, z) = \frac{1}{3}(x + 2y + 3z)$ for $0 \leq x \leq 1, 0 \leq y \leq 1, 0 \leq z \leq 1$
2. $\frac{7}{36}$

Let g be the function defined by $g(x, y) = e^{-x}e^{-y}$ for $0 \leq x \leq y < \infty$.

1. Find the probability density function f that is **proportional** to g .
2. Find $\mathbb{P}(X + Y < 1)$ where (X, Y) has the probability density function in (a).

Answer

1. $f(x, y) = 2e^{-x}e^{-y}, 0 < x < y < \infty$
2. $1 - 2e^{-1} \approx 0.2642$

Continuous Uniform Distributions

Our next discussion will focus on an important class of continuous distributions that are defined purely in terms of geometry. We need a preliminary definition.

For $n \in \mathbb{N}_+$, the standard measure λ_n on \mathbb{R}^n is given by

$$\lambda_n(A) = \int_A 1 \, dx, \quad A \subseteq \mathbb{R}^n \quad (3.2.23)$$

In particular, $\lambda_1(A)$ is the *length* of $A \subseteq \mathbb{R}$, $\lambda_2(A)$ is the *area* of $A \subseteq \mathbb{R}^2$, and $\lambda_3(A)$ is the *volume* of $A \subseteq \mathbb{R}^3$.

Details

Technically, λ_n is Lebesgue measure on the σ -algebra of measurable subsets of \mathbb{R}^n . The name is in honor of Henri Lebesgue. The representation above in terms of the standard Riemann integral of calculus works for the sets that occur in typical applications. For the remainder of this discussion, we assume that all subsets of \mathbb{R}^n that are mentioned are measurable

Note that if $n > 1$, the integral above is a multiple integral. Generally, $\lambda_n(A)$ is referred to as the *n-dimensional volume* of $A \subseteq \mathbb{R}^n$.

Suppose that $S \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$ with $0 < \lambda_n(S) < \infty$.

1. the function f defined by $f(x) = 1/\lambda_n(S)$ for $x \in S$ is a probability density function on S .
2. The probability measure associated with f is given by $\mathbb{P}(A) = \lambda_n(A)/\lambda_n(S)$ for $A \subseteq S$, and is known as the *uniform distribution* on S .

Proof

The proof is simple: Clearly $f(x) > 0$ for $x \in S$ and

$$\int_A f(x) dx = \frac{1}{\lambda_n(S)} \int_A 1 dx = \frac{\lambda_n(A)}{\lambda_n(S)}, \quad A \subseteq S \quad (3.2.24)$$

In particular, when $A = S$ we have $\int_S f(x) dx = 1$.

Note that the probability assigned to a set $A \subseteq \mathbb{R}^n$ is proportional to the size of A , as measured by λ_n . Note also that in both the discrete and continuous cases, the uniform distribution on a set S has constant probability density function on S . The uniform distribution on a set S governs a point X chosen “at random” from S , and in the continuous case, such distributions play a fundamental role in various Geometric Models. Uniform distributions are studied in more generality in the chapter on Special Distributions.

The most important special case is the uniform distribution on an interval $[a, b]$ where $a, b \in \mathbb{R}$ and $a < b$. In this case, the probability density function is

$$f(x) = \frac{1}{b-a}, \quad a \leq x \leq b \quad (3.2.25)$$

This distribution models a point chosen “at random” from the interval. In particular, the uniform distribution on $[0, 1]$ is known as the *standard uniform distribution*, and is very important because of its simplicity and the fact that it can be transformed into a variety of other probability distributions on \mathbb{R} . Almost all computer languages have procedures for simulating independent, standard uniform variables, which are called *random numbers* in this context.

Conditional distributions corresponding to a uniform distribution are also uniform.

Suppose that $R \subseteq S \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$, and that $\lambda_n(R) > 0$ and $\lambda_n(S) < \infty$. If \mathbb{P} is the uniform distribution on S , then the conditional distribution given R is uniform on R .

Proof

The proof is very simple: For $A \subseteq R$,

$$\mathbb{P}(A | R) = \frac{\mathbb{P}(A \cap R)}{\mathbb{P}(R)} = \frac{\mathbb{P}(A)}{\mathbb{P}(R)} = \frac{\lambda_n(A)/\lambda_n(S)}{\lambda_n(R)/\lambda_n(S)} = \frac{\lambda_n(A)}{\lambda_n(R)} \quad (3.2.26)$$

The last theorem has important implications for simulations. If we can simulate a random variable that is uniformly distributed on a set, we can simulate a random variable that is uniformly distributed on a subset.

Suppose again that $R \subseteq S \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$, and that $\lambda_n(R) > 0$ and $\lambda_n(S) < \infty$. Suppose further that $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of independent random variables, each uniformly distributed on S . Let $N = \min\{k \in \mathbb{N}_+ : X_k \in R\}$. Then

1. N has the geometric distribution on \mathbb{N}_+ with success parameter $p = \lambda_n(R)/\lambda_n(S)$.
2. X_N is uniformly distributed on R .

Proof

1. Since the variables are uniformly distributed on S , $\mathbb{P}(X_k \in R) = \lambda_n(R)/\lambda_n(S)$ for each $k \in \mathbb{N}_+$. Since the variables are independent, each point is in R or not independently. Hence N , the index of the first point to fall in R , has the geometric distribution on \mathbb{N}_+ with success probability $p = \lambda_n(R)/\lambda_n(S)$. That is, $\mathbb{P}(N = k) = (1-p)^{k-1}p$ for $k \in \mathbb{N}_+$.
2. Note that $p \in (0, 1]$, so $\mathbb{P}(N \in \mathbb{N}_+) = 1$ and hence X_N is well defined. We know from our work on independence and conditional probability that the distribution of X_N is the same as the conditional distribution of X given $X \in R$, which by the previous theorem, is uniformly distributed on R .

Suppose in particular that S is a Cartesian product of n bounded intervals. It turns out to be quite easy to simulate a sequence of independent random variables $\mathbf{X} = (X_1, X_2, \dots)$ each of which is uniformly distributed on S . Thus, the last theorem give an algorithm for simulating a random variable that is uniformly distributed on an irregularly shaped region $R \subseteq S$ (assuming that we have an algorithm for recognizing when a point $x \in \mathbb{R}^n$ falls in R). This method of simulation is known as the *rejection method*, and as we will see in subsequent sections, is more important that might first appear.

Figure 3.2.3: With a sequence of independent, uniformly distributed points in S , the first one to fall in R is uniformly distributed on R .

In the simple probability experiment, random points are uniformly distributed on the rectangular region S . Move and resize the events A and B and note how the probabilities of the 16 events that can be constructed from A and B change. Run the experiment 1000 times and note the agreement between the relative frequencies of the events and the probabilities of the events.

Suppose that (X, Y) is uniformly distributed on the circular region of radius 5, centered at the origin. We can think of (X, Y) as the position of a dart thrown “randomly” at a target. Let $R = \sqrt{X^2 + Y^2}$, the distance from the center to (X, Y) .

1. Give the probability density function of (X, Y) .
2. Find $\mathbb{P}(n \leq R \leq n+1 \text{ for } n \in \{0, 1, 2, 3, 4\})$.

Answer

1. $f(x, y) = \frac{1}{25\pi}$ for $\{(x, y) \in \mathbb{R}^2 : x^2 + y^2 \leq 25\}$
2. $\mathbb{P}(n \leq R \leq n+1) = \frac{2n+1}{25}$ for $n \in \{0, 1, 2, 3, 4\}$

Suppose that (X, Y, Z) is uniformly distributed on the cube $S = [0, 1]^3$. Find $\mathbb{P}(X < Y < Z)$ in two ways:

1. Using the probability density function.
2. Using a combinatorial argument.

Answer

1. $\mathbb{P}(X < Y < Z) = \int_0^1 \int_0^z \int_0^y 1 \, dx \, dy \, dz = \frac{1}{6}$
2. Each of the 6 strict orderings of (X, Y, Z) are equally likely, so $\mathbb{P}(X < Y < Z) = \frac{1}{6}$

The time T (in minutes) required to perform a certain job is uniformly distributed over the interval $[15, 60]$

1. Find the probability that the job requires more than 30 minutes
2. Given that the job is not finished after 30 minutes, find the probability that the job will require more than 15 additional minutes.

Answer

1. $\frac{2}{3}$
2. $\frac{1}{6}$

Data Analysis Exercises

If D is a data set from a variable X with a continuous distribution, then an *empirical density function* can be computed by partitioning the data range into subsets of small size, and then computing the probability density of points in each subset. Empirical probability density functions are studied in more detail in the chapter on Random Samples.

For the cicada data, BW denotes body weight (in grams), BL body length (in millimeters), and G gender (0 for female and 1 for male). Construct an empirical density function for each of the following and display each as a bar graph:

1. BW
2. BL
3. BW given $G = 0$

Answer

1.	BW	(0, 0.1]	(0.1, 0.2]	(0.2, 0.3]	(0.3, 0.4]
	Density	0.8654	5.8654	3.0769	0.1923
2.	BL	(15, 29]	(20, 25]	(25, 30]	(30, 35]
	Density	0.0058	0.1577	0.0346	0.0019
3.	BW	(0, 0.1]	(0.1, 0.2]	(0.2, 0.3]	(0.3, 0.4]

3.3: Mixed Distributions

In the previous two sections, we studied discrete probability measures and continuous probability measures. In this section, we will study probability measures that are combinations of the two types. Once again, if you are a new student of probability you may want to skip the technical details.

Basic Theory

Definitions and Basic Properties

Our starting point is a random experiment modeled by a probability space $(S, \mathcal{S}, \mathbb{P})$. So to review, S is the set of outcomes, \mathcal{S} the collection of events, and \mathbb{P} the probability measure on the sample space (S, \mathcal{S}) . We use the terms *probability measure* and *probability distribution* synonymously in this text. Also, since we use a general definition of random variable, every probability measure can be thought of as the probability distribution of a random variable, so we can always take this point of view if we like. Indeed, most probability measures naturally have random variables associated with them. Here is the main definition:

The probability measure \mathbb{P} is of *mixed type* if S can be partitioned into events D and C with the following properties:

1. D is countable, $0 < \mathbb{P}(D) < 1$ and $\mathbb{P}(\{x\}) > 0$ for every $x \in D$.
2. $C \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$ and $\mathbb{P}(\{x\}) = 0$ for every $x \in C$.

Details

Recall that the term *partition* means that D and C are disjoint and $S = D \cup C$. As always, the collection of events \mathcal{S} is required to be a σ -algebra. The set C is a measurable subset of \mathbb{R}^n and then the elements of \mathcal{S} have the form $A \cup B$ where $A \subseteq D$ and B is a measurable subset of C . Typically in applications, C is defined by a finite number of inequalities involving elementary functions.

Often the discrete set D is a subset of \mathbb{R}^n also, but that's not a requirement. Note that since D and C are complements, $0 < \mathbb{P}(C) < 1$ also. Thus, part of the distribution is concentrated at points in a discrete set D ; the rest of the distribution is continuously spread over C . In the picture below, the light blue shading is intended to represent a continuous distribution of probability while the darker blue dots are intended to represent points of positive probability.

Figure 3.3.1: A mixed distribution on S

The following result is essentially equivalent to the definition.

Suppose that \mathbb{P} is a probability measure on S of mixed type as in (1).

1. The conditional probability measure $A \mapsto \mathbb{P}(A | D) = \mathbb{P}(A)/\mathbb{P}(D)$ for $A \subseteq D$ is a discrete distribution on D
2. The conditional probability measure $A \mapsto \mathbb{P}(A | C) = \mathbb{P}(A)/\mathbb{P}(C)$ for $A \subseteq C$ is a continuous distribution on C .

Proof

In general, conditional probability measures really are probability measures, so the results are obvious since $\mathbb{P}(\{x\} | D) > 0$ for x in the countable set D , and $\mathbb{P}(\{x\} | C) = 0$ for $x \in C$. From another point of view, \mathbb{P} restricted to subsets of D and \mathbb{P} restricted to subsets of C are both finite measures and so can be normalized to produce probability measures.

Note that

$$\mathbb{P}(A) = \mathbb{P}(D)\mathbb{P}(A | D) + \mathbb{P}(C)\mathbb{P}(A | C), \quad A \in \mathcal{S} \quad (3.3.1)$$

Thus, the probability measure P really is a *mixture* of a discrete distribution and a continuous distribution. Mixtures are studied in more generality in the section on conditional distributions. We can define a function on D that is a *partial probability density*

function for the discrete part of the distribution.

Suppose that \mathbb{P} is a probability measure on S of mixed type as in (1). Let g be the function defined by $g(x) = \mathbb{P}(\{x\})$ for $x \in D$. Then

1. $g(x) \geq 0$ for $x \in D$
2. $\sum_{x \in D} g(x) = \mathbb{P}(D)$
3. $\mathbb{P}(A) = \sum_{x \in A} g(x)$ for $A \subseteq D$

Proof

These results follow from the axioms of probability.

1. $g(x) = \mathbb{P}(\{x\}) \geq 0$ since probabilities are nonnegative.
2. $\sum_{x \in D} g(x) = \sum_{x \in D} \mathbb{P}(\{x\}) = \mathbb{P}(D)$ by countable additivity.
3. $\sum_{x \in A} g(x) = \sum_{x \in A} \mathbb{P}(\{x\}) = \mathbb{P}(A)$ for $A \subseteq D$, again by countable additivity.

Technically, g is a density function with respect to counting measure $\#$ on D , the standard measure used for discrete spaces.

Clearly, the normalized function $x \mapsto g(x)/\mathbb{P}(D)$ is the probability density function of the conditional distribution given D , discussed in (2). Often, the continuous part of the distribution is also described by a partial probability density function.

A *partial probability density function* for the continuous part of \mathbb{P} is a nonnegative function $h : C \rightarrow [0, \infty)$ such that

$$\mathbb{P}(A) = \int_A h(x) dx, \quad A \in \mathcal{C} \quad (3.3.2)$$

Details

Technically, h is required to be measurable, and is a density function with respect to Lebesgue measure λ_n on C , the standard measure on \mathbb{R}^n .

Clearly, the normalized function $x \mapsto h(x)/\mathbb{P}(C)$ is the probability density function of the conditional distribution given C discussed in (2). As with purely continuous distributions, the existence of a probability density function for the continuous part of a mixed distribution is not guaranteed. And when it does exist, a density function for the continuous part is not unique. Note that the values of h could be changed to other nonnegative values on a countable subset of C , and the displayed equation above would still hold, because only *integrals* of h are important. The probability measure \mathbb{P} is completely determined by the partial probability density functions.

Suppose that \mathbb{P} has partial probability density functions g and h for the discrete and continuous parts, respectively. Then

$$\mathbb{P}(A) = \sum_{x \in A \cap D} g(x) + \int_{A \cap C} h(x) dx, \quad A \in \mathcal{S} \quad (3.3.3)$$

Proof

Figure 3.3.2: A mixed distribution is completely determined by its partial density functions.

Truncated Variables

Distributions of mixed type occur naturally when a random variable with a continuous distribution is *truncated* in a certain way. For example, suppose that T is the random lifetime of a device, and has a continuous distribution with probability density function f that is positive on $[0, \infty)$. In a test of the device, we can't wait forever, so we might select a positive constant a and record the random variable U , defined by *truncating* T at a , as follows:

$$U = \begin{cases} T, & T < a \\ a, & T \geq a \end{cases} \quad (3.3.4)$$

U has a mixed distribution. In the notation above,

1. $D = \{a\}$ and $g(a) = \int_a^\infty f(t) dt$
2. $C = [0, a)$ and $h(t) = f(t)$ for $t \in [0, a)$

Suppose next that random variable X has a continuous distribution on \mathbb{R} , with probability density function f that is positive on \mathbb{R} . Suppose also that $a, b \in \mathbb{R}$ with $a < b$. The variable is *truncated* on the interval $[a, b]$ to create a new random variable Y as follows:

$$Y = \begin{cases} a, & X \leq a \\ X, & a < X < b \\ b, & X \geq b \end{cases} \quad (3.3.5)$$

Y has a mixed distribution. In the notation above,

1. $D = \{a, b\}$, $g(a) = \int_{-\infty}^a f(x) dx$, $g(b) = \int_b^\infty f(x) dx$
2. $C = (a, b)$ and $h(x) = f(x)$ for $x \in (a, b)$

Another way that a “mixed” probability distribution can occur is when we have a pair of random variables (X, Y) for our experiment, one with a discrete distribution and the other with a continuous distribution. This setting is explored in the next section on Joint Distributions.

Examples and Applications

Suppose that X has probability $\frac{1}{2}$ uniformly distributed on the set $\{1, 2, \dots, 8\}$ and has probability $\frac{1}{2}$ uniformly distributed on the interval $[0, 10]$. Find $\mathbb{P}(X > 6)$.

Answer

$$\frac{13}{40}$$

Suppose that (X, Y) has probability $\frac{1}{3}$ uniformly distributed on $\{0, 1, 2\}^2$ and has probability $\frac{2}{3}$ uniformly distributed on $[0, 2]^2$. Find $\mathbb{P}(Y > X)$.

Answer

$$\frac{4}{9}$$

Suppose that the lifetime T of a device (in 1000 hour units) has the exponential distribution with probability density function $f(t) = e^{-t}$ for $0 \leq t < \infty$. A test of the device is terminated after 2000 hours; the truncated lifetime U is recorded. Find each of the following:

1. $\mathbb{P}(U < 1)$
2. $\mathbb{P}(U = 2)$

Answer

1. $1 - e^{-1} \approx 0.6321$
2. $e^{-2} \approx 0.1353$

3.4: Joint Distributions

The purpose of this section is to study how the distribution of a pair of random variables is related to the distributions of the variables individually. If you are a new student of probability you may want to skip the technical details.

Basic Theory

Joint and Marginal Distributions

As usual, we start with a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} is the collection of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . Suppose now that X and Y are random variables for the experiment, and that X takes values in S while Y takes values in T . We can think of (X, Y) as a random variable taking values in the product set $S \times T$. The purpose of this section is to study how the distribution of (X, Y) is related to the distributions of X and Y individually.

Recall that

1. The distribution of (X, Y) is the probability measure on $S \times T$ given by $\mathbb{P}[(X, Y) \in C]$ for $C \subseteq S \times T$.
2. The distribution of X is the probability measure on S given by $\mathbb{P}(X \in A)$ for $A \subseteq S$.
3. The distribution of Y is the probability measure on T given by $\mathbb{P}(Y \in B)$ for $B \subseteq T$.

In this context, the distribution of (X, Y) is called the *joint distribution*, while the distributions of X and of Y are referred to as *marginal distributions*.

Details

The sets S and T come with σ -algebras of admissible subsets \mathcal{S} and \mathcal{T} , respectively, just as the collection of events \mathcal{F} is a σ -algebra. The Cartesian product set $S \times T$ is given the product σ -algebra $\mathcal{S} \otimes \mathcal{T}$ generated by products $A \times B$ where $A \in \mathcal{S}$ and $B \in \mathcal{T}$. The random variables X and Y are measurable, which ensures that (X, Y) is also a random variable (that is, measurable). Moreover, the distribution of (X, Y) is uniquely determined by probabilities of the form $\mathbb{P}[(X, Y) \in A \times B] = \mathbb{P}(X \in A, Y \in B)$ where $A \in \mathcal{S}$ and $B \in \mathcal{T}$. As usual the spaces (S, \mathcal{S}) and (T, \mathcal{T}) each fall into the two classes we have studied in the previous sections:

1. *Discrete*: the set is countable and the σ -algebra consists of all subsets.
2. *Euclidean*: the set is a measurable subset of \mathbb{R}^n for some $n \in \mathbb{N}_+$ and the σ -algebra consists of the measurable subsets.

The first simple but very important point, is that the marginal distributions can be obtained from the joint distribution.

Note that

1. $\mathbb{P}(X \in A) = \mathbb{P}[(X, Y) \in A \times T]$ for $A \subseteq S$
2. $\mathbb{P}(Y \in B) = \mathbb{P}[(X, Y) \in S \times B]$ for $B \subseteq T$

The converse does not hold in general. The joint distribution contains much more information than the marginal distributions separately. However, the converse does hold if X and Y are independent, as we will show [below](#).

Joint and Marginal Densities

Recall that probability distributions are often described in terms of probability density functions. Our goal is to study how the probability density functions of X and Y individually are related to probability density function of (X, Y) . But first we need to make sure that we understand our starting point.

We assume that (X, Y) has density function $f : S \times T \rightarrow (0, \infty)$ in the following sense:

1. If X and Y have discrete distributions on the countable sets S and T respectively, then f is defined by

$$f(x, y) = \mathbb{P}(X = x, Y = y), \quad (x, y) \in S \times T \quad (3.4.1)$$

2. If X and Y have continuous distributions on $S \subseteq \mathbb{R}^j$ and $T \subseteq \mathbb{R}^k$ respectively, then f is defined by the condition

$$\mathbb{P}[(X, Y) \in C] = \int_C f(x, y) d(x, y), \quad C \subseteq S \times T \quad (3.4.2)$$

3. In the mixed case where X has a discrete distribution on the countable set S and Y has a continuous distribution on $T \subseteq \mathbb{R}^k$, then f is defined by the condition

$$\mathbb{P}(X = x, Y \in B) = \int_B f(x, y) dy, \quad x \in S, B \subseteq T \quad (3.4.3)$$

4. In the mixed case where X has a continuous distribution on $S \subseteq \mathbb{R}^j$ and Y has a discrete distribution on the countable set T , then f is defined by the condition

$$\mathbb{P}(X \in A, Y = y) = \int_A f(x, y), dx, \quad A \subseteq S, y \in T \quad (3.4.4)$$

Details

1. In this case, (X, Y) has a discrete distribution on the countable set $S \times T$ and f is the density function with respect to counting measure $\#$ on $S \times T$.
2. In this case, (X, Y) has a continuous distribution on $S \times T \subseteq \mathbb{R}^{j+k}$ and f is the density function with respect to Lebesgue measure λ_{j+k} on $S \times T$. Lebesgue measure, named for Henri Lebesgue is the standard measure on Euclidean spaces.
3. In this case, (X, Y) actually has a continuous distribution:

$$\mathbb{P}[(X, Y) = (x, y)] = \mathbb{P}(X = x, Y = y) \leq \mathbb{P}(Y = y) = 0, \quad (x, y) \in S \times T \quad (3.4.5)$$

The function f is the density function with respect to the product measure formed from counting measure $\#$ on S and Lebesgue measure λ_k on T .

4. This case is just like (c) but with the roles of S and T reversed. Once again, (X, Y) has a continuous distribution and f is the density function with respect to the product measure on $S \times T$ formed by Lebesgue measure λ_j on S and counting measure $\#$ on T .

In cases (b), (c), and (d), the existence of a probability density function is not guaranteed, but is an assumption that we are making. All four cases (and many others) can be unified under the general theories of measure and integration.

First we will see how to obtain the probability density function of one variable when the other has a discrete distribution.

Suppose that (X, Y) has probability density function f as described [above](#).

1. If Y has a discrete distribution on the countable set T , then X has probability density function g given by $g(x) = \sum_{y \in T} f(x, y)$ for $x \in S$
2. If X has a discrete distribution on the countable set S , then Y has probability density function h given by $h(y) = \sum_{x \in S} f(x, y)$, $y \in T$

Proof

The two results are symmetric, so we will prove (a). The main tool is the countable additivity property of probability. Suppose first that X also has a discrete distribution on the countable set S . Then for $x \in S$,

$$g(x) = \mathbb{P}(X = x) = \mathbb{P}(X = x, Y \in T) = \sum_{y \in T} \mathbb{P}(X = x, Y = y) = \sum_{y \in T} f(x, y) \quad (3.4.6)$$

Suppose next that X has a continuous distribution on $S \subseteq \mathbb{R}^j$. Then for $A \subseteq \mathbb{R}^j$,

$$\mathbb{P}(X \in A) = \mathbb{P}(X \in A, Y \in T) = \sum_{y \in T} \mathbb{P}(X \in A, Y = y) = \sum_{y \in T} \int_A f(x, y) dx = \int_A \sum_{y \in T} f(x, y), dx \quad (3.4.7)$$

The interchange of sum and integral is allowed since f is nonnegative. By the meaning of the term, X has probability density function g given by $g(x) = \sum_{y \in T} f(x, y)$ for $x \in S$

Next we will see how to obtain the probability density function of one variable when the other has a continuous distribution.

Suppose again that (X, Y) has probability density function f as described [above](#).

1. If Y has a continuous distribution on $T \subseteq \mathbb{R}^k$ then X has probability density function g given by $g(x) = \int_T f(x, y) dy$, $x \in S$
2. If X has a continuous distribution on $S \subseteq \mathbb{R}^j$ then Y has probability density function h given by $h(y) = \int_S f(x, y) dx$, $y \in T$

Proof

Again, the results are symmetric, so we show (a). Suppose first that X has a discrete distribution on the countable set S . Then for $x \in S$

$$g(x) = \mathbb{P}(X = x) = \mathbb{P}(X = x, Y \in T) = \int_T f(x, y) dy \quad (3.4.8)$$

Next suppose that X has a continuous distribution on $S \subseteq \mathbb{R}^j$. Then for $A \subseteq S$,

$$\mathbb{P}(X \in A) = \mathbb{P}(X \in A, Y \in T) = \mathbb{P}[(X, Y) \in A \times T] = \int_{A \times T} f(x, y) d(x, y) = \int_A \int_T f(x, y) dy \quad (3.4.9)$$

Hence by the very meaning of the term, X has probability density function g given by $g(x) = \int_T f(x, y) dy$ for $x \in S$. Writing the double integral as an iterated integral is a special case of Fubini's theorem, named for Guido Fubini.

In the context of the previous two theorems, f is called the *joint probability density function* of (X, Y) , while g and h are called the *marginal density functions* of X and of Y , respectively. Some of the [computational exercises](#) below will make the term *marginal* clear.

Independence

When the variables are independent, the marginal distributions determine the joint distribution.

If X and Y are independent, then the distribution of X and the distribution of Y determine the distribution of (X, Y) .

Proof

If X and Y are independent then,

$$\mathbb{P}[(X, Y) \in A \times B] = \mathbb{P}(X \in A, Y \in B) = \mathbb{P}(X \in A)\mathbb{P}(Y \in B) \quad A \in \mathcal{S}, B \in \mathcal{T} \quad (3.4.10)$$

and as noted in the details for (1), this completely determines the distribution (X, Y) on $S \times T$.

When the variables are independent, the joint density is the product of the marginal densities.

Suppose that X and Y are independent and have probability density function g and h respectively. Then (X, Y) has probability density function f given by

$$f(x, y) = g(x)h(y), \quad (x, y) \in S \times T \quad (3.4.11)$$

Proof

The main tool is the fact that an event defined in terms of X is independent of an event defined in terms of Y .

1. Suppose that X and Y have discrete distributions on the countable sets S and T respectively. Then for $(x, y) \in S \times T$,

$$\mathbb{P}[(X, Y) = (x, y)] = \mathbb{P}(X = x, Y = y) = \mathbb{P}(X = x)\mathbb{P}(Y = y) = g(x)h(y) \quad (3.4.12)$$

2. Suppose next that X and Y have continuous distributions on $S \subseteq \mathbb{R}^j$ and $T \subseteq \mathbb{R}^k$ respectively. Then for $A \subseteq S$ and $B \subseteq T$.

$$\mathbb{P}[(X, Y) \in A \times B] = \mathbb{P}(X \in A, Y \in B) = \mathbb{P}(X \in A)\mathbb{P}(Y \in B) = \int_A g(x) dx \int_B h(y) dy = \int_{A \times B} g(x)h(y) d(x, y) \quad (3.4.13)$$

As noted in the details for (1), a probability measure on $S \times T$ is completely determined by its values on product sets, so it follows that $\mathbb{P}[(X, Y) \in C] = \int_C f(x, y) d(x, y)$ for general $C \subseteq S \times T$. Hence (X, Y) has PDF f .

3. Suppose next that X has a discrete distribution on the countable set S and that Y has a continuous distribution on $T \subseteq \mathbb{R}^k$. If $x \in S$ and $B \subseteq T$,

$$\mathbb{P}(X = x, Y \in B) = \mathbb{P}(X = x)\mathbb{P}(Y \in B) = g(x) \int_B h(y) dy = \int_B g(x)h(y) dy \quad (3.4.14)$$

so again it follows that (X, Y) has PDF f . The case where X has a continuous distribution on $S \subseteq \mathbb{R}^j$ and Y has a discrete distribution on the countable set T is analogous.

The following result gives a converse to the [last result](#). If the joint probability density factors into a function of x only and a function of y only, then X and Y are independent, and we can *almost* identify the individual probability density functions just from the factoring.

Factoring Theorem. Suppose that (X, Y) has probability density function f of the form

$$f(x, y) = u(x)v(y), \quad (x, y) \in S \times T \quad (3.4.15)$$

where $u: S \rightarrow [0, \infty)$ and $v: T \rightarrow [0, \infty)$. Then X and Y are independent, and there exists a positive constant c such that X and Y have probability density functions g and h , respectively, given by

$$g(x) = c u(x), \quad x \in S \quad (3.4.16)$$

$$h(y) = \frac{1}{c} v(y), \quad y \in T \quad (3.4.17)$$

Proof

Note that the proofs in the various cases are essentially the same, except for sums in the discrete case and integrals in the continuous case.

1. Suppose that X and Y have discrete distributions on the countable sets S and T , respectively, so that (X, Y) has a discrete distribution on $S \times T$. In this case, the assumption is

$$\mathbb{P}(X = x, Y = y) = u(x)v(y), \quad (x, y) \in S \times T \quad (3.4.18)$$

Summing over $y \in T$ in the displayed equation gives $g(x) = \mathbb{P}(X = x) = cu(x)$ for $x \in S$ where $c = \sum_{y \in T} v(y)$. Similarly, summing over $x \in S$ in the displayed equation gives $h(y) = \mathbb{P}(Y = y) = kv(y)$ for $y \in T$ where $k = \sum_{x \in S} u(x)$. Summing over $(x, y) \in S \times T$ in the displayed equation gives $1 = ck$ so $k = 1/c$. Finally, substituting gives $\mathbb{P}(X = x, Y = y) = \mathbb{P}(X = x)\mathbb{P}(Y = y)$ for $(x, y) \in S \times T$ so X and Y are independent.

2. Suppose next that X and Y have continuous distributions on $S \subseteq \mathbb{R}^j$ and $T \subseteq \mathbb{R}^k$ respectively. For $A \subseteq S$ and $B \subseteq T$,

$$\mathbb{P}(X \in A, Y \in B) = \mathbb{P}[(X, Y) \in A \times B] = \int_{A \times B} f(x, y) d(x, y) = \int_A u(x) dx \int_B v(y) dy \quad (3.4.19)$$

Letting $B = T$ in the displayed equation gives $\mathbb{P}(X \in A) = \int_A c u(x) dx$ for $A \subseteq S$, where $c = \int_T v(y) dy$. By definition, X has PDF $g = c u$. Next, letting $A = S$ in the displayed equation gives $\mathbb{P}(Y \in B) = \int_B k v(y) dy$ for $B \subseteq T$, where $k = \int_S u(x) dx$. Thus, Y has PDF $g = k v$. Next, letting $A = S$ and $B = T$ in the displayed equation gives $1 = c k$, so $k = 1/c$. Now note that the displayed equation holds with u replaced by g and v replaced by h , and this in turn gives $\mathbb{P}(X \in A, Y \in B) = \mathbb{P}(X \in A)\mathbb{P}(Y \in B)$, so X and Y are independent.

3. Suppose next that X has a discrete distribution on the countable set S and that Y has a continuous distributions on $T \subseteq \mathbb{R}^k$. For $x \in S$ and $B \subseteq T$,

$$\mathbb{P}(X = x, Y \in B) = \int_B f(x, y) dy = u(x) \int_B v(y) dy \quad (3.4.20)$$

Letting $B = T$ in the displayed equation gives $\mathbb{P}(X = x) = c u(x)$ for $x \in S$, where $c = \int_T v(y) dy$. So X has PDF $g = c u$. Next, summing over $x \in S$ in the displayed equation gives $\mathbb{P}(Y \in B) = k \int_B v(y) dy$ for $B \subseteq T$, where $k = \sum_{x \in S} u(x)$. Thus, Y has PDF $g = k v$. Next, summing over $x \in S$ and letting $B = T$ in the displayed equation gives $1 = c k$, so $k = 1/c$. Now note that the displayed equation holds with u replaced by g and v replaced by h , and this in turn gives $\mathbb{P}(X = x, Y \in B) = \mathbb{P}(X = x)\mathbb{P}(Y \in B)$, so X and Y are independent. The case where X has a continuous distribution on $S \subseteq \mathbb{R}^j$ and Y has a discrete distribution on the countable set T is analogous.

The last two results extend to more than two random variables, because X and Y themselves may be random vectors. Here is the explicit statement:

Suppose that X_i is a random variable taking values in a set R_i with probability density function g_i for $i \in \{1, 2, \dots, n\}$, and that the random variables are independent. Then the random vector $\mathbf{X} = (X_1, X_2, \dots, X_n)$ taking values in $S = R_1 \times R_2 \times \dots \times R_n$ has probability density function f given by

$$f(x_1, x_2, \dots, x_n) = g_1(x_1)g_2(x_2) \cdots g_n(x_n), \quad (x_1, x_2, \dots, x_n) \in S \quad (3.4.21)$$

The special case where the distributions are all the same is particularly important.

Suppose that $\mathbf{X} = (X_1, X_2, \dots, X_n)$ is a sequence of independent random variables, each taking values in a set R and with common probability density function g . Then the probability density function f of \mathbf{X} on $S = R^n$ is given by

$$f(x_1, x_2, \dots, x_n) = g(x_1)g(x_2) \cdots g(x_n), \quad (x_1, x_2, \dots, x_n) \in S \quad (3.4.22)$$

In probability jargon, \mathbf{X} is a sequence of *independent, identically distributed* variables, a phrase that comes up so often that it is often abbreviated as *IID*. In statistical jargon, \mathbf{X} is a *random sample* of size n from the common distribution. As is evident from the special terminology, this situation is very important in both branches of mathematics. In statistics, the joint probability density function f plays an important role in procedures such as maximum likelihood and the identification of uniformly best estimators.

Recall that (mutual) independence of random variables is a very strong property. If a collection of random variables is independent, then any subcollection is also independent. New random variables formed from disjoint subcollections are independent. For a simple example, suppose that X , Y , and Z are independent real-valued random variables. Then

1. $\sin(X)$, $\cos(Y)$, and e^Z are independent.
2. (X, Y) and Z are independent.
3. $X^2 + Y^2$ and $\arctan(Z)$ are independent.
4. X and Z are independent.
5. Y and Z are independent.

In particular, note that statement 2 in the list above is much stronger than the conjunction of statements 4 and 5. Restated, if X and Z are dependent, then (X, Y) and Z are also dependent.

Examples and Applications

Dice

Recall that a *standard die* is an ordinary six-sided die, with faces numbered from 1 to 6. The answers in the next couple of exercises give the joint distribution in the body of a table, with the marginal distributions literally in the margins. Such tables are the reason for the term *marginal distribution*.

Suppose that two standard, fair dice are rolled and the sequence of scores (X_1, X_2) recorded. Our usual assumption is that the variables X_1 and X_2 are independent. Let $Y = X_1 + X_2$ and $Z = X_1 - X_2$ denote the sum and difference of the scores, respectively.

1. Find the probability density function of (Y, Z) .

- Find the probability density function of Y .
- Find the probability density function of Z .
- Are Y and Z independent?

Answer

Let f denote the PDF of (Y, Z) , g the PDF of Y and h the PDF of Z . The PDFs are given in the following table. Random variables Y and Z are dependent

$f(y, z)$	$y = 2$	3	4	5	6	7	8	9	0	11	12	$h(z)$
$z = -5$	0	0	0	0	0	$\frac{1}{36}$	0	0	0	0	0	$\frac{1}{36}$
-4	0	0	0	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	0	0	0	$\frac{2}{36}$
-3	0	0	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	0	0	$\frac{3}{36}$
-2	0	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	0	$\frac{4}{36}$
-1	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{5}{36}$
0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	$\frac{6}{36}$
1	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{5}{36}$
2	0	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	$\frac{1}{36}$	0	0	$\frac{4}{36}$

5	0	0	0	0	0	$\frac{1}{36}$	0	0	0	0	0	$\frac{1}{36}$
$g(y)$	$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$	1

Suppose that two standard, fair dice are rolled and the sequence of scores (X_1, X_2) recorded. Let $U = \min\{X_1, X_2\}$ and $V = \max\{X_1, X_2\}$ denote the minimum and maximum scores, respectively.

- Find the probability density function of (U, V) .
- Find the probability density function of U .
- Find the probability density function of V .
- Are U and V independent?

Answer

Let f denote the PDF of (U, V) , g the PDF of U , and h the PDF of V . The PDFs are given in the following table. Random variables U and V are dependent.

$f(u, v)$	$u = 1$	2	3	4	5	6	$h(v)$
$v = 1$	$\frac{1}{36}$	0	0	0	0	0	$\frac{1}{36}$
2	$\frac{2}{36}$	$\frac{1}{36}$	0	0	0	0	$\frac{3}{36}$
3	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{1}{36}$	0	0	0	$\frac{5}{36}$
4	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{1}{36}$	0	0	$\frac{7}{36}$
5	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{1}{36}$	0	$\frac{9}{36}$
6	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{2}{36}$	$\frac{1}{36}$	$\frac{11}{36}$
$g(u)$	$\frac{11}{36}$	$\frac{9}{36}$	$\frac{7}{36}$	$\frac{5}{36}$	$\frac{3}{36}$	$\frac{1}{36}$	1

The previous two exercises show clearly how little information is given with the marginal distributions compared to the joint distribution. With the marginal PDFs alone, you could not even determine the support set of the joint distribution, let alone the values of the joint PDF.

Simple Continuous Distributions

Suppose that (X, Y) has probability density function f given by $f(x, y) = x + y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.

1. Find the probability density function of X .
2. Find the probability density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = x + \frac{1}{2}$ for $0 \leq x \leq 1$
2. Y has PDF h given by $h(y) = y + \frac{1}{2}$ for $0 \leq y \leq 1$
3. X and Y are dependent.

Suppose that (X, Y) has probability density function f given by $f(x, y) = 2(x + y)$ for $0 \leq x \leq y \leq 1$.

1. Find the probability density function of X .
2. Find the probability density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = (1 + 3x)(1 - x)$ for $0 \leq x \leq 1$.
2. Y has PDF h given by $h(y) = 3y^2$ for $0 \leq y \leq 1$.
3. X and Y are dependent.

Suppose that (X, Y) has probability density function f given by $f(x, y) = 6x^2y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.

1. Find the probability density function of X .
2. Find the probability density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = 3x^2$ for $0 \leq x \leq 1$.
2. Y has PDF h given by $h(y) = 2y$ for $0 \leq y \leq 1$.
3. X and Y are independent.

The last exercise is a good illustration of the [factoring theorem](#). Without any work at all, we can tell that the PDF of X is proportional to $x \mapsto x^2$ on the interval $[0, 1]$, the PDF of Y is proportional to $y \mapsto y$ on the interval $[0, 1]$, and that X and Y are independent. The only thing unclear is how the constant 6 factors.

Suppose that (X, Y) has probability density function f given by $f(x, y) = 15x^2y$ for $0 \leq x \leq y \leq 1$.

1. Find the probability density function of X .
2. Find the probability density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = \frac{15}{2}x^2(1 - x^2)$ for $0 \leq x \leq 1$.
2. Y has PDF h given by $h(y) = 5y^4$ for $0 \leq y \leq 1$.
3. X and Y are dependent.

Note that in the last exercise, the [factoring theorem](#) does not apply. Random variables X and Y each take values in $[0, 1]$, but the joint PDF factors only on part of $[0, 1]^2$.

Suppose that (X, Y, Z) has probability density function f given $f(x, y, z) = 2(x + y)z$ for $0 \leq x \leq 1, 0 \leq y \leq 1, 0 \leq z \leq 1$.

1. Find the probability density function of each pair of variables.
2. Find the probability density function of each variable.
3. Determine the dependency relationships between the variables.

Proof

1. (X, Y) has PDF $f_{1,2}$ given by $f_{1,2}(x, y) = x + y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.
2. (X, Z) has PDF $f_{1,3}$ given by $f_{1,3}(x, z) = 2z(x + \frac{1}{2})$ for $0 \leq x \leq 1, 0 \leq z \leq 1$.
3. (Y, Z) has PDF $f_{2,3}$ given by $f_{2,3}(y, z) = 2z(y + \frac{1}{2})$ for $0 \leq y \leq 1, 0 \leq z \leq 1$.
4. X has PDF f_1 given by $f_1(x) = x + \frac{1}{2}$ for $0 \leq x \leq 1$.
5. Y has PDF f_2 given by $f_2(y) = y + \frac{1}{2}$ for $0 \leq y \leq 1$.
6. Z has PDF f_3 given by $f_3(z) = 2z$ for $0 \leq z \leq 1$.
7. Z and (X, Y) are independent; X and Y are dependent.

Suppose that (X, Y) has probability density function f given by $f(x, y) = 2e^{-x}e^{-y}$ for $0 \leq x \leq y < \infty$.

1. Find the probability density function of X .
2. Find the probability density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = 2e^{-2x}$ for $0 \leq x < \infty$.
2. Y has PDF h given by $h(y) = 2(e^{-y} - e^{-2y})$ for $0 \leq y < \infty$.
3. X and Y are dependent.

In the previous exercise, X has an *exponential distribution* with rate parameter 2. Recall that exponential distributions are widely used to model random times, particularly in the context of the Poisson model.

Suppose that X and Y are independent, and that X has probability density function g given by $g(x) = 6x(1-x)$ for $0 \leq x \leq 1$, and that Y has probability density function h given by $h(y) = 12y^2(1-y)$ for $0 \leq y \leq 1$.

1. Find the probability density function of (X, Y) .
2. Find $\mathbb{P}(X + Y \leq 1)$.

Answer

1. (X, Y) has PDF f given by $f(x, y) = 72x(1-x)y^2(1-y)$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.
2. $\mathbb{P}(X + Y \leq 1) = \frac{13}{35}$

In the previous exercise, X and Y have *beta distributions*, which are widely used to model random probabilities and proportions. Beta distributions are studied in more detail in the chapter on Special Distributions.

Suppose that Θ and Φ are independent random angles, with common probability density function g given by $g(t) = \sin(t)$ for $0 \leq t \leq \frac{\pi}{2}$.

1. Find the probability density function of (Θ, Φ) .
2. Find $\mathbb{P}(\Theta \leq \Phi)$.

Answer

1. (Θ, Φ) has PDF f given by $f(\theta, \phi) = \sin(\theta)\sin(\phi)$ for $0 \leq \theta \leq \frac{\pi}{2}, 0 \leq \phi \leq \frac{\pi}{2}$.
2. $\mathbb{P}(\Theta \leq \Phi) = \frac{1}{2}$

The common distribution of X and Y in the previous exercise governs a random angle in Bertrand's problem.

Suppose that X and Y are independent, and that X has probability density function g given by $g(x) = \frac{2}{x^3}$ for $1 \leq x < \infty$, and that Y has probability density function h given by $h(y) = \frac{3}{y^4}$ for $1 \leq y < \infty$.

1. Find the probability density function of (X, Y) .
2. Find $\mathbb{P}(X \leq Y)$.

Answer

1. (X, Y) has PDF f given by $f(x, y) = \frac{6}{x^3y^4}$ for $1 \leq x < \infty, 1 \leq y < \infty$.
2. $\mathbb{P}(X \leq Y) = \frac{2}{5}$

Both X and Y in the previous exercise have *Pareto distributions*, named for Vilfredo Pareto. Recall that Pareto distributions are used to model certain economic variables and are studied in more detail in the chapter on Special Distributions.

Suppose that (X, Y) has probability density function g given by $g(x, y) = 15x^2y$ for $0 \leq x \leq y \leq 1$, and that Z has probability density function h given by $h(z) = 4z^3$ for $0 \leq z \leq 1$, and that (X, Y) and Z are independent.

1. Find the probability density function of (X, Y, Z) .
2. Find the probability density function of (X, Z) .
3. Find the probability density function of (Y, Z) .
4. Find $\mathbb{P}(Z \leq XY)$.

Answer

1. (X, Y, Z) has PDF f given by $f(x, y, z) = 60x^2yz^3$ for $0 \leq x \leq y \leq 1, 0 \leq z \leq 1$.
2. (X, Z) has PDF $f_{1,3}$ given by $f_{1,3}(x, z) = 30x^2(1-x^2)z^3$ for $0 \leq x \leq 1, 0 \leq z \leq 1$.
3. (Y, Z) has PDF $f_{2,3}$ given by $f_{2,3}(y, z) = 20y^4z^3$ for $0 \leq y \leq 1, 0 \leq z \leq 1$.
4. $\mathbb{P}(Z \leq XY) = \frac{15}{92}$

Multivariate Uniform Distributions

Multivariate uniform distributions give a geometric interpretation of some of the concepts in this section.

Recall first that for $n \in \mathbb{N}_+$, the standard measure on \mathbb{R}^n is

$$\lambda_n(A) = \int_A 1 dx, \quad A \subseteq \mathbb{R}^n \quad (3.4.23)$$

In particular, $\lambda_1(A)$ is the length of $A \subseteq \mathbb{R}$, $\lambda_2(A)$ is the area of $A \subseteq \mathbb{R}^2$, and $\lambda_3(A)$ is the volume of $A \subseteq \mathbb{R}^3$.

Details

Technically λ_n is Lebesgue measure on the measurable subsets of \mathbb{R}^n . The integral representation is valid for the types of sets that occur in applications. In the discussion below, all subsets are assumed to be measurable.

Suppose now that X takes values in \mathbb{R}^j , Y takes values in \mathbb{R}^k , and that (X, Y) is *uniformly distributed* on a set $R \subseteq \mathbb{R}^{j+k}$. So $0 < \lambda_{j+k}(R) < \infty$ and the joint probability density function f of (X, Y) is given by $f(x, y) = 1/\lambda_{j+k}(R)$ for $(x, y) \in R$. Recall that uniform distributions *always* have constant density functions. Now let S and T be the projections of R onto \mathbb{R}^j and \mathbb{R}^k respectively, defined as follows:

$$S = \{x \in \mathbb{R}^j : (x, y) \in R \text{ for some } y \in \mathbb{R}^k\}, \quad T = \{y \in \mathbb{R}^k : (x, y) \in R \text{ for some } x \in \mathbb{R}^j\} \quad (3.4.24)$$

Note that $R \subseteq S \times T$. Next we denote the cross sections at $x \in S$ and at $y \in T$, respectively by

$$T_x = \{t \in T : (x, t) \in R\}, \quad S_y = \{s \in S : (s, y) \in R\} \quad (3.4.25)$$

Figure 3.4.1: The projections S and T , and the cross sections at x and y

X takes values in S and Y takes values in T . The probability density functions g and h of X and Y are proportional to the cross-sectional measures:

1. $g(x) = \lambda_k(T_x) / \lambda_{j+k}(R)$ for $x \in S$
2. $h(y) = \lambda_j(S_y) / \lambda_{j+k}(R)$ for $y \in T$

Proof

From our general theory, X has PDF g given by

$$g(x) = \int_{T_x} f(x, y) dy = \int_{T_x} \frac{1}{\lambda_{j+k}(R)} dy = \frac{\lambda_k(T_x)}{\lambda_{j+k}(R)}, \quad x \in S \quad (3.4.26)$$

Technically, it's possible that $\lambda_k(T_x) = \infty$ for some $x \in S$, but the set of such x has measure 0. That is, $\lambda_j\{x \in S : \lambda_k(T_x) = \infty\} = 0$. The result for Y is analogous.

In particular, note from previous theorem that X and Y are neither independent nor uniformly distributed in general. However, these properties *do* hold if R is a Cartesian product set.

Suppose that $R = S \times T$.

1. X is uniformly distributed on S .
2. Y is uniformly distributed on T .
3. X and Y are independent.

Proof

In this case, $T_x = T$ and $S_y = S$ for every $x \in S$ and $y \in T$. Also, $\lambda_{j+k}(R) = \lambda_j(S)\lambda_k(T)$, so for $x \in S$ and $y \in T$, $f(x, y) = 1/[\lambda_j(S)\lambda_k(T)]$, $g(x) = 1/\lambda_j(S)$, $h(y) = 1/\lambda_k(T)$.

In each of the following cases, find the joint and marginal probability density functions, and determine if X and Y are independent.

1. (X, Y) is uniformly distributed on the square $R = [-6, 6]^2$.
2. (X, Y) is uniformly distributed on the triangle $R = \{(x, y) : -6 \leq y \leq x \leq 6\}$.

3. (X, Y) is uniformly distributed on the circle $R = \{(x, y) : x^2 + y^2 \leq 36\}$.

Answer

In the following, f is the PDF of (X, Y) , g the PDF of X , and h the PDF of Y .

1.
 - $f(x, y) = \frac{1}{144}$ for $-6 \leq x \leq 6, -6 \leq y \leq 6$
 - $g(x) = \frac{1}{12}$ for $-6 \leq x \leq 6$
 - $h(y) = \frac{1}{12}$ for $-6 \leq y \leq 6$
 - X and Y are independent.
2.
 - $f(x, y) = \frac{1}{72}$ for $-6 \leq y \leq x \leq 6$
 - $g(x) = \frac{1}{72}(x+6)$ for $-6 \leq x \leq 6$
 - $h(y) = \frac{1}{72}(y+6)$ for $-6 \leq y \leq 6$
 - X and Y are dependent.
3.
 - $f(x, y) = \frac{1}{36\pi}$ for $x^2 + y^2 \leq 36$
 - $g(x) = \frac{1}{18\pi}\sqrt{36-x^2}$ for $-6 \leq x \leq 6$
 - $h(y) = \frac{1}{18\pi}\sqrt{36-y^2}$ for $-6 \leq y \leq 6$
 - X and Y are dependent.

In the bivariate uniform experiment, run the simulation 1000 times for each of the following cases. Watch the points in the scatter plot and the graphs of the marginal distributions. Interpret what you see in the context of the discussion above.

1. square
2. triangle
3. circle

Suppose that (X, Y, Z) is uniformly distributed on the cube $[0, 1]^3$.

1. Give the joint probability density function of (X, Y, Z) .
2. Find the probability density function of each pair of variables.
3. Find the probability density function of each variable
4. Determine the dependency relationships between the variables.

Answer

1. (X, Y, Z) has PDF f given by $f(x, y, z) = 1$ for $0 \leq x \leq 1, 0 \leq y \leq 1, 0 \leq z \leq 1$ (the uniform distribution on $[0, 1]^3$)
2. (X, Y) , (X, Z) , and (Y, Z) have common PDF g given by $g(u, v) = 1$ for $0 \leq u \leq 1, 0 \leq v \leq 1$ (the uniform distribution on $[0, 1]^2$)
3. X, Y , and Z have common PDF h given by $h(u) = 1$ for $0 \leq u \leq 1$ (the uniform distribution on $[0, 1]$)
4. X, Y, Z are independent.

Suppose that (X, Y, Z) is uniformly distributed on $\{(x, y, z) : 0 \leq x \leq y \leq z \leq 1\}$.

1. Give the joint density function of (X, Y, Z) .
2. Find the probability density function of each pair of variables.
3. Find the probability density function of each variable
4. Determine the dependency relationships between the variables.

Answer

1. (X, Y, Z) has PDF f given by $f(x, y, z) = 6$ for $0 \leq x \leq y \leq z \leq 1$
2.
 - (X, Y) has PDF $f_{1,2}$ given by $f_{1,2}(x, y) = 6(1-y)$ for $0 \leq x \leq y \leq 1$
 - (X, Z) has PDF $f_{1,3}$ given by $f_{1,3}(x, z) = 6(z-x)$ for $0 \leq x \leq z \leq 1$
 - (Y, Z) has PDF $f_{2,3}$ given by $f_{2,3}(y, z) = 6y$ for $0 \leq y \leq z \leq 1$
3.
 - X has PDF f_1 given by $f_1(x) = 3(1-x)^2$ for $0 \leq x \leq 1$
 - Y has PDF f_2 given by $f_2(y) = 6y(1-y)$ for $0 \leq y \leq 1$
 - Z has PDF f_3 given by $f_3(z) = 3z^2$ for $0 \leq z \leq 1$
4. Each pair of variables is dependent.

The Rejection Method

The following result shows how an arbitrary continuous distribution can be obtained from a uniform distribution. This result is useful for *simulating* certain continuous distributions, as we will see. To set up the basic notation, suppose that g is a probability density function for a continuous distribution on $S \subseteq \mathbb{R}^n$. Let

$$R = \{(x, y) : x \in S \text{ and } 0 \leq y \leq g(x)\} \subseteq \mathbb{R}^{n+1} \quad (3.4.27)$$

If (X, Y) is uniformly distributed on R , then X has probability density function g .

Proof

Note that since g is a probability density function on S .

$$\lambda_{n+1}(R) = \int_R 1 \, d(x, y) = \int_S \int_0^{g(x)} 1 \, dy \, dx = \int_S g(x) \, dx = 1 \quad (3.4.28)$$

Hence the probability density function f of (X, Y) is given by $f(x, y) = 1$ for $(x, y) \in R$. Thus, the probability density function of X is $x \mapsto \int_0^{g(x)} 1 \, dy = g(x)$ for $x \in S$.

A picture in the case $n = 1$ is given below:

Figure 3.4.2: If (X, Y) is uniformly distributed on R , then X has density function g .

The next result gives the *rejection method* for simulating a random variable with the probability density function g .

Suppose now that $R \subseteq T$ where $T \subseteq \mathbb{R}_{n+1}$ with $\lambda_{n+1}(T) < \infty$ and that $((X_1, Y_1), (X_2, Y_2), \dots)$ is a sequence of independent random variables with $X_k \in \mathbb{R}^n$, $Y_k \in \mathbb{R}$, and (X_k, Y_k) uniformly distributed on T for each $k \in \mathbb{N}_+$. Let

$$N = \min \{k \in \mathbb{N}_+ : (X_k, Y_k) \in R\} = \min \{k \in \mathbb{N}_+ : X_k \in S, 0 \leq Y_k \leq g(X_k)\} \quad (3.4.29)$$

1. N has the geometric distribution on \mathbb{N}_+ with success parameter $p = 1/\lambda_{n+1}(T)$.
2. (X_N, Y_N) is uniformly distributed on R .
3. X_N has probability density function g .

Proof

Figure 3.4.3: With a sequence of independent points, uniformly distributed on T , the x coordinate of the first point to land in R has probability density function g .

The point of the theorem is that if we can simulate a sequence of independent variables that are uniformly distributed on T , then we can simulate a random variable with the given probability density function g . Suppose in particular that R is bounded as a subset of \mathbb{R}^{n+1} , which would mean that the domain S is bounded as a subset of \mathbb{R}^n and that the probability density function g is bounded on S . In this case, we can find T that is the Cartesian product of $n + 1$ bounded intervals with $R \subseteq T$. It turns out to be very easy to simulate a sequence of independent variables, each uniformly distributed on such a product set, so the rejection method always works in this case. As you might guess, the rejection method works best if the size of T , namely $\lambda_{n+1}(T)$, is small, so that the success parameter p is large.

The rejection method app simulates a number of continuous distributions via the rejection method. For each of the following distributions, vary the parameters and note the shape and location of the probability density function. Then run the experiment 1000 times and observe the results.

1. The beta distribution
2. The semicircle distribution
3. The triangle distribution
4. The U-power distribution

The Multivariate Hypergeometric Distribution

Suppose that a population consists of m objects, and that each object is one of four types. There are a type 1 objects, b type 2 objects, c type 3 objects and $m - a - b - c$ type 0 objects. We sample n objects from the population at random, and without replacement. The parameters m , a , b , c , and n are nonnegative integers with $a + b + c \leq m$ and $n \leq m$. Denote the number of type 1, 2, and 3 objects in the sample by X , Y , and Z ,

respectively. Hence, the number of type 0 objects in the sample is $n - X - Y - Z$. In the problems below, the variables x , y , and z take values in \mathbb{N} .

(X, Y, Z) has a (multivariate) hypergeometric distribution with probability density function f given by

$$f(x, y, z) = \frac{\binom{a}{x} \binom{b}{y} \binom{c}{z} \binom{m-a-b-c}{n-x-y-z}}{\binom{m}{n}}, \quad x + y + z \leq n \quad (3.4.30)$$

Proof

From the basic theory of combinatorics, the numerator is the number of ways to select an unordered sample of size n from the population with x objects of type 1, y objects of type 2, z objects of type 3, and $n - x - y - z$ objects of type 0. The denominator is the total number of ways to select the unordered sample.

(X, Y) also has a (multivariate) hypergeometric distribution, with the probability density function g given by

$$g(x, y) = \frac{\binom{a}{x} \binom{b}{y} \binom{m-a-b}{n-x-y}}{\binom{m}{n}}, \quad x + y \leq n \quad (3.4.31)$$

Proof

This result could be obtained by summing the [joint PDF](#) over z for fixed (x, y) . However, there is a much nicer combinatorial argument. Note that we are selecting a random sample of size n from a population of m objects, with a objects of type 1, b objects of type 2, and $m - a - b$ objects of other types.

X has an ordinary hypergeometric distribution, with probability density function h given by

$$h(x) = \frac{\binom{a}{x} \binom{m-a}{n-x}}{\binom{m}{n}}, \quad x \leq n \quad (3.4.32)$$

Proof

Again, the result could be obtained by summing the [joint PDF](#) for (X, Y, Z) over (y, z) for fixed x , or by summing the [joint PDF](#) for (X, Y) over y for fixed x . But as before, there is a much more elegant combinatorial argument. Note that we are selecting a random sample of size n from a population of size m objects, with a objects of type 1 and $m - a$ objects of other types.

These results generalize in a straightforward way to a population with any number of types. In brief, if a random vector has a hypergeometric distribution, then any sub-vector also has a hypergeometric distribution. In other words, all of the marginal distributions of a hypergeometric distribution are themselves hypergeometric. Note however, that it's not a good idea to memorize the formulas above explicitly. It's better to just note the patterns and recall the combinatorial meaning of the binomial coefficient. The hypergeometric distribution and the multivariate hypergeometric distribution are studied in more detail in the chapter on Finite Sampling Models.

Suppose that a population of voters consists of 50 democrats, 40 republicans, and 30 independents. A sample of 10 voters is chosen at random from the population (without replacement, of course). Let X denote the number of democrats in the sample and Y the number of republicans in the sample. Find the probability density function of each of the following:

1. (X, Y)
2. X
3. Y

Answer

In the formulas for the PDFs below, the variables x and y are nonnegative integers.

1. (X, Y) has PDF f given by $f(x, y) = \frac{1}{\binom{120}{10}} \binom{50}{x} \binom{40}{y} \binom{30}{10-x-y}$ for $x + y \leq 10$
2. X has PDF g given by $g(x) = \frac{1}{\binom{120}{10}} \binom{50}{x} \binom{70}{10-x}$ for $x \leq 10$
3. Y has PDF h given by $h(y) = \frac{1}{\binom{120}{10}} \binom{40}{y} \binom{80}{10-y}$ for $y \leq 10$

Suppose that the Math Club at Enormous State University (ESU) has 50 freshmen, 40 sophomores, 30 juniors and 20 seniors. A sample of 10 club members is chosen at random to serve on the π -day committee. Let X denote the number freshmen on the committee, Y the number of sophomores, and Z the number of juniors.

1. Find the probability density function of (X, Y, Z)
2. Find the probability density function of each pair of variables.

3. Find the probability density function of each individual variable.

Answer

In the formulas for the PDFs below, the variables x , y , and z are nonnegative integers.

1. (X, Y, Z) has PDF f given by $f(x, y, z) = \frac{1}{\binom{140}{10}} \binom{50}{x} \binom{40}{y} \binom{30}{z} \binom{20}{10-x-y-z}$ for $x + y + z \leq 10$.
2.
 - (X, Y) has PDF $f_{1,2}$ given by $f_{1,2}(x, y) = \frac{1}{\binom{140}{10}} \binom{50}{x} \binom{40}{y} \binom{50}{10-x-y}$ for $x + y \leq 10$.
 - (X, Z) has PDF $f_{1,3}$ given by $f_{1,3}(y, z) = \frac{1}{\binom{140}{10}} \binom{50}{x} \binom{30}{z} \binom{60}{10-x-z}$ for $x + z \leq 10$.
 - (Y, Z) has PDF $f_{2,3}$ given by $f_{2,3}(y, z) = \frac{1}{\binom{140}{10}} \binom{40}{y} \binom{30}{z} \binom{70}{10-y-z}$ for $y + z \leq 10$.
3.
 - X has PDF f_1 given by $f_1(x) = \frac{1}{\binom{120}{10}} \binom{50}{x} \binom{90}{10-x}$ for $x \leq 10$.
 - Y has PDF f_2 given by $f_2(y) = \frac{1}{\binom{120}{10}} \binom{40}{y} \binom{100}{10-y}$ for $y \leq 10$.
 - Z has PDF f_3 given by $f_3(z) = \frac{1}{\binom{120}{10}} \binom{30}{z} \binom{110}{10-z}$ for $z \leq 10$.

Multinomial Trials

Suppose that we have a sequence of n independent trials, each with 4 possible outcomes. On each trial, outcome 1 occurs with probability p , outcome 2 with probability q , outcome 3 with probability r , and outcome 0 occurs with probability $1 - p - q - r$. The parameters p , q , and r are nonnegative numbers with $p + q + r \leq 1$, and $n \in \mathbb{N}_+$. Denote the number of times that outcome 1, outcome 2, and outcome 3 occurred in the n trials by X , Y , and Z respectively. Of course, the number of times that outcome 0 occurs is $n - X - Y - Z$. In the problems below, the variables x , y , and z take values in \mathbb{N} .

(X, Y, Z) has a *multinomial distribution* with probability density function f given by

$$f(x, y, z) = \binom{n}{x, y, z} p^x q^y r^z (1 - p - q - r)^{n-x-y-z}, \quad x + y + z \leq n \quad (3.4.33)$$

Proof

The multinomial coefficient is the number of sequences of length n with 1 occurring x times, 2 occurring y times, 3 occurring z times, and 0 occurring $n - x - y - z$ times. The result then follows by independence.

(X, Y) also has a multinomial distribution with the probability density function g given by

$$g(x, y) = \binom{n}{x, y} p^x q^y (1 - p - q)^{n-x-y}, \quad x + y \leq n \quad (3.4.34)$$

Proof

This result could be obtained from the [joint PDF](#) above, by summing over z for fixed (x, y) . However there is a much better direct argument. Note that we have n independent trials, and on each trial, outcome 1 occurs with probability p , outcome 2 with probability q , and some other outcome with probability $1 - p - q$.

X has a *binomial distribution*, with the probability density function h given by

$$h(x) = \binom{n}{x} p^x (1 - p)^{n-x}, \quad x \leq n \quad (3.4.35)$$

Proof

Again, the result could be obtained by summing the [joint PDF](#) for (X, Y, Z) over (y, z) for fixed x or by summing the [joint PDF](#) for (X, Y) over y for fixed x . But as before, there is a much better direct argument. Note that we have n independent trials, and on each trial, outcome 1 occurs with probability p and some other outcome with probability $1 - p$.

These results generalize in a completely straightforward way to multinomial trials with any number of trial outcomes. In brief, if a random vector has a multinomial distribution, then any sub-vector also has a multinomial distribution. In other terms, all of the marginal distributions of a multinomial distribution are themselves multinomial. The binomial distribution and the multinomial distribution are studied in more detail in the chapter on Bernoulli Trials.

Suppose that a system consists of 10 components that operate independently. Each component is *working* with probability $\frac{1}{2}$, *idle* with probability $\frac{1}{3}$, or *failed* with probability $\frac{1}{6}$. Let X denote the number of working components and Y the number of idle components. Give the probability density function of each of the following:

1. (X, Y)
2. X
3. Y

Answer

In the formulas below, the variables x and y are nonnegative integers.

1. (X, Y) has PDF f given by $f(x, y) = \binom{10}{x, y} \left(\frac{1}{2}\right)^x \left(\frac{1}{3}\right)^y \left(\frac{1}{6}\right)^{10-x-y}$ for $x + y \leq 10$.
2. X has PDF g given by $g(x) = \binom{10}{x} \left(\frac{1}{2}\right)^{10}$ for $x \leq 10$.
3. Y has PDF h given by $h(y) = \binom{10}{y} \left(\frac{1}{3}\right)^y \left(\frac{2}{3}\right)^{10-y}$ for $y \leq 10$.

Suppose that in a crooked, four-sided die, face i occurs with probability $\frac{i}{10}$ for $i \in \{1, 2, 3, 4\}$. The die is thrown 12 times; let X denote the number of times that score 1 occurs, Y the number of times that score 2 occurs, and Z the number of times that score 3 occurs.

1. Find the probability density function of (X, Y, Z)
2. Find the probability density function of each pair of variables.
3. Find the probability density function of each individual variable.

Answer

In the formulas for the PDFs below, the variables x , y and z are nonnegative integers.

1. (X, Y, Z) has PDF f given by $f(x, y, z) = \binom{12}{x, y, z} \left(\frac{1}{10}\right)^x \left(\frac{2}{10}\right)^y \left(\frac{3}{10}\right)^z \left(\frac{4}{10}\right)^{12-x-y-z}$, $x + y + z \leq 12$
2. (X, Y) has PDF $f_{1,2}$ given by $f_{1,2}(x, y) = \binom{12}{x, y} \left(\frac{1}{10}\right)^x \left(\frac{2}{10}\right)^y \left(\frac{7}{10}\right)^{12-x-y}$ for $x + y \leq 12$.
 - (X, Z) has PDF $f_{1,3}$ given by $f_{1,3}(x, z) = \binom{12}{x, z} \left(\frac{1}{10}\right)^x \left(\frac{3}{10}\right)^z \left(\frac{6}{10}\right)^{12-x-z}$ for $x + z \leq 12$.
 - (Y, Z) has PDF $f_{2,3}$ given by $f_{2,3}(y, z) = \binom{12}{y, z} \left(\frac{2}{10}\right)^y \left(\frac{3}{10}\right)^z \left(\frac{5}{10}\right)^{12-y-z}$ for $y + z \leq 12$.
3. X has PDF f_1 given by $f_1(x) = \binom{12}{x} \left(\frac{1}{10}\right)^x \left(\frac{9}{10}\right)^{12-x}$ for $x \leq 12$.
 - Y has PDF f_2 given by $f_2(y) = \binom{12}{y} \left(\frac{2}{10}\right)^y \left(\frac{8}{10}\right)^{12-y}$ for $y \leq 12$.
 - Z has PDF f_3 given by $f_3(z) = \binom{12}{z} \left(\frac{3}{10}\right)^z \left(\frac{7}{10}\right)^{12-z}$ for $z \leq 12$.

Bivariate Normal Distributions

Suppose that (X, Y) has probability the density function f given below:

$$f(x, y) = \frac{1}{12\pi} \exp\left[-\left(\frac{x^2}{8} + \frac{y^2}{18}\right)\right], \quad (x, y) \in \mathbb{R}^2 \quad (3.4.36)$$

1. Find the probability density function of X .
2. Find the probability density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = \frac{1}{2\sqrt{2\pi}} e^{-x^2/8}$ for $x \in \mathbb{R}$.
2. Y has PDF h given by $h(y) = \frac{1}{3\sqrt{2\pi}} e^{-y^2/18}$ for $y \in \mathbb{R}$.
3. X and Y are independent.

Suppose that (X, Y) has probability density function f given below:

$$f(x, y) = \frac{1}{\sqrt{3}\pi} \exp\left[-\frac{2}{3}(x^2 - xy + y^2)\right], \quad (x, y) \in \mathbb{R}^2 \quad (3.4.37)$$

1. Find the density function of X .
2. Find the density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ for $x \in \mathbb{R}$.
2. Y has PDF h given by $h(y) = \frac{1}{\sqrt{2\pi}} e^{-y^2/2}$ for $y \in \mathbb{R}$.

3. X and Y are dependent.

The joint distributions in the last two exercises are examples of *bivariate normal distributions*. Normal distributions are widely used to model physical measurements subject to small, random errors. In both exercises, the marginal distributions of X and Y also have normal distributions, and this turns out to be true in general. The multivariate normal distribution is studied in more detail in the chapter on Special Distributions.

Exponential Distributions

Recall that the *exponential distribution* has probability density function

$$f(x) = re^{-rt}, \quad x \in [0, \infty) \quad (3.4.38)$$

where $r \in (0, \infty)$ is the *rate parameter*. The exponential distribution is widely used to model random times, and is studied in more detail in the chapter on the Poisson Process.

Suppose X and Y have exponential distributions with parameters $a \in (0, \infty)$ and $b \in (0, \infty)$, respectively, and are independent. Then $\mathbb{P}(X < Y) = \frac{a}{a+b}$.

Suppose X , Y , and Z have exponential distributions with parameters $a \in (0, \infty)$, $b \in (0, \infty)$, and $c \in (0, \infty)$, respectively, and are independent. Then

1. $\mathbb{P}(X < Y < Z) = \frac{a}{a+b+c} \frac{b}{b+c}$
2. $\mathbb{P}(X < Y, X < Z) = \frac{a}{a+b+c}$

If X , Y , and Z are the lifetimes of devices that act independently, then the results in the previous two exercises give probabilities of various failure orders. Results of this type are also very important in the study of continuous-time Markov processes. We will continue this discussion in the section on transformations of random variables.

Mixed Coordinates

Suppose X takes values in the finite set $\{1, 2, 3\}$, Y takes values in the interval $[0, 3]$, and that (X, Y) has probability density function f given by

$$f(x, y) = \begin{cases} \frac{1}{3}, & x = 1, 0 \leq y \leq 1 \\ \frac{1}{6}, & x = 2, 0 \leq y \leq 2 \\ \frac{1}{9}, & x = 3, 0 \leq y \leq 3 \end{cases} \quad (3.4.39)$$

1. Find the probability density function of X .
2. Find the probability density function of Y .
3. Are X and Y independent?

Answer

1. X has PDF g given by $g(x) = \frac{1}{3}$ for $x \in \{1, 2, 3\}$ (the uniform distribution on $\{1, 2, 3\}$).
2. Y has PDF h given by $h(y) = \begin{cases} \frac{11}{18}, & 0 < y < 1 \\ \frac{5}{18}, & 1 < y < 2 \\ \frac{2}{18}, & 2 < y < 3 \end{cases}$.
3. X and Y are dependent.

Suppose that P takes values in the interval $[0, 1]$, X takes values in the finite set $\{0, 1, 2, 3\}$ and that (P, X) has probability density function f given by

$$f(p, x) = 6 \binom{3}{x} p^{x+1} (1-p)^{4-x}, \quad (p, x) \in [0, 1] \times \{0, 1, 2, 3\} \quad (3.4.40)$$

1. Find the probability density function of P .
2. Find the probability density function of X .
3. Are P and X independent?

Answer

1. P has PDF g given by $g(p) = 6p(1-p)$ for $0 \leq p \leq 1$.
2. X has PDF h given by $h(0) = h(3) = \frac{1}{5}$, $h(1) = \frac{3}{10}$.
3. P and X are dependent.

As we will see in the section on conditional distributions, the distribution in the last exercise models the following experiment: a random probability P is selected, and then a coin with this probability of heads is tossed 3 times; X is the number of heads. Note that P has a beta distribution.

Random Samples

Recall that the *Bernoulli distribution* with parameter $p \in [0, 1]$ has probability density function g given by $g(x) = p^x(1-p)^{1-x}$ for $x \in \{0, 1\}$. Let $\mathbf{X} = (X_1, X_2, \dots, X_n)$ be a random sample of size $n \in \mathbb{N}_+$ from the distribution. Give the probability density function of \mathbf{X} in simplified form.

Answer

\mathbf{X} has PDF f given by $f(x_1, x_2, \dots, x_n) = p^y(1-p)^{n-y}$ for $(x_1, x_2, \dots, x_n) \in \{0, 1\}^n$, where $y = x_1 + x_2 + \dots + x_n$.

The Bernoulli distribution is named for Jacob Bernoulli, and governs an indicator random variable. Hence if \mathbf{X} is a random sample of size n from the distribution then \mathbf{X} is a sequence of n *Bernoulli trials*. A separate chapter studies Bernoulli trials in more detail.

Recall that the *geometric distribution* on \mathbb{N}_+ with parameter $p \in (0, 1)$ has probability density function g given by $g(x) = p(1-p)^{x-1}$ for $x \in \mathbb{N}_+$. Let $\mathbf{X} = (X_1, X_2, \dots, X_n)$ be a random sample of size $n \in \mathbb{N}_+$ from the distribution. Give the probability density function of \mathbf{X} in simplified form.

Answer

\mathbf{X} has pdf f given by $f(x_1, x_2, \dots, x_n) = p^n(1-p)^{y-n}$ for $(x_1, x_2, \dots, x_n) \in \mathbb{N}_+^n$, where $y = x_1 + x_2 + \dots + x_n$.

The geometric distribution governs the trial number of the first success in a sequence of Bernoulli trials. Hence the variables in the random sample can be interpreted as the number of trials between successive successes.

Recall that the *Poisson distribution* with parameter $a \in (0, \infty)$ has probability density function g given by $g(x) = e^{-a} \frac{a^x}{x!}$ for $x \in \mathbb{N}$. Let $\mathbf{X} = (X_1, X_2, \dots, X_n)$ be a random sample of size $n \in \mathbb{N}_+$ from the distribution. Give the probability density function of \mathbf{X} in simplified form.

Answer

\mathbf{X} has PDF f given by $f(x_1, x_2, \dots, x_n) = \frac{1}{x_1!x_2!\dots x_n!} e^{-na} a^y$ for $(x_1, x_2, \dots, x_n) \in \mathbb{N}^n$, where $y = x_1 + x_2 + \dots + x_n$.

The Poisson distribution is named for Simeon Poisson, and governs the number of random points in a region of time or space under appropriate circumstances. The parameter a is proportional to the size of the region. The Poisson distribution is studied in more detail in the chapter on the Poisson process.

Recall again that the *exponential distribution* with rate parameter $r \in (0, \infty)$ has probability density function g given by $g(x) = re^{-rx}$ for $x \in (0, \infty)$. Let $\mathbf{X} = (X_1, X_2, \dots, X_n)$ be a random sample of size $n \in \mathbb{N}_+$ from the distribution. Give the probability density function of \mathbf{X} in simplified form.

Answer

\mathbf{X} has PDF f given by $f(x_1, x_2, \dots, x_n) = r^n e^{-ry}$ for $(x_1, x_2, \dots, x_n) \in [0, \infty)^n$, where $y = x_1 + x_2 + \dots + x_n$.

The exponential distribution governs failure times and other types of arrival times under appropriate circumstances. The exponential distribution is studied in more detail in the chapter on the Poisson process. The variables in the random sample can be interpreted as the times between successive arrivals in the Poisson process.

Recall that the *standard normal distribution* has probability density function ϕ given by $\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}$ for $z \in \mathbb{R}$. Let $\mathbf{Z} = (Z_1, Z_2, \dots, Z_n)$ be a random sample of size $n \in \mathbb{N}_+$ from the distribution. Give the probability density function of \mathbf{Z} in simplified form.

Answer

\mathbf{Z} has PDF f given by $f(z_1, z_2, \dots, z_n) = \frac{1}{(2\pi)^{n/2}} e^{-\frac{1}{2}w^2}$ for $(z_1, z_2, \dots, z_n) \in \mathbb{R}^n$, where $w^2 = z_1^2 + z_2^2 + \dots + z_n^2$.

The standard normal distribution governs physical quantities, properly scaled and centered, subject to small, random errors. The normal distribution is studied in more generality in the chapter on the Special Distributions.

Data Analysis Exercises

For the cicada data, G denotes gender and S denotes species type.

1. Find the empirical density of (G, S) .
2. Find the empirical density of G .
3. Find the empirical density of S .

4. Do you believe that S and G are independent?

Answer

The empirical joint and marginal empirical densities are given in the table below. Gender and species are probably dependent (compare the joint density with the product of the marginal densities).

$f(i, j)$	$i = 0$	1	$h(j)$
$j = 0$	$\frac{16}{104}$	$\frac{28}{104}$	$\frac{44}{104}$
1	$\frac{3}{104}$	$\frac{3}{104}$	$\frac{6}{104}$
2	$\frac{40}{104}$	$\frac{14}{104}$	$\frac{56}{104}$
$g(i)$	$\frac{59}{104}$	$\frac{45}{104}$	1

For the cicada data, let W denote body weight (in grams) and L body length (in millimeters).

1. Construct an empirical density for (W, L) .
2. Find the corresponding empirical density for W .
3. Find the corresponding empirical density for L .
4. Do you believe that W and L are independent?

Answer

The empirical joint and marginal densities, based on simple partitions of the body weight and body length ranges, are given in the table below. Body weight and body length are almost certainly dependent.

Density (W, L)	$w \in (0, 0.1]$	$(0.1, 0.2]$	$(0.2, 0.3]$	$(0.3, 0.4]$	Density L
$l \in (15, 20]$	0	0.0385	0.0192	0	0.0058
$(20, 25]$	0.1731	0.9808	0.4231	0	0.1577
$(25, 30]$	0	0.1538	0.1731	0.0192	0.0346
$(30, 35]$	0	0	0	0.0192	0.0019
Density W	0.8654	5.8654	3.0769	0.1923	

For the cicada data, let G denote gender and W body weight (in grams).

1. Construct an empirical density for (W, G) .
2. Find the empirical density for G .
3. Find the empirical density for W .
4. Do you believe that G and W are independent?

Answer

The empirical joint and marginal densities, based on a simple partition of the body weight range, are given in the table below. Body weight and gender are almost certainly dependent.

Density (W, G)	$w \in (0, 0.1]$	$(0.1, 0.2]$	$(0.2, 0.3]$	$(0.3, 0.4]$	Density G
$g = 0$	0.1923	2.5000	2.8846	0.0962	0.5673
1	0.6731	3.3654	0.1923	0.0962	0.4327
Density W	0.8654	5.8654	3.0769	0.1923	

3.5: Conditional Distributions

In this section, we study how a probability distribution changes when a given random variable has a known, specified value. So this is an essential topic that deals with how probability measures should be updated in light of new information. As usual, if you are a new student or probability, you may want to skip the technical details.

Basic Theory

Our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} is the collection of events, and \mathbb{P} is the probability measure on the underlying sample space (Ω, \mathcal{F}) .

Suppose that X is a random variable defined on the sample space (that is, defined for the experiment), taking values in a set S .

Details

Technically, the collection of events \mathcal{F} is a σ -algebra, so that the sample space (Ω, \mathcal{F}) is a measurable space. Similarly, S will have a σ -algebra of admissible subsets, so that (S, \mathcal{S}) is also a measurable space. Random variable X is measurable, so that $\{X \in A\} \in \mathcal{F}$ for every $A \in \mathcal{S}$. The *distribution* of X is the probability measure $A \mapsto \mathbb{P}(X \in A)$ for $A \in \mathcal{S}$.

The purpose of this section is to study the conditional probability measure given $X = x$ for $x \in S$. That is, if E is an event, we would like to define and study the probability of E given $X = x$, denoted $\mathbb{P}(E | X = x)$. If X has a discrete distribution, the conditioning event has positive probability, so no new concepts are involved, and the simple definition of conditional probability suffices. When X has a continuous distribution, however, the conditioning event has probability 0, so a fundamentally new approach is needed.

The Discrete Case

Suppose first that X has a discrete distribution with probability density function g . Thus S is countable and we can assume that $g(x) = \mathbb{P}(X = x) > 0$ for $x \in S$.

If E is an event and $x \in S$ then

$$\mathbb{P}(E | X = x) = \frac{\mathbb{P}(E, X = x)}{g(x)} \quad (3.5.1)$$

Proof

The meaning of *discrete distribution* is that S is countable and $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S . Technically, g is the probability density function of X with respect to counting measure $\#$ on S , the standard measure for discrete spaces. In the displayed equation above, the comma separating the events in the numerator of the fraction means *and*, and thus functions just like the intersection symbol. This result follows immediately from the definition of conditional probability:

$$\mathbb{P}(E | X = x) = \frac{\mathbb{P}(E, X = x)}{\mathbb{P}(X = x)} = \frac{\mathbb{P}(E, X = x)}{g(x)} \quad (3.5.2)$$

The next result is a special case of the law of total probability, and will be the key to the definition when X has a continuous distribution.

If E is an event then

$$\mathbb{P}(E, X \in A) = \sum_{x \in A} g(x) \mathbb{P}(E | X = x), \quad A \subseteq S \quad (3.5.3)$$

Conversely, this condition uniquely determines $\mathbb{P}(E | X = x)$.

Proof

As noted, the displayed equation is just a special case of the law of total probability. For $A \subseteq S$, the countable collection of events $\{\{X = x\} : x \in A\}$ partitions $\{X \in A\}$ so

$$\mathbb{P}(E, X \in A) = \sum_{x \in A} \mathbb{P}(E, X = x) = \sum_{x \in A} \mathbb{P}(E | X = x) \mathbb{P}(X = x) = \sum_{x \in A} \mathbb{P}(E | X = x) g(x) \quad (3.5.4)$$

Conversely, suppose that the function $Q(x, E)$, defined for $x \in S$ and $E \in \mathcal{F}$, satisfies

$$\mathbb{P}(E, X \in A) = \sum_{x \in A} g(x) Q(x, E), \quad A \subseteq S \quad (3.5.5)$$

Letting $A = \{x\}$ for $x \in S$ gives $\mathbb{P}(E, X = x) = g(x)Q(x, E)$, so $Q(x, E) = \mathbb{P}(E, X = x)/g(x) = \mathbb{P}(E | X = x)$.

The Continuous Case

Suppose now that X has a continuous distribution on $S \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$, with probability density function g . We assume that $g(x) > 0$ for $x \in S$. Unlike the discrete case, we cannot use simple conditional probability to define $\mathbb{P}(E | X = x)$ for an event E and $x \in S$ because the conditioning event has probability 0. Nonetheless, the concept *should* make sense. If we actually run the experiment, X will take on some value x (even though *a priori*, this event occurs with probability 0), and surely the information that $X = x$ should in general alter the probabilities that we assign to other events. A natural approach is to use the results obtained in the discrete case as *definitions* in the continuous case.

If E is an event and $x \in S$, the *conditional probability* $\mathbb{P}(E | X = x)$ is defined by the requirement that

$$\mathbb{P}(E, X \in A) = \int_A g(x)\mathbb{P}(E | X = x) dx, \quad A \subseteq S \quad (3.5.6)$$

Details

Technically, S is a measurable subset of \mathbb{R}^n and the σ -algebra \mathcal{S} consists of the subsets of S that are also measurable as subsets of \mathbb{R}^n . The function g is also required to be measurable, and is the density function of X with respect to Lebesgue measure λ_n . Lebesgue measure is named for Henri Lebesgue and is the standard measure on \mathbb{R}^n .

We will accept the fact that $\mathbb{P}(E | X = x)$ can be defined uniquely, up to a set of measure 0, by the condition above, but we will return to this point in the section on Conditional Expectation in the chapter on Expected Value. Essentially the condition means that $\mathbb{P}(E | X = x)$ is defined so that $x \mapsto g(x)\mathbb{P}(E | X = x)$ is a density function for the finite measure $A \mapsto \mathbb{P}(E, X \in A)$.

Conditioning and Bayes' Theorem

Suppose again that X is a random variable with values in S and probability density function g , as described above. Our discussions above in the discrete and continuous cases lead to basic formulas for computing the probability of an event by *conditioning on X* .

The law of total probability. If E is an event, then $\mathbb{P}(E)$ can be computed as follows:

1. If X has a discrete distribution then

$$\mathbb{P}(E) = \sum_{x \in S} g(x)\mathbb{P}(E | X = x) \quad (3.5.7)$$

2. If X has a continuous distribution then

$$\mathbb{P}(E) = \int_S g(x)\mathbb{P}(E | X = x) dx \quad (3.5.8)$$

Proof

1. This follows from the [discrete theorem](#) with $A = S$.
2. This follows from the [fundamental definition](#) with $A = S$.

Naturally, the law of total probability is useful when $\mathbb{P}(E | X = x)$ and $g(x)$ are known for $x \in S$. Our next result is, *Bayes' Theorem*, named after Thomas Bayes.

Bayes' Theorem. Suppose that E is an event with $\mathbb{P}(E) > 0$. The conditional probability density function $x \mapsto g(x | E)$ of X given E can be computed as follows:

1. If X has a discrete distribution then

$$g(x | E) = \frac{g(x)\mathbb{P}(E | X = x)}{\sum_{s \in S} g(s)\mathbb{P}(E | X = s)}, \quad x \in S \quad (3.5.9)$$

2. If X has a continuous distribution then

$$g(x | E) = \frac{g(x)\mathbb{P}(E | X = x)}{\int_S g(s)\mathbb{P}(E | X = s) ds}, \quad x \in S \quad (3.5.10)$$

Proof

1. In the discrete case, as usual, the ordinary simple definition of conditional probability suffices. The numerator in the displayed equation is $\mathbb{P}(X = x)\mathbb{P}(E | X = x) = \mathbb{P}(E, X = x)$. The denominator is $\mathbb{P}(E)$ by part (a) of the [law of total probability](#). Hence the fraction is $\mathbb{P}(E, X = x)/\mathbb{P}(E) = \mathbb{P}(X = x | E)$.
2. In the continuous case, as usual, the argument is more subtle. We need to show that the expression in the displayed equation satisfies the defining property of a PDF for the conditional distribution. Once again, the denominator is $\mathbb{P}(E)$ by part (b) of the [law of total probability](#). If $A \subseteq S$ then using the [fundamental definition](#),

$$\int_A g(x | E) dx = \frac{1}{\mathbb{P}(E)} \int_A g(x)\mathbb{P}(E | X = x) dx = \frac{\mathbb{P}(E, X \in A)}{\mathbb{P}(E)} = \mathbb{P}(X \in A | E) \quad (3.5.11)$$

By the meaning of the term, $x \mapsto g(x | E)$ is the conditional probability density function of X given E .

In the context of Bayes' theorem, g is called the *prior probability density function* of X and $x \mapsto g(x | E)$ is the *posterior probability density function* of X given E . Note also that the conditional probability density function of X given E is proportional to the function $x \mapsto g(x)\mathbb{P}(E | X = x)$, the sum or integral of this function that occurs in the denominator is simply the normalizing constant. As with the law of total probability, Bayes' theorem is useful when $\mathbb{P}(E | X = x)$ and $g(x)$ are known for $x \in S$.

Conditional Probability Density Functions

The definitions and results above apply, of course, if E is an event defined in terms of another random variable for our experiment. Here is the setup:

Suppose that X and Y are random variables on the probability space, with values in sets S and T , respectively, so that (X, Y) is a random variable with values in $S \times T$. We assume that (X, Y) has probability density function f , as discussed in the section on Joint Distributions. Recall that X has probability density function g defined as follows:

1. If Y has a discrete distribution on the countable set T then

$$g(x) = \sum_{y \in T} f(x, y), \quad x \in S \quad (3.5.12)$$

2. If Y has a continuous distribution on $T \subseteq \mathbb{R}^k$ then

$$g(x) = \int_T f(x, y) dy, \quad x \in S \quad (3.5.13)$$

Similarly, the probability density function h of Y can be obtained by summing f over $x \in S$ if X has a discrete distribution or integrating f over S if X has a continuous distribution.

Suppose that $x \in S$ and that $g(x) > 0$. The function $y \mapsto h(y | x)$ defined below is a probability density function on T :

$$h(y | x) = \frac{f(x, y)}{g(x)}, \quad y \in T \quad (3.5.14)$$

Proof

The result is simple, since $g(x)$ is the normalizing constant for $y \mapsto h(y | x)$. Specifically, fix $x \in S$. Then $h(y | x) \geq 0$. If Y has a discrete distribution then

$$\sum_{y \in T} h(y | x) = \frac{1}{g(x)} \sum_{y \in T} f(x, y) = \frac{g(x)}{g(x)} = 1 \quad (3.5.15)$$

Similarly, if Y has a continuous distribution then

$$\int_T h(y | x) dy = \frac{1}{g(x)} \int_T f(x, y) dy = \frac{g(x)}{g(x)} = 1 \quad (3.5.16)$$

The distribution that corresponds to this probability density function is what you would expect:

For $x \in S$, the function $y \mapsto h(y | x)$ is the conditional probability density function of Y given $X = x$. That is,

1. If Y has a discrete distribution then

$$\mathbb{P}(Y \in B \mid X = x) = \sum_{y \in B} h(y \mid x), \quad B \subseteq T \quad (3.5.17)$$

2. If Y has a continuous distribution then

$$\mathbb{P}(Y \in B \mid X = x) = \int_B h(y \mid x) dy, \quad B \subseteq T \quad (3.5.18)$$

Proof

There are four cases, depending on the type of distribution of X and Y , but the computations are identical, except for sums in the discrete case and integrals in the continuous case. The main tool is the [basic theorem](#) when X has a discrete distribution and the [fundamental definition](#) when X has a continuous distribution, with the event E replaced by $\{Y \in B\}$ for $B \subseteq T$. The other main element is the fact that f is the PDF of the (joint) distribution of (X, Y) .

1. Suppose that Y has a discrete distribution on the countable set T . If X also has a discrete distribution on the countable set S then

$$\sum_{x \in A} g(x) \sum_{y \in B} h(y \mid x) = \sum_{x \in A} \sum_{y \in B} g(x) h(y \mid x) = \sum_{x \in A} \sum_{y \in B} f(x, y) = \mathbb{P}(X \in A, Y \in B), \quad A \subseteq S \quad (3.5.19)$$

In this jointly discrete case, there is a simpler argument of course:

$$h(y \mid x) = \frac{f(x, y)}{g(x)} = \frac{\mathbb{P}(X = x, Y = y)}{P(X = x)} = \mathbb{P}(Y = y \mid X = x), \quad y \in T \quad (3.5.20)$$

If X has a continuous distribution on $S \subseteq \mathbb{R}^j$ then

$$\int_A g(x) \sum_{y \in B} h(y \mid x) dx = \int_A \sum_{y \in B} g(x) h(y \mid x) dx = \int_A \sum_{y \in B} f(x, y) dx = \mathbb{P}(X \in A, Y \in B), \quad A \subseteq S \quad (3.5.21)$$

2. Suppose that Y has continuous distributions on $T \subseteq \mathbb{R}^k$. If X has a discrete distribution on the countable set S then

$$\sum_{x \in A} g(x) \int_B h(y \mid x) dy = \sum_{x \in A} \int_B g(x) h(y \mid x) dy = \sum_{x \in A} \int_B f(x, y) dy = \mathbb{P}(X \in A, Y \in B), \quad A \subseteq S \quad (3.5.22)$$

If X has a continuous distribution $S \subseteq \mathbb{R}^j$ then

$$\int_A g(x) \int_B h(y \mid x) dy dx = \int_A \int_B g(x) h(y \mid x) dy dx = \int_A \int_B f(x, y) dy dx = \mathbb{P}(X \in A, Y \in B), \quad A \subseteq S \quad (3.5.23)$$

The following theorem gives Bayes' theorem for probability density functions. We use the notation established above.

Bayes' Theorem. For $y \in T$, the conditional probability density function $x \mapsto g(x \mid y)$ of X given $y = y$ can be computed as follows:

1. If X has a discrete distribution then

$$g(x \mid y) = \frac{g(x)h(y \mid x)}{\sum_{s \in S} g(s)h(y \mid s)}, \quad x \in S \quad (3.5.24)$$

2. If X has a continuous distribution then

$$g(x \mid y) = \frac{g(x)h(y \mid x)}{\int_S g(s)h(y \mid s)ds}, \quad x \in S \quad (3.5.25)$$

Proof

In both cases the numerator is $f(x, y)$ while the denominator is $h(y)$.

In the context of Bayes' theorem, g is the *prior probability density function* of X and $x \mapsto g(x \mid y)$ is the *posterior probability density function* of X given $Y = y$ for $y \in T$. Note that the posterior probability density function $x \mapsto g(x \mid y)$ is proportional to the function $x \mapsto g(x)h(y \mid x)$. The sum or integral in the denominator is the normalizing constant.

Independence

Intuitively, X and Y should be independent if and only if the conditional distributions are the same as the corresponding unconditional distributions.

The following conditions are equivalent:

1. X and Y are independent.
2. $f(x, y) = g(x)h(y)$ for $x \in S, y \in T$
3. $h(y | x) = h(y)$ for $x \in S, y \in T$
4. $g(x | y) = g(x)$ for $x \in S, y \in T$

Proof

The equivalence of (a) and (b) was established in the section on joint distributions. Parts (c) and (d) are equivalent to (b). For a continuous distribution as described in the details in (4), a probability density function is not unique. The values of a PDF can be changed to other nonnegative values on a set of measure 0 and the resulting function is still a PDF. So if X or Y has a continuous distribution, the equations above have to be interpreted as holding for x or y , respectively, except on a set of measure 0.

Examples and Applications

In the exercises that follow, look for special models and distributions that we have studied. A special distribution may be embedded in a larger problem, as a conditional distribution, for example. In particular, a conditional distribution sometimes arises when a parameter of a standard distribution is *randomized*.

A couple of special distributions will occur frequently in the exercises. First, recall that the discrete uniform distribution on a finite, nonempty set S has probability density function f given by $f(x) = 1/\#(S)$ for $x \in S$. This distribution governs an element selected at random from S .

Recall also that *Bernoulli trials* (named for Jacob Bernoulli) are independent trials, each with two possible outcomes generically called *success* and *failure*. The probability of success $p \in [0, 1]$ is the same for each trial, and is the basic parameter of the random process. The number of successes in $n \in \mathbb{N}_+$ Bernoulli trials has the *binomial distribution* with parameters n and p . This distribution has probability density function f given by $f(x) = \binom{n}{x} p^x (1-p)^{n-x}$ for $x \in \{0, 1, \dots, n\}$. The binomial distribution is studied in more detail in the chapter on Bernoulli trials

Coins and Dice

Suppose that two standard, fair dice are rolled and the sequence of scores (X_1, X_2) is recorded. Let $U = \min\{X_1, X_2\}$ and $V = \max\{X_1, X_2\}$ denote the minimum and maximum scores, respectively.

1. Find the conditional probability density function of U given $V = v$ for each $v \in \{1, 2, 3, 4, 5, 6\}$.
2. Find the conditional probability density function of V given $U = u$ for each $u \in \{1, 2, 3, 4, 5, 6\}$

Answer

1.	$g(u v)$	$u = 1$	2	3	4	5	6
	$v = 1$	1	0	0	0	0	0
	2	$\frac{2}{3}$	$\frac{1}{3}$	0	0	0	0
	3	$\frac{2}{5}$	$\frac{2}{5}$	$\frac{1}{5}$	0	0	0
	4	$\frac{2}{7}$	$\frac{2}{7}$	$\frac{2}{7}$	$\frac{1}{7}$	0	0
	5	$\frac{2}{9}$	$\frac{2}{9}$	$\frac{2}{9}$	$\frac{2}{9}$	$\frac{1}{9}$	0
	6	$\frac{2}{11}$	$\frac{2}{11}$	$\frac{2}{11}$	$\frac{2}{11}$	$\frac{2}{11}$	$\frac{1}{11}$

2.	$h(v u)$	$u = 1$	2	3	4	5	6
	$v = 1$	$\frac{1}{11}$	0	0	0	0	0
	2	$\frac{2}{11}$	$\frac{1}{9}$	0	0	0	0
	3	$\frac{2}{11}$	$\frac{2}{9}$	$\frac{1}{7}$	0	0	0
	4	$\frac{2}{11}$	$\frac{2}{9}$	$\frac{2}{7}$	$\frac{1}{5}$	0	0
	5	$\frac{2}{11}$	$\frac{2}{9}$	$\frac{2}{7}$	$\frac{2}{5}$	$\frac{1}{3}$	0

$h(v u)$	$u = 1$	2	3	4	5	6
6	$\frac{2}{11}$	$\frac{2}{9}$	$\frac{2}{7}$	$\frac{2}{5}$	$\frac{2}{3}$	1

In the die-coin experiment, a standard, fair die is rolled and then a fair coin is tossed the number of times showing on the die. Let N denote the die score and Y the number of heads.

- Find the joint probability density function of (N, Y) .
- Find the probability density function of Y .
- Find the conditional probability density function of N given $Y = y$ for each $y \in \{0, 1, 2, 3, 4, 5, 6\}$

Answer

- and b.

$f(n, y)$	$n = 1$	2	3	4	5	6	$h(y)$

In the die-coin experiment, select the fair die and coin.

- Run the simulation of 1000 times and compare the empirical density function of Y with the true probability density function in the previous exercise
- Run the simulation 1000 times and compute the empirical conditional density function of N given $Y = 3$. Compare with the conditional probability density functions in the previous exercise.

In the coin-die experiment, a fair coin is tossed. If the coin is tails, a standard, fair die is rolled. If the coin is heads, a standard, ace-six flat die is rolled (faces 1 and 6 have probability $\frac{1}{4}$ each and faces 2, 3, 4, 5 have probability $\frac{1}{8}$ each). Let X denote the coin score (0 for tails and 1 for heads) and Y the die score.

- Find the joint probability density function of (X, Y) .
- Find the probability density function of Y .
- Find the conditional probability density function of X given $Y = y$ for each $y \in \{1, 2, 3, 4, 5, 6\}$

Answer

1. and b.

$f(x, y)$	$y = 1$	2	3	4	5	6	$g(x)$
$x = 0$	$\frac{1}{12}$	$\frac{1}{12}$	$\frac{1}{12}$	$\frac{1}{12}$	$\frac{1}{12}$	$\frac{1}{12}$	$\frac{1}{2}$

In the coin-die experiment, select the settings of the previous exercise.

1. Run the simulation 1000 times and compare the empirical density function of Y with the true probability density function in the previous exercise.
2. Run the simulation 100 times and compute the empirical conditional probability density function of X given $Y = 2$. Compare with the conditional probability density function in the previous exercise.

Suppose that a box contains 12 coins: 5 are fair, 4 are biased so that heads comes up with probability $\frac{1}{3}$, and 3 are two-headed. A coin is chosen at random and tossed 2 times. Let P denote the probability of heads of the selected coin, and X the number of heads.

1. Find the joint probability density function of (P, X) .
2. Find the probability density function of X .
3. Find the conditional probability density function of P given $X = x$ for $x \in \{0, 1, 2\}$.

Answer

1. and b.

$f(p, x)$	$x = 0$	1	2	$g(p)$
$p = \frac{1}{2}$	$\frac{5}{48}$	$\frac{10}{48}$	$\frac{5}{48}$	$\frac{5}{12}$
$\frac{1}{3}$	$\frac{4}{27}$	$\frac{4}{27}$	$\frac{1}{27}$	$\frac{4}{12}$
1	0	0	$\frac{1}{4}$	$\frac{3}{12}$
$h(x)$	$\frac{109}{432}$	$\frac{154}{432}$	$\frac{169}{432}$	1

3.

$g(p x)$	$x = 0$	1	2
$p = \frac{1}{2}$	$\frac{45}{109}$	$\frac{45}{77}$	$\frac{45}{169}$
$\frac{1}{3}$	$\frac{64}{109}$	$\frac{32}{77}$	$\frac{16}{169}$
1	0	0	$\frac{108}{169}$

Compare the [die-coin experiment](#) with the [box of coins experiment](#). In the first experiment, we toss a coin with a *fixed* probability of heads a *random* number of times. In the second experiment, we effectively toss a coin with a *random* probability of heads a *fixed* number of times.

Suppose that P has probability density function $g(p) = 6p(1 - p)$ for $p \in [0, 1]$. Given $P = p$, a coin with probability of heads p is tossed 3 times. Let X denote the number of heads.

1. Find the joint probability density function of (P, X) .
2. Find the probability density function of X .
3. Find the conditional probability density of P given $X = x$ for $x \in \{0, 1, 2, 3\}$. Graph these on the same axes.

Answer

1. $f(p, x) = 6 \binom{3}{x} p^{x+1} (1-p)^{4-x}$ for $p \in [0, 1]$ and $x \in \{0, 1, 2, 3, 4\}$
2. $h(0) = h(3) = \frac{1}{5}$, $h(1) = h(2) = \frac{3}{10}$.
3. $g(p | 0) = 30p(1-p)^4$, $g(p | 1) = 60p^2(1-p)^3$, $g(p | 2) = 60p^3(1-p)^2$, $g(p | 3) = 30p^4(1-p)$, in each case for $p \in [0, 1]$

Compare the [box of coins experiment](#) with the [last experiment](#). In the second experiment, we effectively choose a coin from a box with a continuous infinity of coin types. The prior distribution of P and each of the posterior distributions of P in part (c) are members of the family of *beta distributions*, one of the reasons for the importance of the beta family. Beta distributions are studied in more detail in the chapter on Special Distributions.

In the simulation of the beta coin experiment, set $a = b = 2$ and $n = 3$ to get the experiment studied in the previous exercise. For various “true values” of p , run the experiment in single step mode a few times and observe the posterior probability density function on each run.

Simple Mixed Distributions

Recall that the *exponential distribution* with rate parameter $r \in (0, \infty)$ has probability density function f given by $f(t) = re^{-rt}$ for $t \in [0, \infty)$. The exponential distribution is often used to model random times, under certain assumptions. The exponential distribution is studied in more detail in the chapter on the Poisson Process. Recall also that for $a, b \in \mathbb{R}$ with $a < b$, the continuous uniform distribution on the interval $[a, b]$ has probability density function f given by $f(x) = \frac{1}{b-a}$ for $x \in [a, b]$. This distribution governs a point selected at random from the interval.

Suppose that there are 5 light bulbs in a box, labeled 1 to 5. The lifetime of bulb n (in months) has the exponential distribution with rate parameter n . A bulb is selected at random from the box and tested.

1. Find the probability that the selected bulb will last more than one month.
2. Given that the bulb lasts more than one month, find the conditional probability density function of the bulb number.

Answer

Let N denote the bulb number and T the lifetime.

1. $\mathbb{P}(T > 1) = 0.1156$

2. n	1	2	3	4	5
$g(n T > 1)$	0.6364	0.2341	0.0861	0.0317	0.0117

Suppose that X is uniformly distributed on $\{1, 2, 3\}$, and given $X = x \in \{1, 2, 3\}$, random variable Y is uniformly distributed on the interval $[0, x]$.

1. Find the joint probability density function of (X, Y) .
2. Find the probability density function of Y .
3. Find the conditional probability density function of X given $Y = y$ for $y \in [0, 3]$.

Answer

1. $f(x, y) = \frac{1}{3x}$ for $y \in [0, x]$ and $x \in \{1, 2, 3\}$.
2. $h(y) = \begin{cases} \frac{11}{18}, & 0 \leq y \leq 1 \\ \frac{5}{18}, & 1 < y \leq 2 \\ \frac{2}{18}, & 2 < y \leq 3 \end{cases}$
3. For $y \in [0, 1]$, $g(1 | y) = \frac{6}{11}$, $g(2 | y) = \frac{3}{11}$, $g(3 | y) = \frac{2}{11}$
 For $y \in (1, 2]$, $g(1 | y) = 0$, $g(2 | y) = \frac{3}{5}$, $g(3 | y) = \frac{2}{5}$
 For $y \in (2, 3]$, $g(1 | y) = g(2 | y) = 0$, $g(3 | y) = 1$.

The Poisson Distribution

Recall that the Poisson distribution with parameter $a \in (0, \infty)$ has probability density function $g(n) = e^{-a} \frac{a^n}{n!}$ for $n \in \mathbb{N}$. This distribution is widely used to model the number of “random points” in a region of time or space; the parameter a is proportional to the size of the region. The Poisson distribution is named for Simeon Poisson, and is studied in more detail in the chapter on the Poisson Process.

Suppose that N is the number of elementary particles emitted by a sample of radioactive material in a specified period of time, and has the Poisson distribution with parameter a . Each particle emitted, independently of the others, is detected by a counter with probability $p \in (0, 1)$ and missed with probability $1 - p$. Let Y denote the number of particles detected by the counter.

1. For $n \in \mathbb{N}$, argue that the conditional distribution of Y given $N = n$ is binomial with parameters n and p .
2. Find the joint probability density function of (N, Y) .
3. Find the probability density function of Y .
4. For $y \in \mathbb{N}$, find the conditional probability density function of N given $Y = y$.

Answer

1. Each particle, independently, is detected (success) with probability p . This is the very definition of Bernoulli trials, so given $N = n$, the number of detected particles has the binomial distribution with parameters n and p .
2. The PDF f of (N, Y) is defined by

$$f(n, y) = e^{-a} a^n \frac{p^y (1-p)^{n-y}}{y! (n-y)!}, \quad n \in \mathbb{N}, y \in \{0, 1, \dots, n\} \quad (3.5.26)$$

3. The PDF h of Y is defined by

$$h(y) = e^{-pa} \frac{(pa)^y}{y!}, \quad y \in \mathbb{N} \quad (3.5.27)$$

This is the Poisson distribution with parameter pa .

4. The conditional PDF of N given $Y = y$ is defined by

$$g(n | y) = e^{-(1-p)a} \frac{[(1-p)a]^{n-y}}{(n-y)!}, \quad n \in \{y, y+1, \dots\} \quad (3.5.28)$$

This is the Poisson distribution with parameter $(1-p)a$, shifted to start at y .

The fact that Y also has a Poisson distribution is an interesting and characteristic property of the distribution. This property is explored in more depth in the section on thinning the Poisson process.

Simple Continuous Distributions

Suppose that (X, Y) has probability density function f defined by $f(x, y) = x + y$ for $(x, y) \in (0, 1)^2$.

1. Find the conditional probability density function of X given $Y = y$ for $y \in (0, 1)$
2. Find the conditional probability density function of Y given $X = x$ for $x \in (0, 1)$
3. Find $\mathbb{P}\left(\frac{1}{4} \leq Y \leq \frac{3}{4} \mid X = \frac{1}{3}\right)$.
4. Are X and Y independent?

Answer

1. For $y \in (0, 1)$, $g(x | y) = \frac{x+y}{y+1/2}$ for $x \in (0, 1)$
2. For $x \in (0, 1)$, $h(y | x) = \frac{x+y}{x+1/2}$ for $y \in (0, 1)$
3. $\frac{1}{2}$
4. X and Y are dependent.

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 2(x + y)$ for $0 < x < y < 1$.

1. Find the conditional probability density function of X given $Y = y$ for $y \in (0, 1)$.
2. Find the conditional probability density function of Y given $X = x$ for $x \in (0, 1)$.
3. Find $\mathbb{P}\left(Y \geq \frac{3}{4} \mid X = \frac{1}{2}\right)$.
4. Are X and Y independent?

Answer

1. For $y \in (0, 1)$, $g(x | y) = \frac{x+y}{3y^2}$ for $x \in (0, y)$.
2. For $x \in (0, 1)$, $h(y | x) = \frac{x+y}{(1+3x)(1-x)}$ for $y \in (x, 1)$.
3. $\frac{3}{10}$
4. X and Y are dependent.

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 15x^2y$ for $0 < x < y < 1$.

1. Find the conditional probability density function of X given $Y = y$ for $y \in (0, 1)$.
2. Find the conditional probability density function of Y given $X = x$ for $x \in (0, 1)$.
3. Find $\mathbb{P}\left(X \leq \frac{1}{4} \mid Y = \frac{1}{3}\right)$.
4. Are X and Y independent?

Answer

1. For $y \in (0, 1)$, $g(x \mid y) = \frac{3x^2}{y^3}$ for $x \in (0, y)$.
2. For $x \in (0, 1)$, $h(y \mid x) = \frac{2y}{1-x^2}$ for $y \in (x, 1)$.
3. $\frac{27}{64}$
4. X and Y are dependent.

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 6x^2y$ for $0 < x < 1$ and $0 < y < 1$.

1. Find the conditional probability density function of X given $Y = y$ for $y \in (0, 1)$.
2. Find the conditional probability density function of Y given $X = x$ for $x \in (0, 1)$.
3. Are X and Y independent?

Answer

1. For $y \in (0, 1)$, $g(x \mid y) = 3x^2$ for $y \in (0, 1)$.
2. For $x \in (0, 1)$, $h(y \mid x) = 2y$ for $y \in (0, 1)$.
3. X and Y are independent.

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 2e^{-x}e^{-y}$ for $0 < x < y < \infty$.

1. Find the conditional probability density function of X given $Y = y$ for $y \in (0, \infty)$.
2. Find the conditional probability density function of Y given $X = x$ for $x \in (0, \infty)$.
3. Are X and Y independent?

Answer

1. For $y \in (0, \infty)$, $g(x \mid y) = \frac{e^{-x}}{1-e^{-y}}$ for $x \in (0, y)$.
2. For $x \in (0, \infty)$, $h(y \mid x) = e^{x-y}$ for $y \in (x, \infty)$.
3. X and Y are dependent.

Suppose that X is uniformly distributed on the interval $(0, 1)$, and that given $X = x$, Y is uniformly distributed on the interval $(0, x)$.

1. Find the joint probability density function of (X, Y) .
2. Find the probability density function of Y .
3. Find the conditional probability density function of X given $Y = y$ for $y \in (0, 1)$.
4. Are X and Y independent?

Answer

1. $f(x, y) = \frac{1}{x}$ for $0 < y < x < 1$
2. $h(y) = -\ln y$ for $y \in (0, 1)$
3. For $y \in (0, 1)$, $g(x \mid y) = -\frac{1}{x \ln y}$ for $x \in (y, 1)$.
4. X and Y are dependent.

Suppose that X has probability density function g defined by $g(x) = 3x^2$ for $x \in (0, 1)$. The conditional probability density function of Y given $X = x$ is $h(y \mid x) = \frac{3y^2}{x^3}$ for $y \in (0, x)$.

1. Find the joint probability density function of (X, Y) .
2. Find the probability density function of Y .
3. Find the conditional probability density function of X given $Y = y$.
4. Are X and Y independent?

Answer

1. $f(x, y) = \frac{9y^2}{x}$ for $0 < y < x < 1$.
2. $h(y) = -9y^2 \ln y$ for $y \in (0, 1)$.

3. For $y \in (0, 1)$, $g(x | y) = -\frac{1}{x \ln y}$ for $x \in (y, 1)$.
4. X and Y are dependent.

Multivariate Uniform Distributions

Multivariate uniform distributions give a geometric interpretation of some of the concepts in this section.

Recall that For $n \in \mathbb{N}_+$, the standard measure λ_n on \mathbb{R}^n is given by

$$\lambda_n(A) = \int_A 1 \, dx, \quad A \subseteq \mathbb{R}^n \quad (3.5.29)$$

In particular, $\lambda_1(A)$ is the length of $A \subseteq \mathbb{R}$, $\lambda_2(A)$ is the area of $A \subseteq \mathbb{R}^2$ and $\lambda_3(A)$ is the volume of $A \subseteq \mathbb{R}^3$.

Details

Technically, λ_n is Lebesgue measure defined on the σ -algebra of measurable subsets of \mathbb{R}^n . In the discussion below, we assume that all sets are measurable. The integral representation is valid for the sets that occur in typical applications.

Suppose now that X takes values in \mathbb{R}^j , Y takes values in \mathbb{R}^k , and that (X, Y) is uniformly distributed on a set $R \subseteq \mathbb{R}^{j+k}$. So $0 < \lambda_{j+k}(R) < \infty$ and then the joint probability density function f of (X, Y) is given by $f(x, y) = 1/\lambda_{j+k}(R)$ for $(x, y) \in R$. Now let S and T be the projections of R onto \mathbb{R}^j and \mathbb{R}^k respectively, defined as follows:

$$S = \{x \in \mathbb{R}^j : (x, y) \in R \text{ for some } y \in \mathbb{R}^k\}, \quad T = \{y \in \mathbb{R}^k : (x, y) \in R \text{ for some } x \in \mathbb{R}^j\} \quad (3.5.30)$$

Note that $R \subseteq S \times T$. Next we denote the cross sections at $x \in S$ and at $y \in T$, respectively by

$$T_x = \{t \in T : (x, t) \in R\}, \quad S_y = \{s \in S : (s, y) \in R\} \quad (3.5.31)$$

Figure 3.5.1: The projections S and T , and the cross sections at x and y

In the last section on Joint Distributions, we saw that even though (X, Y) is uniformly distributed, the marginal distributions of X and Y are not uniform in general. However, as the next theorem shows, the conditional distributions are always uniform.

Suppose that (X, Y) is uniformly distributed on R . Then

1. The conditional distribution of Y given $X = x$ is uniformly on T_x for each $x \in S$.
2. The conditional distribution of X given $Y = y$ is uniformly on S_y for each $y \in T$.

Proof

The results are symmetric, so we will prove (a). Recall that X has PDF g given by

$$g(x) = \int_{T_x} f(x, y) \, dy = \int_{T_x} \frac{1}{\lambda_{j+k}(R)} \, dy = \frac{\lambda_k(T_x)}{\lambda_{j+k}(R)}, \quad x \in S \quad (3.5.32)$$

Hence for $x \in S$, the conditional PDF of Y given $X = x$ is

$$h(y | x) = \frac{f(x, y)}{g(x)} = \frac{1}{\lambda_k(T_x)}, \quad y \in T_x \quad (3.5.33)$$

and this is the PDF of the uniform distribution on T_x .

Find the conditional density of each variable given a value of the other, and determine if the variables are independent, in each of the following cases:

1. (X, Y) is uniformly distributed on the square $R = (-6, 6)^2$.

2. (X, Y) is uniformly distributed on the triangle $R = \{(x, y) \in \mathbb{R}^2 : -6 < y < x < 6\}$.
3. (X, Y) is uniformly distributed on the circle $R = \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 < 36\}$.

Answer

The conditional PDF of X given $Y = y$ is denoted $x \mapsto g(x | y)$. The conditional PDF of Y given $X = x$ is denoted $y \mapsto h(y | x)$.

1.
 - For $y \in (-6, 6)$, $g(x | y) = \frac{1}{12}$ for $x \in (-6, 6)$.
 - For $x \in (-6, 6)$, $h(y | x) = \frac{1}{12}$ for $y \in (-6, 6)$.
 - X, Y are independent.
2.
 - For $y \in (-6, 6)$, $g(x | y) = \frac{1}{6-y}$ for $x \in (y, 6)$
 - For $x \in (-6, 6)$, $h(y | x) = \frac{1}{x+6}$ for $y \in (-6, x)$
 - X, Y are dependent.
3.
 - For $y \in (-6, 6)$, $g(x | y) = \frac{1}{2\sqrt{36-y^2}}$ for $x \in (-\sqrt{36-y^2}, \sqrt{36-y^2})$
 - For $x \in (-6, 6)$, $g(x | y) = \frac{1}{2\sqrt{36-x^2}}$ for $y \in (-\sqrt{36-x^2}, \sqrt{36-x^2})$
 - X, Y are dependent.

In the bivariate uniform experiment, run the simulation 1000 times in each of the following cases. Watch the points in the scatter plot and the graphs of the marginal distributions.

1. square
2. triangle
3. circle

Suppose that (X, Y, Z) is uniformly distributed on $R = \{(x, y, z) \in \mathbb{R}^3 : 0 < x < y < z < 1\}$.

1. Find the conditional density of each pair of variables given a value of the third variable.
2. Find the conditional density of each variable given values of the other two.

Answer

The subscripts 1, 2, and 3 correspond to the variables X, Y , and Z , respectively. Note that the conditions on (x, y, z) in each case are those in the definition of the domain R . They are stated differently to emphasize the domain of the conditional PDF as opposed to the given values, which function as parameters. Note also that each distribution is uniform on the appropriate region.

1. For $0 < z < 1$, $f_{1,2|3}(x, y | z) = \frac{2}{z^2}$ for $0 < x < y < z$
2. For $0 < y < 1$, $f_{1,3|2}(x, z | y) = \frac{1}{y(1-y)}$ for $0 < x < y$ and $y < z < 1$
3. For $0 < x < 1$, $f_{2,3|1}(y, z | x) = \frac{2}{(1-x)^2}$ for $x < y < z < 1$
4. For $0 < y < z < 1$, $f_{1|2,3}(x | y, z) = \frac{1}{y}$ for $0 < x < y$
5. For $0 < x < z < 1$, $f_{2|1,3}(y | x, z) = \frac{1}{z-x}$ for $x < y < z$
6. For $0 < x < y < 1$, $f_{3|1,2}(z | x, y) = \frac{1}{1-y}$ for $y < z < 1$

The Multivariate Hypergeometric Distribution

Recall the discussion of the (multivariate) hypergeometric distribution given in the last section on joint distributions. As in that discussion, suppose that a population consists of m objects, and that each object is one of four types. There are a objects of type 1, b objects of type 2, and c objects of type 3, and $m - a - b - c$ objects of type 0. We sample n objects from the population at random, and without replacement. The parameters a, b, c , and n are nonnegative integers with $a + b + c \leq m$ and $n \leq m$. Denote the number of type 1, 2, and 3 objects in the sample by X, Y , and Z , respectively. Hence, the number of type 0 objects in the sample is $n - X - Y - Z$. In the following exercises, $x, y, z \in \mathbb{N}$.

Suppose that $z \leq c$ and $n - m + c \leq z \leq n$. Then the conditional distribution of (X, Y) given $Z = z$ is hypergeometric, and has the probability density function defined by

$$g(x, y | z) = \frac{\binom{a}{x} \binom{b}{y} \binom{m-a-b-c}{n-x-y-z}}{\binom{m-c}{n-z}}, \quad x + y \leq n - z \quad (3.5.34)$$

Proof

This result can be proved analytically but a combinatorial argument is better. The essence of the argument is that we are selecting a random sample of size $n - z$ without replacement from a population of size $m - c$, with a objects of type 1, b objects of type 2, and $m - a - b - c$ objects of type 0. The conditions on z ensure that $\mathbb{P}(Z = z) > 0$, or equivalently, that the new parameters make sense.

Suppose that $y \leq b$, $z \leq c$, and $n - m + b \leq y + z \leq n$. Then the conditional distribution of X given $Y = y$ and $Z = z$ is hypergeometric, and has the probability density function defined by

$$g(x | y, z) = \frac{\binom{a}{x} \binom{m-a-b-c}{n-x-y-z}}{\binom{m-b-c}{n-y-z}}, \quad x \leq n - y - z \quad (3.5.35)$$

Proof

Again, this result can be proved analytically, but a combinatorial argument is better. The essence of the argument is that we are selecting a random sample of size $n - y - z$ from a population of size $m - b - c$, with a objects of type 1 and $m - a - b - c$ objects type 0. The conditions on y and z ensure that $\mathbb{P}(Y = y, Z = z) > 0$, or equivalently that the new parameters make sense.

These results generalize in a completely straightforward way to a population with any number of types. In brief, if a random vector has a hypergeometric distribution, then the conditional distribution of some of the variables, given values of the other variables, is also hypergeometric. Moreover, it is clearly not necessary to remember the hideous formulas in the previous two theorems. You just need to recognize the problem as sampling without replacement from a multi-type population, and then identify the number of objects of each type and the sample size. The hypergeometric distribution and the multivariate hypergeometric distribution are studied in more detail in the chapter on Finite Sampling Models.

In a population of 150 voters, 60 are democrats and 50 are republicans and 40 are independents. A sample of 15 voters is selected at random, without replacement. Let X denote the number of democrats in the sample and Y the number of republicans in the sample. Give the probability density function of each of the following:

1. (X, Y)
2. X
3. Y given $X = 5$

Answer

1. $f(x, y) = \frac{1}{\binom{150}{15}} \binom{60}{x} \binom{50}{y} \binom{40}{15-x-y}$ for $x + y \leq 15$
2. $g(x) = \frac{1}{\binom{150}{15}} \binom{60}{x} \binom{90}{15-x}$ for $x \leq 15$
3. $h(y | 5) = \frac{1}{\binom{90}{10}} \binom{50}{y} \binom{40}{10-y}$ for $y \leq 10$

Recall that a *bridge hand* consists of 13 cards selected at random and without replacement from a standard deck of 52 cards. Let X , Y , and Z denote the number of spades, hearts, and diamonds, respectively, in the hand. Find the probability density function of each of the following:

1. (X, Y, Z)
2. (X, Y)
3. X
4. (X, Y) given $Z = 3$
5. X given $Y = 3$ and $Z = 2$

Answer

1. $f(x, y, z) = \frac{1}{\binom{52}{13}} \binom{13}{x} \binom{13}{y} \binom{13}{z} \binom{13}{13-x-y-z}$ for $x + y + z \leq 13$.
2. $g(x, y) = \frac{1}{\binom{52}{13}} \binom{13}{x} \binom{13}{y} \binom{26}{13-x-y}$ for $x + y \leq 13$
3. $h(x) = \frac{1}{\binom{52}{13}} \binom{13}{x} \binom{39}{13-x}$ for $x \leq 13$
4. $g(x, y | 3) = \frac{1}{\binom{39}{10}} \binom{13}{x} \binom{13}{y} \binom{13}{10-x-y}$ for $x + y \leq 10$
5. $h(x | 3, 2) = \frac{1}{\binom{26}{8}} \binom{13}{x} \binom{13}{8-x}$ for $x \leq 8$

Multinomial Trials

Recall the discussion of *multinomial trials* in the last section on joint distributions. As in that discussion, suppose that we have a sequence of n independent trials, each with 4 possible outcomes. On each trial, outcome 1 occurs with probability p , outcome 2 with probability q , outcome 3 with probability r , and outcome 0 with probability $1 - p - q - r$. The parameters $p, q, r \in (0, 1)$, with $p + q + r < 1$, and $n \in \mathbb{N}_+$. Denote the number of times that outcome 1, outcome 2, and outcome 3 occurs in the n trials by X, Y , and Z respectively. Of course, the number of times that outcome 0 occurs is $n - X - Y - Z$. In the following exercises, $x, y, z \in \mathbb{N}$.

For $z \leq n$, the conditional distribution of (X, Y) given $Z = z$ is also multinomial, and has the probability density function.

$$g(x, y | z) = \binom{n-z}{x, y} \left(\frac{p}{1-r} \right)^x \left(\frac{q}{1-r} \right)^y \left(1 - \frac{p}{1-r} - \frac{q}{1-r} \right)^{n-x-y-z}, \quad x + y \leq n - z \quad (3.5.36)$$

Proof

This result can be proved analytically, but a probability argument is better. First, let I denote the outcome of a generic trial. Then $\mathbb{P}(I = 1 | I \neq 3) = \mathbb{P}(I = 1) / \mathbb{P}(I \neq 3) = p / (1 - r)$. Similarly, $\mathbb{P}(I = 2 | I \neq 3) = q / (1 - r)$ and $\mathbb{P}(I = 0 | I \neq 3) = (1 - p - q - r) / (1 - r)$. Now, the essence of the argument is that effectively, we have $n - z$ independent trials, and on each trial, outcome 1 occurs with probability $p / (1 - r)$ and outcome 2 with probability $q / (1 - r)$.

For $y + z \leq n$, the conditional distribution of X given $Y = y$ and $Z = z$ is binomial, with the probability density function

$$h(x | y, z) = \binom{n-y-z}{x} \left(\frac{p}{1-q-r} \right)^x \left(1 - \frac{p}{1-q-r} \right)^{n-x-y-z}, \quad x \leq n - y - z \quad (3.5.37)$$

Proof

Again, this result can be proved analytically, but a probability argument is better. As before, let I denote the outcome of a generic trial. Then $\mathbb{P}(I = 1 | I \notin \{2, 3\}) = p / (1 - q - r)$ and $\mathbb{P}(I = 0 | I \notin \{2, 3\}) = (1 - p - q - r) / (1 - q - r)$. Thus, the essence of the argument is that effectively, we have $n - y - z$ independent trials, and on each trial, outcome 1 occurs with probability $p / (1 - q - r)$.

These results generalize in a completely straightforward way to multinomial trials with any number of trial outcomes. In brief, if a random vector has a multinomial distribution, then the conditional distribution of some of the variables, given values of the other variables, is also multinomial. Moreover, it is clearly not necessary to remember the specific formulas in the previous two exercises. You just need to recognize a problem as one involving independent trials, and then identify the probability of each outcome and the number of trials. The binomial distribution and the multinomial distribution are studied in more detail in the chapter on Bernoulli Trials.

Suppose that peaches from an orchard are classified as *small*, *medium*, or *large*. Each peach, independently of the others is small with probability $\frac{3}{10}$, medium with probability $\frac{1}{2}$, and large with probability $\frac{1}{5}$. In a sample of 20 peaches from the orchard, let X denote the number of small peaches and Y the number of medium peaches. Give the probability density function of each of the following:

1. (X, Y)
2. X
3. Y given $X = 5$

Answer

1. $f(x, y) = \binom{20}{x, y} \left(\frac{3}{10} \right)^x \left(\frac{1}{2} \right)^y \left(\frac{1}{5} \right)^{20-x-y}$ for $x + y \leq 20$
2. $g(x) = \binom{20}{x} \left(\frac{3}{10} \right)^x \left(\frac{7}{10} \right)^{20-x}$ for $x \leq 20$
3. $h(y | 5) = \binom{15}{y} \left(\frac{5}{7} \right)^y \left(\frac{2}{7} \right)^{15-y}$ for $y \leq 15$

For a certain crooked, 4-sided die, face 1 has probability $\frac{2}{5}$, face 2 has probability $\frac{3}{10}$, face 3 has probability $\frac{1}{5}$, and face 4 has probability $\frac{1}{10}$. Suppose that the die is thrown 50 times. Let X, Y , and Z denote the number of times that scores 1, 2, and 3 occur, respectively. Find the probability density function of each of the following:

1. (X, Y, Z)
2. (X, Y)
3. X
4. (X, Y) given $Z = 5$

5. X given $Y = 10$ and $Z = 5$

Answer

1. $f(x, y, z) = \binom{50}{x, y, z} \left(\frac{2}{5}\right)^x \left(\frac{3}{10}\right)^y \left(\frac{1}{5}\right)^z \left(\frac{1}{10}\right)^{50-x-y-z}$ for $x + y + z \leq 50$
2. $g(x, y) = \binom{50}{x, y} \left(\frac{2}{5}\right)^x \left(\frac{3}{10}\right)^y \left(\frac{3}{10}\right)^{50-x-y}$ for $x + y \leq 50$
3. $h(x) = \binom{50}{x} \left(\frac{2}{5}\right)^x \left(\frac{3}{5}\right)^{50-x}$ for $x \leq 50$
4. $g(x, y | 5) = \binom{45}{x, y} \left(\frac{1}{2}\right)^x \left(\frac{3}{8}\right)^y \left(\frac{1}{8}\right)^{45-x-y}$ for $x + y \leq 45$
5. $h(x | 10, 5) = \binom{35}{x} \left(\frac{4}{5}\right)^x \left(\frac{1}{4}\right)^{10-x}$ for $x \leq 35$

Bivariate Normal Distributions

The joint distributions in the next two exercises are examples of *bivariate normal distributions*. The conditional distributions are also normal, an important property of the bivariate normal distribution. In general, normal distributions are widely used to model physical measurements subject to small, random errors. The bivariate normal distribution is studied in more detail in the chapter on Special Distributions.

Suppose that (X, Y) has the bivariate normal distribution with probability density function f defined by

$$f(x, y) = \frac{1}{12\pi} \exp\left[-\left(\frac{x^2}{8} + \frac{y^2}{18}\right)\right], \quad (x, y) \in \mathbb{R}^2 \quad (3.5.38)$$

1. Find the conditional probability density function of X given $Y = y$ for $y \in \mathbb{R}$.
2. Find the conditional probability density function of Y given $X = x$ for $x \in \mathbb{R}$.
3. Are X and Y independent?

Answer

1. For $y \in \mathbb{R}$, $g(x | y) = \frac{1}{2\sqrt{2\pi}} e^{-x^2/8}$ for $x \in \mathbb{R}$. This is the PDF of the normal distribution with mean 0 and variance 4.
2. For $x \in \mathbb{R}$, $h(y | x) = \frac{1}{3\sqrt{2\pi}} e^{-y^2/18}$ for $y \in \mathbb{R}$. This is the PDF of the normal distribution with mean 0 and variance 9.
3. X and Y are independent.

Suppose that (X, Y) has the bivariate normal distribution with probability density function f defined by

$$f(x, y) = \frac{1}{\sqrt{3}\pi} \exp\left[-\frac{2}{3}(x^2 - xy + y^2)\right], \quad (x, y) \in \mathbb{R}^2 \quad (3.5.39)$$

1. Find the conditional probability density function of X given $Y = y$ for $y \in \mathbb{R}$.
2. Find the conditional probability density function of Y given $X = x$ for $x \in \mathbb{R}$.
3. Are X and Y independent?

Answer

1. For $y \in \mathbb{R}$, $g(x | y) = \sqrt{\frac{2}{3\pi}} e^{-\frac{2}{3}(x-y/2)^2}$ for $x \in \mathbb{R}$. This is the PDF of the normal distribution with mean $y/2$ and variance $3/4$.
2. For $x \in \mathbb{R}$, $h(y | x) = \sqrt{\frac{2}{3\pi}} e^{-\frac{2}{3}(y-x/2)^2}$ for $y \in \mathbb{R}$. This is the PDF of the normal distribution with mean $x/2$ and variance $3/4$.
3. X and Y are dependent.

Mixtures of Distributions

With our usual sets S and T , as above, suppose that P_x is a probability measure on T for each $x \in S$. Suppose also that g is a probability density function on S . We can obtain a new probability measure on T by averaging (or *mixing*) the given distributions according to g .

First suppose that g is the probability density function of a discrete distribution on the countable set S . Then the function \mathbb{P} defined below is a probability measure on T :

$$\mathbb{P}(B) = \sum_{x \in S} g(x) P_x(B), \quad B \subseteq T \quad (3.5.40)$$

Proof

Clearly $\mathbb{P}(B) \geq 0$ for $B \subseteq T$ and $\mathbb{P}(T) = \sum_{x \in S} g(x) 1 = 1$. Suppose that $\{B_i : i \in I\}$ is a countable, disjoint collection of subsets of T . Then

$$\mathbb{P}\left(\bigcup_{i \in I} B_i\right) = \sum_{x \in S} g(x) P_x\left(\bigcup_{i \in I} B_i\right) = \sum_{x \in S} g(x) \sum_{i \in I} P_x(B_i) = \sum_{i \in I} \sum_{x \in S} g(x) P_x(B_i) = \sum_{i \in I} \mathbb{P}(B_i) \quad (3.5.41)$$

Reversing the order of summation is justified since the terms are nonnegative.

In the setting of the previous theorem, suppose that P_x has probability density function h_x for each $x \in S$. Then \mathbb{P} has probability density function h given by

$$h(y) = \sum_{x \in S} g(x) h_x(y), \quad y \in T \quad (3.5.42)$$

Proof

As usual, we will consider the discrete and continuous cases for the distributions on T separately.

1. Suppose that T is countable so that P_x is a discrete probability measure for each $x \in S$. By definition, for each $x \in S$, $h_x(y) = \mathbb{P}_x(\{y\})$ for $y \in T$. So the probability density function h of P is given by

$$h(y) = P(\{y\}) = \sum_{x \in S} g(x) P_x(\{y\}) = \sum_{x \in S} g(x) h_x(y), \quad y \in T \quad (3.5.43)$$

2. Suppose now that P_x has a continuous distribution on $T \subseteq \mathbb{R}^k$, with PDF g_x for each $x \in S$. For $B \subseteq T$,

$$\mathbb{P}(B) = \sum_{x \in S} g(x) P_x(B) = \sum_{x \in S} g(x) \int_B h_x(y) dy = \int_B \sum_{x \in S} g(x) h_x(y) dy = \int_B h(y) dy \quad (3.5.44)$$

So by definition, h is the PDF of \mathbb{P} . Again, the interchange of sum and integral is justified because the functions are nonnegative. Technically, we also need $y \mapsto h_x(y)$ to be measurable for $x \in S$ so that the integral makes sense.

Conversely, given a probability density function g on S and a probability density function h_x on T for each $x \in S$, the function h defined in the previous theorem is a probability density function on T .

Suppose now that g is the probability density function of a continuous distribution on $S \subseteq \mathbb{R}^j$. Then the function \mathbb{P} defined below is a probability measure on T :

$$\mathbb{P}(B) = \int_S g(x) P_x(B) dx, \quad B \subseteq T \quad (3.5.45)$$

Proof

The proof is just like the proof of Theorem (45) with integrals over S replacing the sums over S . Clearly $\mathbb{P}(B) \geq 0$ for $B \subseteq T$ and $\mathbb{P}(T) = \int_S g(x) P_x(T) dx = \int_S g(x) dx = 1$. Suppose that $\{B_i : i \in I\}$ is a countable, disjoint collection of subsets of T . Then

$$\mathbb{P}\left(\bigcup_{i \in I} B_i\right) = \int_S g(x) P_x\left(\bigcup_{i \in I} B_i\right) dx = \int_S g(x) \sum_{i \in I} P_x(B_i) dx = \sum_{i \in I} \int_S g(x) P_x(B_i) dx = \sum_{i \in I} \mathbb{P}(B_i) \quad (3.5.46)$$

Reversing the integral and the sum is justified since the terms are nonnegative. Technically, we need the subsets of T and the mapping $x \mapsto P_x(B)$ to be measurable.

In the setting of the previous theorem, suppose that P_x is a discrete (respectively continuous) distribution with probability density function h_x for each $x \in S$. Then \mathbb{P} is also discrete (respectively continuous) with probability density function h given by

$$h(y) = \int_S g(x) h_x(y) dx, \quad y \in T \quad (3.5.47)$$

Proof

The proof is just like the proof of Theorem (46) with integrals over S replacing the sums over S .

1. Suppose that T is countable so that P_x is a discrete probability measure for each $x \in S$. By definition, for each $x \in S$, $h_x(y) = \mathbb{P}_x(\{y\})$ for $y \in T$. So the probability density function h of P is given by

$$h(y) = P(\{y\}) = \int_S g(x)P_x(\{y\}) dx = \int_S g(x)h_x(y) dx, \quad y \in T \quad (3.5.48)$$

Technically, we need $x \mapsto P_x(\{y\}) = h_x(y)$ to be measurable for $y \in T$.

2. Suppose now that P_x has a continuous distribution on $T \subseteq \mathbb{R}^k$, with PDF g_x for each $x \in S$. For $B \subseteq T$,

$$\mathbb{P}(B) = \int_S g(x)P_x(B) dx = \int_S g(x) \int_B h_x(y) dy dx = \int_B \int_S g(x)h_x(y) dx dy = \int_B h(y) dy \quad (3.5.49)$$

So by definition, h is the PDF of \mathbb{P} . Again, the interchange of sum and integral is justified because the functions are nonnegative.

Technically, we also need $(x, y) \mapsto h_x(y)$ to be measurable so that the integral makes sense.

In both cases, the distribution \mathbb{P} is said to be a *mixture* of the set of distributions $\{P_x : x \in S\}$, with mixing density g .

One can have a mixture of distributions, without having random variables defined on a common probability space. However, mixtures are intimately related to conditional distributions. Returning to our usual setup, suppose that X and Y are random variables for an experiment, taking values in S and T respectively and that X probability density function g . The following result is simply a restatement of the law of total probability.

The distribution of Y is a mixture of the conditional distributions of Y given $X = x$, over $x \in S$, with mixing density g .

Proof

Only the notation is different.

1. If X has a discrete distribuion on the countable set S then

$$\mathbb{P}(Y \in B) = \sum_{x \in S} g(x)\mathbb{P}(Y \in B \mid X = x), \quad B \subseteq T \quad (3.5.50)$$

2. If X has a continuous distribution $S \subseteq \mathbb{R}^j$ then

$$\mathbb{P}(Y \in B) = \int_S g(x)\mathbb{P}(Y \in B \mid X = x) dx, \quad B \subseteq T \quad (3.5.51)$$

Finally we note that a mixed distribution (with discrete and continuous parts) really is a mixture, in the sense of this discussion.

Suppose that \mathbb{P} is a mixed distribution on a set T . Then \mathbb{P} is a mixture of a discrete distribution and a continuous distribution.

Proof

Recall that *mixed distribution* means that T can be partitioned into a countable set D and a set $C \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$ with the properties that $\mathbb{P}(\{x\}) > 0$ for $x \in D$, $\mathbb{P}(\{x\}) = 0$ for $x \in C$, and $p = \mathbb{P}(D) \in (0, 1)$. Let $S = \{d, c\}$ and define the PDF g on S by $g(d) = p$ and $g(c) = 1 - p$. Recall that the conditional distribution P_d defined by $P_d(A) = \mathbb{P}(A \cap D)/\mathbb{P}(D)$ for $A \subseteq T$ is a discrete distribution on T and similarly the conditional distribution P_c defined by $P_c(A) = \mathbb{P}(A \cap C)/\mathbb{P}(C)$ for $A \subseteq T$ is a continuous distribution on T . Clearly with this setup,

$$\mathbb{P}(A) = g(c)P_c(A) + g(d)P_d(A), \quad A \subseteq T \quad (3.5.52)$$

This page titled [3.5: Conditional Distributions](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

3.6: Distribution and Quantile Functions

As usual, our starting point is a random experiment modeled by a with probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} is the collection of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . In this section, we will study two types of functions that can be used to specify the distribution of a real-valued random variable.

Distribution Functions

Definition

Suppose that X is a random variable with values in \mathbb{R} . The (cumulative) *distribution function* of X is the function $F : \mathbb{R} \rightarrow [0, 1]$ defined by

$$F(x) = \mathbb{P}(X \leq x), \quad x \in \mathbb{R} \quad (3.6.1)$$

The distribution function is important because it makes sense for any type of random variable, regardless of whether the distribution is discrete, continuous, or even mixed, and because it completely determines the distribution of X . In the picture below, the light shading is intended to represent a continuous distribution of probability, while the darker dots represents points of positive probability; $F(x)$ is the total probability mass to the left of (and including) x .

Figure 3.6.1: $F(x)$ is the total probability to the left of (and including) x

Basic Properties

A few basic properties completely characterize distribution functions. Notationally, it will be helpful to abbreviate the limits of F from the left and right at $x \in \mathbb{R}$, and at ∞ and $-\infty$ as follows:

$$F(x^+) = \lim_{t \downarrow x} F(t), \quad F(x^-) = \lim_{t \uparrow x} F(t), \quad F(\infty) = \lim_{t \rightarrow \infty} F(t), \quad F(-\infty) = \lim_{t \rightarrow -\infty} F(t) \quad (3.6.2)$$

Suppose that F is the distribution function of a real-valued random variable X .

1. F is increasing: if $x \leq y$ then $F(x) \leq F(y)$.
2. $F(x^+) = F(x)$ for $x \in \mathbb{R}$. Thus, F is *continuous from the right*.
3. $F(x^-) = \mathbb{P}(X < x)$ for $x \in \mathbb{R}$. Thus, F has *limits from the left*.
4. $F(-\infty) = 0$.
5. $F(\infty) = 1$.

Proof

Figure 3.6.2: The graph of a distribution function

The following result shows how the distribution function can be used to compute the probability that X is in an interval. Recall that a probability distribution on \mathbb{R} is completely determined by the probabilities of *intervals*; thus, the *distribution function* determines

the *distribution* of X .

Suppose again that F is the distribution function of a real-valued random variable X . If $a, b \in \mathbb{R}$ with $a < b$ then

1. $\mathbb{P}(X = a) = F(a) - F(a^-)$
2. $\mathbb{P}(a < X \leq b) = F(b) - F(a)$
3. $\mathbb{P}(a < X < b) = F(b^-) - F(a)$
4. $\mathbb{P}(a \leq X \leq b) = F(b) - F(a^-)$
5. $\mathbb{P}(a \leq X < b) = F(b^-) - F(a^-)$

Proof

These results follow from the [definition](#), the [basic properties](#), and the difference rule: $\mathbb{P}(B \setminus A) = \mathbb{P}(B) - \mathbb{P}(A)$ if A, B are events and $A \subseteq B$.

1. $\{X = a\} = \{X \leq a\} \setminus \{X < a\}$, so $\mathbb{P}(X = a) = \mathbb{P}(X \leq a) - \mathbb{P}(X < a) = F(a) - F(a^-)$.
2. $\{a < X \leq b\} = \{X \leq b\} \setminus \{X \leq a\}$, so $\mathbb{P}(a < X \leq b) = \mathbb{P}(X \leq b) - \mathbb{P}(X \leq a) = F(b) - F(a)$.
3. $\{a < X < b\} = \{X < b\} \setminus \{X \leq a\}$, so $\mathbb{P}(a < X < b) = \mathbb{P}(X < b) - \mathbb{P}(X \leq a) = F(b^-) - F(a)$.
4. $\{a \leq X \leq b\} = \{X \leq b\} \setminus \{X < a\}$, so $\mathbb{P}(a \leq X \leq b) = \mathbb{P}(X \leq b) - \mathbb{P}(X < a) = F(b) - F(a^-)$.
5. $\{a \leq X < b\} = \{X < b\} \setminus \{X < a\}$, so $\mathbb{P}(a \leq X < b) = \mathbb{P}(X < b) - \mathbb{P}(X < a) = F(b^-) - F(a^-)$.

Conversely, if a Function $F : \mathbb{R} \rightarrow [0, 1]$ satisfies the [basic properties](#), then the [formulas above](#) define a probability distribution on \mathbb{R} , with F as the distribution function. For more on this point, read the section on Existence and Uniqueness.

If X has a continuous distribution, then the distribution function F is continuous.

Proof

If X has a continuous distribution, then by definition, $\mathbb{P}(X = x) = 0$ so $\mathbb{P}(X < x) = \mathbb{P}(X \leq x)$ for $x \in \mathbb{R}$. Hence from part (a) of the [previous theorem](#), $F(x^-) = F(x^+) = F(x)$.

Thus, the two meanings of *continuous* come together: continuous distribution and continuous function in the calculus sense. Next recall that the distribution of a real-valued random variable X is *symmetric* about a point $a \in \mathbb{R}$ if the distribution of $X - a$ is the same as the distribution of $a - X$.

Suppose that X has a continuous distribution on \mathbb{R} that is symmetric about a point a . Then the distribution function F satisfies $F(a - t) = 1 - F(a + t)$ for $t \in \mathbb{R}$.

Proof

Since $X - a$ and $a - X$ have the same distribution,

$$F(a - t) = \mathbb{P}(X \leq a - t) = \mathbb{P}(X - a \leq -t) = \mathbb{P}(a - X \leq -t) = \mathbb{P}(X \geq a + t) = 1 - F(a + t) \quad (3.6.3)$$

Relation to Density Functions

There are simple relationships between the distribution function and the probability density function. Recall that if X takes value in $S \subseteq \mathbb{R}$ and has probability density function f , we can extend f to all of \mathbb{R} by the convention that $f(x) = 0$ for $x \in S^c$. As in Definition (1), it's customary to define the distribution function F on all of \mathbb{R} , even if the random variable takes values in a subset.

Suppose that X has discrete distribution on a countable subset $S \subseteq \mathbb{R}$. Let f denote the probability density function and F the distribution function.

1. $F(x) = \sum_{t \in S, t \leq x} f(t)$ for $x \in \mathbb{R}$
2. $f(x) = F(x) - F(x^-)$ for $x \in S$

Proof

1. This follows from the definition of the PDF of X , $f(t) = \mathbb{P}(X = t)$ for $t \in S$, and the additivity of probability.
2. This is a restatement of part (a) of the [theorem above](#).

Thus, F is a step function with jumps at the points in S ; the size of the jump at x is $f(x)$.

Figure 3.6.3: The distribution function of a discrete distribution

There is an analogous result for a continuous distribution with a probability density function.

Suppose that X has a continuous distribution on \mathbb{R} with probability density function f and distribution function F .

1. $F(x) = \int_{-\infty}^x f(t)dt$ for $x \in \mathbb{R}$.
2. $f(x) = F'(x)$ if f is continuous at x .

Proof

Figure 3.6.4: The distribution function of a continuous distribution

The last result is the basic probabilistic version of the fundamental theorem of calculus. For mixed distributions, we have a combination of the results in the last two theorems.

Suppose that X has a mixed distribution, with discrete part on a countable subset $D \subseteq \mathbb{R}$, and continuous part on $\mathbb{R} \setminus D$. Let g denote the partial probability density function of the discrete part and assume that the continuous part has partial probability density function h . Let F denote the distribution function.

1. $F(x) = \sum_{t \in D, t \leq x} g(t) + \int_{-\infty}^x h(t)dt$ for $x \in \mathbb{R}$
2. $g(x) = F(x) - F(x^-)$ for $x \in D$
3. $h(x) = F'(x)$ if $x \notin D$ and h is continuous at x

Go back to the [graph](#) of a general distribution function. At a point of positive probability, the probability is the size of the jump. At a smooth point of the graph, the continuous probability density is the slope.

Recall that the existence of a probability density function is not guaranteed for a continuous distribution, but of course the distribution function always makes perfect sense. The advanced section on absolute continuity and density functions has an example of a continuous distribution on the interval $(0, 1)$ that has no probability density function. The distribution function is continuous and strictly increases from 0 to 1 on the interval, but has derivative 0 at almost every point!

Naturally, the distribution function can be defined relative to any of the conditional distributions we have discussed. No new concepts are involved, and all of the results above hold.

Reliability

Suppose again that X is a real-valued random variable with distribution function F . The function in the following definition clearly gives the same information as F .

The function F^c defined by

$$F^c(x) = 1 - F(x) = \mathbb{P}(X > x), \quad x \in \mathbb{R} \quad (3.6.4)$$

is the *right-tail distribution function* of X . Give the mathematical properties of F^c analogous to the properties of F in (2).

Answer

1. F^c is decreasing.
2. $F^c(t) \rightarrow F^c(x)$ as $t \downarrow x$ for $x \in \mathbb{R}$, so F^c is continuous from the right.
3. $F^c(t) \rightarrow \mathbb{P}(X \geq x)$ as $t \uparrow x$ for $x \in \mathbb{R}$, so F^c has left limits.
4. $F^c(x) \rightarrow 0$ as $x \rightarrow \infty$.
5. $F^c(x) \rightarrow 1$ as $x \rightarrow -\infty$.

So F might be called the *left-tail distribution function*. But why have two distribution functions that give essentially the same information? The right-tail distribution function, and related functions, arise naturally in the context of *reliability theory*. For the remainder of this subsection, suppose that T is a random variable with values in $[0, \infty)$ and that T has a continuous distribution with probability density function f . Here are the important definitions:

Suppose that T represents the lifetime of a device.

1. The right tail distribution function F^c is the *reliability function* of T .
2. The function h defined by $h(t) = f(t)/F^c(t)$ for $t \geq 0$ is the *failure rate function* of T .

To interpret the reliability function, note that $F^c(t) = \mathbb{P}(T > t)$ is the probability that the device lasts at least t time units. To interpret the failure rate function, note that if dt is “small” then

$$\mathbb{P}(t < T < t + dt \mid T > t) = \frac{\mathbb{P}(t < T < t + dt)}{\mathbb{P}(T > t)} \approx \frac{f(t) dt}{F^c(t)} = h(t) dt \quad (3.6.5)$$

So $h(t) dt$ is the approximate probability that the device will fail in the interval $(t, t + dt)$, given survival up to time t . Moreover, like the distribution function and the reliability function, the failure rate function also completely determines the distribution of T .

The reliability function can be expressed in terms of the failure rate function by

$$F^c(t) = \exp\left(-\int_0^t h(s) ds\right), \quad t \geq 0 \quad (3.6.6)$$

Proof

At the points of continuity of f we have $\frac{d}{dt} F^c(t) = -f(t)$. Hence

$$\int_0^t h(s) ds = \int_0^t \frac{f(s)}{F^c(s)} ds = \int_0^t -\frac{\frac{d}{ds} F^c(s)}{F^c(s)} ds = -\ln[F^c(t)] \quad (3.6.7)$$

The failure rate function h satisfies the following properties:

1. $h(t) \geq 0$ for $t \geq 0$
2. $\int_0^\infty h(t) dt = \infty$

Proof

1. This follows from the definition.
2. This follows from the [previous result](#) and the fact that $F^c(t) \rightarrow 0$ as $t \rightarrow \infty$.

Conversely, a function that satisfies these properties is the failure rate function for a continuous distribution on $[0, \infty)$:

Suppose that $h : [0, \infty) \rightarrow [0, \infty)$ is piecewise continuous and $\int_0^\infty h(t) dt = \infty$. Then the function G defined by

$$F^c(t) = \exp\left(-\int_0^t h(s) ds\right), \quad t \geq 0 \quad (3.6.8)$$

is a reliability function for a continuous distribution on $[0, \infty)$

Proof

The function F^c is continuous, decreasing, and satisfies $F^c(0) = 1$ and $F^c(t) \rightarrow 0$ as $t \rightarrow \infty$. Hence $F = 1 - F^c$ is the distribution function for a continuous distribution on $[0, \infty)$.

Multivariate Distribution Functions

Suppose now that X and Y are real-valued random variables for an experiment (that is, defined on the same probability space), so that (X, Y) is random vector taking values in a subset of \mathbb{R}^2 .

The *distribution function* of (X, Y) is the function F defined by

$$F(x, y) = \mathbb{P}(X \leq x, Y \leq y), \quad (x, y) \in \mathbb{R}^2 \quad (3.6.9)$$

Figure 3.6.5: $F(x, y)$ is the total probability below and to the left of (x, y) .

In the graph above, the light shading is intended to suggest a continuous distribution of probability, while the darker dots represent points of positive probability. Thus, $F(x, y)$ is the total probability mass below and to the left (that is, southwest) of the point (x, y) . As in the single variable case, the distribution function of (X, Y) completely determines the distribution of (X, Y) .

Suppose that $a, b, c, d \in \mathbb{R}$ with $a < b$ and $c < d$. Then

$$\mathbb{P}(a < X \leq b, c < Y \leq d) = F(b, d) - F(a, d) - F(b, c) + F(a, c) \quad (3.6.10)$$

Proof

Note that $\{X \leq a, Y \leq d\} \cup \{X \leq b, Y \leq c\} \cup \{a < X \leq b, c < Y \leq d\} = \{X \leq b, Y \leq d\}$. The intersection of the first two events is $\{X \leq a, Y \leq c\}$ while the first and third events and the second and third events are disjoint. Thus, from the inclusion-exclusion rule we have

$$F(a, d) + F(b, c) + \mathbb{P}(a < X \leq b, c < Y \leq d) - F(a, c) = F(b, d) \quad (3.6.11)$$

A probability distribution on \mathbb{R}^2 is completely determined by its values on rectangles of the form $(a, b] \times (c, d]$, so just as in the single variable case, it follows that the distribution function of (X, Y) completely determines the distribution of (X, Y) . See the advanced section on existence and uniqueness of positive measures in the chapter on Probability Measures for more details.

In the setting of the previous result, give the appropriate formula on the right for all possible combinations of weak and strong inequalities on the left.

The joint distribution function determines the individual (marginal) distribution functions.

Let F denote the distribution function of (X, Y) , and let G and H denote the distribution functions of X and Y , respectively. Then

1. $G(x) = F(x, \infty)$ for $x \in \mathbb{R}$

2. $H(y) = F(\infty, y)$ for $y \in \mathbb{R}$

Proof

These results follow from the continuity theorem for increasing events. For example, in (a)

$$\mathbb{P}(X \leq x) = \mathbb{P}(X \leq x, Y < \infty) = \lim_{y \rightarrow \infty} \mathbb{P}(X \leq x, Y \leq y) = \lim_{y \rightarrow \infty} F(x, y) \quad (3.6.12)$$

On the other hand, we cannot recover the distribution function of (X, Y) from the individual distribution functions, except when the variables are independent.

Random variables X and Y are independent if and only if

$$F(x, y) = G(x)H(y), \quad (x, y) \in \mathbb{R}^2 \quad (3.6.13)$$

Proof

If X and Y are independent then $F(x, y) = \mathbb{P}(X \leq x, Y \leq y) = \mathbb{P}(X \leq x)\mathbb{P}(Y \leq y) = G(x)H(y)$ for $(x, y) \in \mathbb{R}^2$. Conversely, suppose $F(x, y) = G(x)H(y)$ for $(x, y) \in \mathbb{R}^2$. If $a, b, c, d \in \mathbb{R}$ with $a < b$ and $c < d$ then from (15),

$$\mathbb{P}(a < X \leq b, c < Y \leq d) = G(b)H(d) - G(a)H(d) - G(b)H(c) + G(a)H(c) \quad (3.6.14)$$

$$= [G(b) - G(a)][H(d) - H(c)] = \mathbb{P}(a < X \leq b)\mathbb{P}(c < Y \leq d) \quad (3.6.15)$$

so it follows that X and Y are independent. (Recall again that a probability distribution on \mathbb{R}^2 is completely determined by its values on rectangles.)

All of the results of this subsection generalize in a straightforward way to n -dimensional random vectors. Only the notation is more complicated.

The Empirical Distribution Function

Suppose now that X is a real-valued random variable for a basic random experiment and that we repeat the experiment n times independently. This generates (for the new compound experiment) a sequence of independent variables (X_1, X_2, \dots, X_n) each with the same distribution as X . In statistical terms, this sequence is a *random sample* of size n from the distribution of X . In statistical inference, the observed values (x_1, x_2, \dots, x_n) of the random sample form our *data*.

The *empirical distribution function*, based on the data (x_1, x_2, \dots, x_n) , is defined by

$$F_n(x) = \frac{1}{n} \# \{i \in \{1, 2, \dots, n\} : x_i \leq x\} = \frac{1}{n} \sum_{i=1}^n \mathbf{1}(x_i \leq x), \quad x \in \mathbb{R} \quad (3.6.16)$$

Thus, $F_n(x)$ gives the proportion of values in the data set that are less than or equal to x . The function F_n is a statistical estimator of F , based on the given data set. This concept is explored in more detail in the section on the sample mean in the chapter on Random Samples. In addition, the empirical distribution function is related to the Brownian bridge stochastic process which is studied in the chapter on Brownian motion.

Quantile Functions

Definitions

Suppose again that X is a real-valued random variable with distribution function F .

For $p \in (0, 1)$, a value of x such that $F(x^-) = \mathbb{P}(X < x) \leq p$ and $F(x) = \mathbb{P}(X \leq x) \geq p$ is called a *quantile* of order p for the distribution.

Roughly speaking, a quantile of order p is a value where the graph of the distribution function crosses (or jumps over) p . For example, in the picture below, a is the unique quantile of order p and b is the unique quantile of order q . On the other hand, the quantiles of order r form the interval $[c, d]$, and moreover, d is a quantile for all orders in the interval $[r, s]$. Note also that if X has a continuous distribution (so that F is continuous) and x is a quantile of order $p \in (0, 1)$, then $F(x) = p$.

Figure 3.6.6: Quantiles of various orders

Note that there is an inverse relation of sorts between the quantiles and the cumulative distribution values, but the relation is more complicated than that of a function and its ordinary inverse function, because the distribution function is not one-to-one in general. For many purposes, it is helpful to select a specific quantile for each order; to do this requires defining a *generalized inverse* of the distribution function F .

The *quantile function* F^{-1} of X is defined by

$$F^{-1}(p) = \min\{x \in \mathbb{R} : F(x) \geq p\}, \quad p \in (0, 1) \quad (3.6.17)$$

F^{-1} is well defined

Since F is right continuous and increasing, $\{x \in \mathbb{R} : F(x) \geq p\}$ is an interval of the form $[a, \infty)$. Thus, the minimum of the set is a .

Note that if F strictly increases from 0 to 1 on an interval S (so that the underlying distribution is continuous and is supported on S), then F^{-1} is the ordinary inverse of F . We do not usually define the quantile function at the endpoints 0 and 1. If we did, note that $F^{-1}(0)$ would always be $-\infty$.

Properties

The following exercise justifies the name: $F^{-1}(p)$ is the minimum of the quantiles of order p .

Let $p \in (0, 1)$.

1. $F^{-1}(p)$ is a quantile of order p .
2. If x is a quantile of order p then $F^{-1}(p) \leq x$.

Proof

Let $y = F^{-1}(p)$.

1. Note that $F(y) \geq p$ by definition, and if $x < y$ then $F(x) < p$. Hence $F(y^-) \leq p$. Therefore y is a quantile of order p .
2. Suppose that x is a quantile of order p . Then $F(x) \geq p$ so by definition, $y \leq x$.

Other basic properties of the quantile function are given in the following theorem.

F^{-1} satisfies the following properties:

1. F^{-1} is increasing on $(0, 1)$.
2. $F^{-1}[F(x)] \leq x$ for any $x \in \mathbb{R}$ with $F(x) < 1$.
3. $F[F^{-1}(p)] \geq p$ for any $p \in (0, 1)$.
4. $F^{-1}(p^-) = F^{-1}(p)$ for $p \in (0, 1)$. Thus F^{-1} is continuous from the left.
5. $F^{-1}(p^+) = \inf\{x \in \mathbb{R} : F(x) > p\}$ for $p \in (0, 1)$. Thus F^{-1} has limits from the right.

Proof

1. Note that if $p, q \in (0, 1)$ with $p \leq q$, then $\{x \in \mathbb{R} : F(x) \geq q\} \subseteq \{x \in \mathbb{R} : F(x) \geq p\}$.
2. This follows from the definition: $F^{-1}[F(x)]$ is the smallest $y \in \mathbb{R}$ with $F(y) \geq F(x)$.

3. This also follows from the definition: $F^{-1}(p)$ is a value $y \in \mathbb{R}$ satisfying $F(y) \geq p$.
4. This follows from the fact that F is continuous from the right
5. This follows from the fact that F has limits from the left.

As always, the inverse of a function is obtained essentially by reversing the roles of independent and dependent variables. In the graphs below, note that jumps of F become flat portions of F^{-1} while flat portions of F become jumps of F^{-1} . For $p \in (0, 1)$, the set of quantiles of order p is the closed, bounded interval $[F^{-1}(p), F^{-1}(p^+)]$. Thus, $F^{-1}(p)$ is the smallest quantile of order p , as we noted earlier, while $F^{-1}(p^+)$ is the largest quantile of order p .

Figure 3.6.7: Graph of the distribution function

Figure 3.6.8: Graph of the quantile function

The following basic property will be useful in simulating random variables, a topic explored in the section on transformations of random variables.

For $x \in \mathbb{R}$ and $p \in (0, 1)$, $F^{-1}(p) \leq x$ if and only if $p \leq F(x)$.

Proof

Suppose that $F^{-1}(p) \leq x$. Then, since F is increasing, $F[F^{-1}(p)] \leq F(x)$. But $p \leq F[F^{-1}(p)]$ by part (c) of the previous result, so $p \leq F(x)$. Conversely, suppose that $p \leq F(x)$. Then, since F^{-1} is increasing, $F^{-1}(p) \leq F^{-1}[F(x)]$. But $F^{-1}[F(x)] \leq x$ by part (b) of the previous result, so $F^{-1}(p) \leq x$.

Special Quantiles

Certain quantiles are important enough to deserve special names.

Suppose that X is a real-valued random variable.

1. A quantile of order $\frac{1}{4}$ is a *first quartile* of the distribution.
2. A quantile of order $\frac{1}{2}$ is a *median* or *second quartile* of the distribution.
3. A quantile of order $\frac{3}{4}$ is a *third quartile* of the distribution.

When there is only one median, it is frequently used as a measure of the *center* of the distribution, since it divides the set of values of X in half, by probability. More generally, the quartiles can be used to divide the set of values into fourths, by probability.

Assuming uniqueness, let q_1 , q_2 , and q_3 denote the first, second, and third quartiles of X , respectively, and let $a = F^{-1}(0^+)$ and $b = F^{-1}(1)$.

1. The *interquartile range* is defined to be $q_3 - q_1$.
2. The five parameters (a, q_1, q_2, q_3, b) are referred to as the *five number summary* of the distribution.

Note that the interval $[q_1, q_3]$ roughly gives the middle half of the distribution, so the interquartile range, the length of the interval, is a natural measure of the dispersion of the distribution about the median. Note also that a and b are essentially the minimum and maximum values of X , respectively, although of course, it's possible that $a = -\infty$ or $b = \infty$ (or both). Collectively, the five parameters give a great deal of information about the distribution in terms of the center, spread, and skewness. Graphically, the five numbers are often displayed as a *boxplot* or *box and whisker plot*, which consists of a line extending from the minimum value a to the maximum value b , with a rectangular box from q_1 to q_3 , and “whiskers” at a , the median q_2 , and b . Roughly speaking, the five numbers separate the set of values of X into 4 intervals of approximate probability $\frac{1}{4}$ each.

Figure 3.6.9: The probability density function and boxplot for a continuous distribution

Suppose that X has a continuous distribution that is symmetric about a point $a \in \mathbb{R}$. If $a + t$ is a quantile of order $p \in (0, 1)$ then $a - t$ is a quantile of order $1 - p$.

Proof

Note that this is the quantile function version of [symmetry result](#) for the distribution function. If $a + t$ is a quantile of order p then (since X has a continuous distribution) $F(a + t) = p$. But then $F(a - t) = 1 - F(a + t) = 1 - p$ so $a - t$ is a quantile of order $1 - p$.

Examples and Applications

Distributions of Different Types

Let F be the function defined by

$$F(x) = \begin{cases} 0, & x < 1 \\ \frac{1}{10}, & 1 \leq x < \frac{3}{2} \\ \frac{3}{10}, & \frac{3}{2} \leq x < 2 \\ \frac{6}{10}, & 2 \leq x < \frac{5}{2} \\ \frac{9}{10}, & \frac{5}{2} \leq x < 3 \\ 1, & x \geq 3; \end{cases} \quad (3.6.18)$$

1. Sketch the graph of F and show that F is the distribution function for a discrete distribution.
2. Find the corresponding probability density function f and sketch the graph.
3. Find $\mathbb{P}(2 \leq X < 3)$ where X has this distribution.
4. Find the quantile function and sketch the graph.
5. Find the five number summary and sketch the boxplot.

Answer

1. Note that F increases from 0 to 1, is a step function, and is right continuous.

2. $f(x) = \begin{cases} \frac{1}{10}, & x = 1 \\ \frac{1}{5}, & x = \frac{3}{2} \\ \frac{3}{10}, & x = 2 \\ \frac{3}{10}, & x = \frac{5}{2} \\ \frac{1}{10}, & x = 3 \end{cases}$
3. $\mathbb{P}(2 \leq X < 3) = \frac{3}{5}$
4. $F^{-1}(p) = \begin{cases} 1, & 0 < p \leq \frac{1}{10} \\ \frac{3}{2}, & \frac{1}{10} < p \leq \frac{3}{10} \\ 2, & \frac{3}{10} < p \leq \frac{6}{10} \\ \frac{5}{2}, & \frac{6}{10} < p \leq \frac{9}{10} \\ 3, & \frac{9}{10} < p \leq 1 \end{cases}$
5. $(1, \frac{3}{2}, 2, \frac{5}{2}, 3)$

Let F be the function defined by

$$F(x) = \begin{cases} 0, & x < 0 \\ \frac{x}{x+1}, & x \geq 0 \end{cases} \quad (3.6.19)$$

1. Sketch the graph of F and show that F is the distribution function for a continuous distribution.
2. Find the corresponding probability density function f and sketch the graph.
3. Find $\mathbb{P}(2 \leq X < 3)$ where X has this distribution.
4. Find the quantile function and sketch the graph.
5. Find the five number summary and sketch the boxplot.

Answer

1. Note that F is continuous and increases from 0 to 1.
2. $f(x) = \frac{1}{(x+1)^2}, \quad x > 0$
3. $\mathbb{P}(2 \leq X < 3) = \frac{1}{12}$
4. $F^{-1}(p) = \frac{p}{1-p}, \quad 0 < p < 1$
5. $(0, \frac{1}{3}, 1, 3, \infty)$

The expression $\frac{p}{1-p}$ that occurs in the quantile function in the last exercise is known as the *odds ratio* associated with p , particularly in the context of gambling.

Let F be the function defined by

$$F(x) = \begin{cases} 0, & x < 0 \\ \frac{1}{4}x, & 0 \leq x < 1 \\ \frac{1}{3} + \frac{1}{4}(x-1)^2, & 1 \leq x < 2 \\ \frac{2}{3} + \frac{1}{4}(x-2)^3, & 2 \leq x < 3 \\ 1, & x \geq 3 \end{cases} \quad (3.6.20)$$

1. Sketch the graph of F and show that F is the distribution function of a mixed distribution.
2. Find the partial probability density function of the discrete part and sketch the graph.
3. Find the partial probability density function of the continuous part and sketch the graph.
4. Find $\mathbb{P}(2 \leq X < 3)$ where X has this distribution.
5. Find the quantile function and sketch the graph.
6. Find the five number summary and sketch the boxplot.

Answer

1. Note that F is piece-wise continuous, increases from 0 to 1, and is right continuous.

2. $g(1) = g(2) = g(3) = \frac{1}{12}$
3. $h(x) = \begin{cases} \frac{1}{4}, & 0 < x < 1 \\ \frac{1}{2}(x-1), & 1 < x < 2 \\ \frac{3}{4}(x-2)^2, & 2 < x < 3 \end{cases}$
4. $\mathbb{P}(2 \leq X < 3) = \frac{1}{3}$
5. $F^{-1}(p) = \begin{cases} 4p, & 0 < p \leq \frac{1}{4} \\ 1, & \frac{1}{4} < p \leq \frac{1}{3} \\ 1 + \sqrt{4(p - \frac{1}{3})}, & \frac{1}{3} < p \leq \frac{7}{12} \\ 2, & \frac{7}{12} < p \leq \frac{2}{3} \\ 2 + \sqrt[3]{4(p - \frac{2}{3})}, & \frac{2}{3} < p \leq \frac{11}{12} \\ 3, & \frac{11}{12} < p \leq 1 \end{cases}$
6. $(0, 1, 1 + \sqrt{\frac{2}{3}}, 2 + \sqrt[3]{\frac{1}{3}}, 3)$

The Uniform Distribution

Suppose that X has probability density function $f(x) = \frac{1}{b-a}$ for $x \in [a, b]$, where $a, b \in \mathbb{R}$ and $a < b$.

1. Find the distribution function and sketch the graph.
2. Find the quantile function and sketch the graph.
3. Compute the five-number summary.
4. Sketch the graph of the probability density function with the boxplot on the horizontal axis.

Answer

1. $F(x) = \frac{x-a}{b-a}, \quad a \leq x < b$
2. $F^{-1}(p) = a + (b-a)p, \quad 0 \leq p \leq 1$
3. $(a, \frac{3a+b}{4}, \frac{a+b}{2}, \frac{a+3b}{4}, b)$

The distribution in the last exercise is the *uniform distribution* on the interval $[a, b]$. The left endpoint a is the *location parameter* and the length of the interval $w = b - a$ is the *scale parameter*. The uniform distribution models a point chose “at random” from the interval, and is studied in more detail in the chapter on Special Distributions.

In the special distribution calculator, select the continuous uniform distribution. Vary the location and scale parameters and note the shape of the probability density function and the distribution function.

The Exponential Distribution

Suppose that T has probability density function $f(t) = re^{-rt}$ for $0 \leq t < \infty$, where $r > 0$ is a parameter.

1. Find the distribution function and sketch the graph.
2. Find the reliability function and sketch the graph.
3. Find the failure rate function and sketch the graph.
4. Find the quantile function and sketch the graph.
5. Compute the five-number summary.
6. Sketch the graph of the probability density function with the boxplot on the horizontal axis.

Answer

1. $F(t) = 1 - e^{-rt}, \quad 0 \leq t < \infty$
2. $F^c(t) = e^{-rt}, \quad 0 \leq t < \infty$
3. $h(t) = r, \quad 0 \leq t < \infty$
4. $F^{-1}(p) = -\frac{1}{r} \ln(1-p), \quad 0 \leq p < 1$
5. $(0, \frac{1}{r}[\ln 4 - \ln 3], \frac{1}{r} \ln 2, \frac{1}{r} \ln 4, \infty)$

The distribution in the last exercise is the *exponential distribution* with rate parameter r . Note that this distribution is characterized by the fact that it has *constant failure rate* (and this is the reason for referring to r as the rate parameter). The reciprocal of the rate parameter is the *scale parameter*. The exponential distribution is used to model failure times and other random times under certain conditions, and is studied in detail in the chapter on The Poisson Process.

In the special distribution calculator, select the exponential distribution. Vary the scale parameter b and note the shape of the probability density function and the distribution function.

The Pareto Distribution

Suppose that X has probability density function $f(x) = \frac{a}{x^{a+1}}$ for $1 \leq x < \infty$ where $a > 0$ is a parameter.

1. Find the distribution function.
2. Find the reliability function.
3. Find the failure rate function.
4. Find the quantile function.
5. Compute the five-number summary.
6. In the case $a = 2$, sketch the graph of the probability density function with the boxplot on the horizontal axis.

Answer

1. $F(x) = 1 - \frac{1}{x^a}, \quad 1 \leq x < \infty$
2. $F^c(x) = \frac{1}{x^a}, \quad 1 \leq x < \infty$
3. $h(x) = \frac{a}{x}, \quad 1 \leq x < \infty$
4. $F^{-1}(p) = (1 - p)^{-1/a}, \quad 0 \leq p < 1$
5. $\left(1, \left(\frac{3}{4}\right)^{-1/a}, \left(\frac{1}{2}\right)^{-1/a}, \left(\frac{1}{4}\right)^{-1/a}, \infty\right)$

The distribution in the last exercise is the *Pareto distribution* with shape parameter a , named after Vilfredo Pareto. The Pareto distribution is a heavy-tailed distribution that is sometimes used to model income and certain other economic variables. It is studied in detail in the chapter on Special Distributions.

In the special distribution calculator, select the Pareto distribution. Keep the default value for the scale parameter, but vary the shape parameter and note the shape of the density function and the distribution function.

The Cauchy Distribution

Suppose that X has probability density function $f(x) = \frac{1}{\pi(1+x^2)}$ for $x \in \mathbb{R}$.

1. Find the distribution function and sketch the graph.
2. Find the quantile function and sketch the graph.
3. Compute the five-number summary and the interquartile range.
4. Sketch the graph of the probability density function with the boxplot on the horizontal axis.

Answer

1. $F(x) = \frac{1}{2} + \frac{1}{\pi} \arctan x, \quad x \in \mathbb{R}$
2. $F^{-1}(p) = \tan\left[\pi\left(p - \frac{1}{2}\right)\right], \quad 0 < p < 1$
3. $(-\infty, -1, 0, 1, \infty), \text{IQR} = 2$

The distribution in the last exercise is the *Cauchy distribution*, named after Augustin Cauchy. The Cauchy distribution is studied in more generality in the chapter on Special Distributions.

In the special distribution calculator, select the Cauchy distribution and keep the default parameter values. Note the shape of the density function and the distribution function.

The Weibull Distribution

Let $h(t) = kt^{k-1}$ for $0 < t < \infty$ where $k > 0$ is a parameter.

1. Sketch the graph of h in the cases $0 < k < 1$, $k = 1$, $1 < k < 2$, $k = 2$, and $k > 2$.
2. Show that h is a failure rate function.
3. Find the reliability function and sketch the graph.
4. Find the distribution function and sketch the graph.
5. Find the probability density function and sketch the graph.
6. Find the quantile function and sketch the graph.
7. Compute the five-number summary.

Answer

1. h is decreasing and concave upward if $0 < k < 1$; $h = 1$ (constant) if $k = 1$; h is increasing and concave downward if $1 < k < 2$; $h(t) = t$ (linear) if $k = 2$; h is increasing and concave upward if $k > 2$;
2. $h(t) > 0$ for $0 < t < \infty$ and $\int_0^\infty h(t) dt = \infty$
3. $F^c(t) = \exp(-t^k)$, $0 \leq t < \infty$
4. $F(t) = 1 - \exp(-t^k)$, $0 \leq t < \infty$
5. $f(t) = kt^{k-1} \exp(-t^k)$, $0 \leq t < \infty$
6. $F^{-1}(p) = [-\ln(1-p)]^{1/k}$, $0 \leq p < 1$
7. $(0, [\ln 4 - \ln 3]^{1/k}, [\ln 2]^{1/k}, [\ln 4]^{1/k}, \infty)$

The distribution in the previous exercise is the *Weibull distributions* with shape parameter k , named after Walodi Weibull. The Weibull distribution is studied in detail in the chapter on Special Distributions. Since this family includes increasing, decreasing, and constant failure rates, it is widely used to model the lifetimes of various types of devices.

In the special distribution calculator, select the Weibull distribution. Keep the default scale parameter, but vary the shape parameter and note the shape of the density function and the distribution function.

Beta Distributions

Suppose that X has probability density function $f(x) = 12x^2(1-x)$ for $0 \leq x \leq 1$.

1. Find the distribution function of X and sketch the graph.
2. Find $\mathbb{P}(\frac{1}{4} \leq X \leq \frac{1}{2})$.
3. Compute the five number summary and the interquartile range. You will have to approximate the quantiles.
4. Sketch the graph of the density function with the boxplot on the horizontal axis.

Answer

1. $F(x) = 4x^3 - 3x^4$, $0 \leq x \leq 1$
2. $\mathbb{P}(\frac{1}{4} \leq X \leq \frac{1}{2}) = \frac{67}{256}$
3. $(0, 0.4563, 0.6413, 0.7570, 1)$, IQR = 0.3007

Suppose that X has probability density function $f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$ for $0 < x < 1$.

1. Find the distribution function of X and sketch the graph.
2. Compute $\mathbb{P}(\frac{1}{3} \leq X \leq \frac{2}{3})$.
3. Find the quantile function and sketch the graph.
4. Compute the five number summary and the interquartile range.
5. Sketch the graph of the probability density function with the boxplot on the horizontal axis.

Answer

1. $F(x) = \frac{2}{\pi} \arcsin(\sqrt{x})$, $0 \leq x \leq 1$
2. $\mathbb{P}(\frac{1}{3} \leq X \leq \frac{2}{3}) = 0.2163$
3. $F^{-1}(p) = \sin^2(\frac{\pi p}{2})$, $0 < p < 1$

$$4. \left(0, \frac{1}{2} - \frac{\sqrt{2}}{4}, \frac{1}{2}, \frac{1}{2} + \frac{\sqrt{2}}{4}, 1\right), \text{IQR} = \frac{\sqrt{2}}{2}$$

The distributions in the last two exercises are examples of *beta distributions*. The particular beta distribution in the last exercise is also known as the *arcsine distribution*; the distribution function explains the name. Beta distributions are used to model random proportions and probabilities, and certain other types of random variables, and are studied in detail in the chapter on Special Distributions.

In the special distribution calculator, select the beta distribution. For each of the following parameter values, note the location and shape of the density function and the distribution function.

1. $a = 3, b = 2$. This gives the [first beta distribution](#) above.
2. $a = b = \frac{1}{2}$. This gives the [arcsine distribution](#) above

Logistic Distribution

Let $F(x) = \frac{e^x}{1+e^x}$ for $x \in \mathbb{R}$.

1. Show that F is a distribution function for a continuous distribution, and sketch the graph.
2. Compute $\mathbb{P}(-1 \leq X \leq 1)$ where X is a random variable with distribution function F .
3. Find the quantile function and sketch the graph.
4. Compute the five-number summary and the interquartile range.
5. Find the probability density function and sketch the graph with the boxplot on the horizontal axis.

Answer

1. Note that F is continuous, and increases from 0 to 1.
2. $\mathbb{P}(-1 \leq X \leq 1) = 0.4621$
3. $F^{-1}(p) = \ln\left(\frac{p}{1-p}\right), \quad 0 < p < 1$
4. $(-\infty, -\ln 3, 0, \ln 3, \infty)$
5. $f(x) = \frac{e^x}{(1+e^x)^2}, \quad x \in \mathbb{R}$

The distribution in the last exercise is an *logistic distribution* and the quantile function is known as the *logit function*. The logistic distribution is studied in detail in the chapter on Special Distributions.

In the special distribution calculator, select the logistic distribution and keep the default parameter values. Note the shape of the probability density function and the distribution function.

Extreme Value Distribution

Let $F(x) = e^{-e^{-x}}$ for $x \in \mathbb{R}$.

1. Show that F is a distribution function for a continuous distribution, and sketch the graph.
2. Compute $\mathbb{P}(-1 \leq X \leq 1)$ where X is a random variable with distribution function F .
3. Find the quantile function and sketch the graph.
4. Compute the five-number summary.
5. Find the probability density function and sketch the graph with the boxplot on the horizontal axis.

Answer

1. Note that F is continuous, and increases from 0 to 1.
2. $\mathbb{P}(-1 \leq X \leq 1) = 0.6262$
3. $F^{-1}(p) = -\ln(-\ln p), \quad 0 < p < 1$
4. $(-\infty, -\ln(\ln 4), -\ln(\ln 2), -\ln(\ln 4 - \ln 3), \infty)$
5. $f(x) = e^{-e^{-x}} e^{-x}, \quad x \in \mathbb{R}$

The distribution in the last exercise is the *type 1 extreme value distribution*, also known as the *Gumbel distribution* in honor of Emil Gumbel. Extreme value distributions are studied in detail in the chapter on Special Distributions.

In the special distribution calculator, select the extreme value distribution and keep the default parameter values. Note the shape and location of the probability density function and the distribution function.

The Standard Normal Distribution

Recall that the *standard normal distribution* has probability density function ϕ given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}, \quad z \in \mathbb{R} \quad (3.6.21)$$

This distribution models physical measurements of all sorts subject to small, random errors, and is one of the most important distributions in probability. The normal distribution is studied in more detail in the chapter on Special Distributions. The distribution function Φ , of course, can be expressed as

$$\Phi(z) = \int_{-\infty}^z \phi(x) dx, \quad z \in \mathbb{R} \quad (3.6.22)$$

but Φ and the quantile function Φ^{-1} cannot be expressed, in closed form, in terms of elementary functions. Because of the importance of the normal distribution Φ and Φ^{-1} are themselves considered *special functions*, like \sin , \ln , and many others. Approximate values of these functions can be computed using most mathematical and statistical software packages. Because the distribution is symmetric about 0, $\Phi(-z) = 1 - \Phi(z)$ for $z \in \mathbb{R}$, and equivalently, $\Phi^{-1}(1-p) = -\Phi^{-1}(p)$. In particular, the median is 0.

Open the special distribution calculator and choose the normal distribution. Keep the default parameter values and select CDF view. Note the shape and location of the distribution/quantile function. Compute each of the following:

1. The first and third quartiles
2. The quantiles of order 0.9 and 0.1
3. The quantiles of order 0.95 and 0.05

Miscellaneous Exercises

Suppose that X has probability density function $f(x) = -\ln x$ for $0 < x \leq 1$.

1. Sketch the graph of f .
2. Find the distribution function F and sketch the graph.
3. Find $\mathbb{P}(\frac{1}{3} \leq X \leq \frac{1}{2})$.

Answer

2. $F(x) = x - x \ln x, \quad 0 < x < 1$
3. $\mathbb{P}(\frac{1}{3} \leq X \leq \frac{1}{2}) = \frac{1}{6} + \frac{1}{2} \ln 2 - \frac{1}{3} \ln 3$

Suppose that a pair of fair dice are rolled and the sequence of scores (X_1, X_2) is recorded.

1. Find the distribution function of $Y = X_1 + X_2$, the sum of the scores.
2. Find the distribution function of $V = \max\{X_1, X_2\}$, the maximum score.
3. Find the conditional distribution function of Y given $V = 5$.

Answer

The random variables are discrete, so the CDFs are step functions, with jumps at the values of the variables. The following tables give the values of the CDFs at the values of the random variables.

1.	y	2	3	4	5	6	7	8	9	10	11	12
	$\mathbb{P}(Y \leq y)$	$\frac{1}{36}$	$\frac{3}{36}$	$\frac{6}{36}$	$\frac{10}{36}$	$\frac{15}{36}$	$\frac{21}{36}$	$\frac{26}{36}$	$\frac{30}{36}$	$\frac{33}{36}$	$\frac{35}{36}$	1

2.	v	1	2	3	4	5	6
	$\mathbb{P}(V \leq v)$	$\frac{1}{36}$	$\frac{4}{36}$	$\frac{9}{36}$	$\frac{16}{36}$	$\frac{25}{36}$	1

3.	y	6	7	8	9	10
	$\mathbb{P}(Y \leq y \mid V = 5)$	$\frac{2}{9}$	$\frac{4}{9}$	$\frac{6}{9}$	$\frac{8}{9}$	1

Suppose that (X, Y) has probability density function $f(x, y) = x + y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.

- Find the distribution function of X, Y .
- Compute $\mathbb{P}\left(\frac{1}{4} \leq X \leq \frac{1}{2}, \frac{1}{3} \leq Y \leq \frac{2}{3}\right)$.
- Find the distribution function of X .
- Find the distribution function of Y .
- Find the conditional distribution function of X given $Y = y$ for $0 < y < 1$.
- Find the conditional distribution function of Y given $X = x$ for $0 < x < 1$.
- Are X and Y independent?

Answer

- $F(x, y) = \frac{1}{2}(xy^2 + yx^2); \quad 0 < x < 1, 0 < y < 1$
- $\mathbb{P}\left(\frac{1}{4} \leq X \leq \frac{1}{2}, \frac{1}{3} \leq Y \leq \frac{2}{3}\right) = \frac{7}{96}$
- $G(x) = \frac{1}{2}(x + x^2), \quad 0 < x < 1$
- $H(y) = \frac{1}{2}(y + y^2), \quad 0 < y < 1$
- $G(x \mid y) = \frac{x^2/2 + xy}{y + 1/2}; \quad 0 < x < 1, 0 < y < 1$
- $H(y \mid x) = \frac{y^2/2 + xy}{x + 1/2}; \quad 0 < x < 1, 0 < y < 1$

Statistical Exercises

For the M&M data, compute the empirical distribution function of the total number of candies.

Answer

Let N denote the total number of candies. The empirical distribution function of N is a step function; the following table gives the values of the function at the jump points.

n	50	53	54	55	56	57	58	59	60	61
$\mathbb{P}(N \leq n)$	$\frac{1}{30}$	$\frac{2}{30}$	$\frac{3}{30}$	$\frac{7}{30}$	$\frac{11}{30}$	$\frac{14}{30}$	$\frac{23}{30}$	$\frac{26}{30}$	$\frac{28}{30}$	1

For the cicada data, let BL denotes body length and let G denote gender. Compute the empirical distribution function of the following variables:

- BL
- BL given $G = 1$ (male)
- BL given $G = 0$ (female).
- Do you believe that BL and G are independent?

For statistical versions of some of the topics in this section, see the chapter on Random Samples, and in particular, the sections on empirical distributions and order statistics.

3.7: Transformations of Random Variables

This section studies how the distribution of a random variable changes when the variable is transformed in a deterministic way. If you are a new student of probability, you should skip the technical details.

Basic Theory

The Problem

As usual, we start with a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} is the collection of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . Suppose now that we have a random variable X for the experiment, taking values in a set S , and a function r from S into another set T . Then $Y = r(X)$ is a new random variable taking values in T . If the distribution of X is known, how do we find the distribution of Y ? This is a very basic and important question, and in a superficial sense, the solution is easy. But first recall that for $B \subseteq T$, $r^{-1}(B) = \{x \in S : r(x) \in B\}$ is the inverse image of B under r .

$$\mathbb{P}(Y \in B) = \mathbb{P}[X \in r^{-1}(B)] \quad \text{for } B \subseteq T.$$

Proof

Figure 3.7.1: A function $r : S \rightarrow T$. How is a probability distribution on S transformed by r to a distribution on T ?

However, frequently the distribution of X is known either through its distribution function F or its probability density function f , and we would similarly like to find the distribution function or probability density function of Y . This is a difficult problem in general, because as we will see, even simple transformations of variables with simple distributions can lead to variables with complex distributions. We will solve the problem in various special cases.

Transformed Variables with Discrete Distributions

When the transformed variable Y has a discrete distribution, the probability density function of Y can be computed using basic rules of probability.

Suppose that X has a discrete distribution on a countable set S , with probability density function f . Then Y has a discrete distribution with probability density function g given by

$$g(y) = \sum_{x \in r^{-1}\{y\}} f(x), \quad y \in T \quad (3.7.1)$$

Proof

Figure 3.7.2: A transformation of a discrete probability distribution.

Suppose that X has a continuous distribution on a subset $S \subseteq \mathbb{R}^n$ with probability density function f , and that T is countable. Then Y has a discrete distribution with probability density function g given by

$$g(y) = \int_{r^{-1}\{y\}} f(x) dx, \quad y \in T \quad (3.7.2)$$

Proof

Figure 3.7.3: A continuous distribution on S transformed by a discrete function $r : S \rightarrow T$

So the main problem is often computing the inverse images $r^{-1}\{y\}$ for $y \in T$. The formulas above in the [discrete](#) and [continuous](#) cases are not worth memorizing explicitly; it's usually better to just work each problem from scratch. The main step is to write the event $\{Y = y\}$ in terms of X , and then find the probability of this event using the probability density function of X .

Transformed Variables with Continuous Distributions

Suppose that X has a continuous distribution on a subset $S \subseteq \mathbb{R}^n$ and that $Y = r(X)$ has a continuous distributions on a subset $T \subseteq \mathbb{R}^m$. Suppose also that X has a known probability density function f . In many cases, the probability density function of Y can be found by first finding the distribution function of Y (using basic rules of probability) and then computing the appropriate derivatives of the distribution function. This general method is referred to, appropriately enough, as the *distribution function method*.

Suppose that Y is real valued. The distribution function G of Y is given by

$$G(y) = \int_{r^{-1}(-\infty, y]} f(x) dx, \quad y \in \mathbb{R} \quad (3.7.3)$$

Proof

Again, this follows from the definition of f as a PDF of X . For $y \in \mathbb{R}$,

$$G(y) = \mathbb{P}(Y \leq y) = \mathbb{P}[r(X) \in (-\infty, y]] = \mathbb{P}[X \in r^{-1}(-\infty, y]] = \int_{r^{-1}(-\infty, y]} f(x) dx \quad (3.7.4)$$

As in the discrete case, the formula in (4) not much help, and it's usually better to work each problem from scratch. The main step is to write the event $\{Y \leq y\}$ in terms of X , and then find the probability of this event using the probability density function of X .

The Change of Variables Formula

When the transformation r is one-to-one and smooth, there is a formula for the probability density function of Y directly in terms of the probability density function of X . This is known as the *change of variables* formula. Note that since r is one-to-one, it has an inverse function r^{-1} .

We will explore the one-dimensional case first, where the concepts and formulas are simplest. Thus, suppose that random variable X has a continuous distribution on an interval $S \subseteq \mathbb{R}$, with distribution function F and probability density function f . Suppose that $Y = r(X)$ where r is a differentiable function from S onto an interval T . As usual, we will let G denote the distribution function of Y and g the probability density function of Y .

Suppose that r is strictly increasing on S . For $y \in T$,

1. $G(y) = F[r^{-1}(y)]$
2. $g(y) = f[r^{-1}(y)] \frac{d}{dy} r^{-1}(y)$

Proof

1. $G(y) = \mathbb{P}(Y \leq y) = \mathbb{P}[r(X) \leq y] = \mathbb{P}[X \leq r^{-1}(y)] = F[r^{-1}(y)]$ for $y \in T$. Note that the inequality is preserved since r is increasing.
2. This follows from part (a) by taking derivatives with respect to y and using the chain rule. Recall that $F' = f$.

Suppose that r is strictly decreasing on S . For $y \in T$,

1. $G(y) = 1 - F[r^{-1}(y)]$
2. $g(y) = -f[r^{-1}(y)] \frac{d}{dy} r^{-1}(y)$

Proof

1. $G(y) = \mathbb{P}(Y \leq y) = \mathbb{P}[r(X) \leq y] = \mathbb{P}[X \geq r^{-1}(y)] = 1 - F[r^{-1}(y)]$ for $y \in T$. Note that the inequality is reversed since r is decreasing.
2. This follows from part (a) by taking derivatives with respect to y and using the chain rule. Recall again that $F' = f$.

The formulas for the probability density functions in the [increasing case](#) and the [decreasing case](#) can be combined:

If r is strictly increasing or strictly decreasing on S then the probability density function g of Y is given by

$$g(y) = f[r^{-1}(y)] \left| \frac{d}{dy} r^{-1}(y) \right| \quad (3.7.5)$$

Letting $x = r^{-1}(y)$, the change of variables formula can be written more compactly as

$$g(y) = f(x) \left| \frac{dx}{dy} \right| \quad (3.7.6)$$

Although succinct and easy to remember, the formula is a bit less clear. It must be understood that x on the right should be written in terms of y via the inverse function. The images below give a graphical interpretation of the formula in the two cases where r is increasing and where r is decreasing.

Figure 3.7.4: The change of variables theorems in the increasing and decreasing cases

The generalization of this result from \mathbb{R} to \mathbb{R}^n is basically a theorem in multivariate calculus. First we need some notation. Suppose that r is a one-to-one differentiable function from $S \subseteq \mathbb{R}^n$ onto $T \subseteq \mathbb{R}^n$. The *first derivative* of the inverse function $\mathbf{x} = r^{-1}(\mathbf{y})$ is the $n \times n$ matrix of first partial derivatives:

$$\left(\frac{d\mathbf{x}}{d\mathbf{y}} \right)_{ij} = \frac{\partial x_i}{\partial y_j} \quad (3.7.7)$$

The *Jacobian* (named in honor of Karl Gustav Jacobi) of the inverse function is the determinant of the first derivative matrix

$$\det \left(\frac{d\mathbf{x}}{d\mathbf{y}} \right) \quad (3.7.8)$$

With this compact notation, the multivariate change of variables formula is easy to state.

Suppose that \mathbf{X} is a random variable taking values in $S \subseteq \mathbb{R}^n$, and that \mathbf{X} has a continuous distribution with probability density function f . Suppose also $\mathbf{Y} = r(\mathbf{X})$ where r is a differentiable function from S onto $T \subseteq \mathbb{R}^n$. Then the probability density function g of \mathbf{Y} is given by

$$g(\mathbf{y}) = f(\mathbf{x}) \left| \det \left(\frac{d\mathbf{x}}{d\mathbf{y}} \right) \right|, \quad \mathbf{y} \in T \quad (3.7.9)$$

Proof

The result follows from the multivariate change of variables formula in calculus. If $B \subseteq T$ then

$$\mathbb{P}(\mathbf{Y} \in B) = \mathbb{P}[r(\mathbf{X}) \in B] = \mathbb{P}[\mathbf{X} \in r^{-1}(B)] = \int_{r^{-1}(B)} f(\mathbf{x}) d\mathbf{x} \quad (3.7.10)$$

Using the change of variables $\mathbf{x} = r^{-1}(\mathbf{y})$, $d\mathbf{x} = \left| \det \left(\frac{d\mathbf{x}}{d\mathbf{y}} \right) \right| d\mathbf{y}$ we have

$$\mathbb{P}(\mathbf{Y} \in B) = \int_B f[r^{-1}(\mathbf{y})] \left| \det \left(\frac{d\mathbf{x}}{d\mathbf{y}} \right) \right| d\mathbf{y} \quad (3.7.11)$$

So it follows that g defined in the theorem is a PDF for \mathbf{Y} .

The Jacobian is the infinitesimal scale factor that describes how n -dimensional volume changes under the transformation.

Figure 3.7.5: The multivariate change of variables theorem

Special Transformations

Linear Transformations

Linear transformations (or more technically *affine transformations*) are among the most common and important transformations. Moreover, this type of transformation leads to simple applications of the change of variable theorems. Suppose first that X is a random variable taking values in an interval $S \subseteq \mathbb{R}$ and that X has a continuous distribution on S with probability density function f . Let $Y = a + bX$ where $a \in \mathbb{R}$ and $b \in \mathbb{R} \setminus \{0\}$. Note that Y takes values in $T = \{y = a + bx : x \in S\}$, which is also an interval.

Y has probability density function g given by

$$g(y) = \frac{1}{|b|} f\left(\frac{y-a}{b}\right), \quad y \in T \quad (3.7.12)$$

Proof

The transformation is $y = a + bx$. Hence the inverse transformation is $x = (y - a)/b$ and $dx/dy = 1/b$. The result now follows from the [change of variables theorem](#).

When $b > 0$ (which is often the case in applications), this transformation is known as a *location-scale transformation*; a is the *location parameter* and b is the *scale parameter*. Scale transformations arise naturally when physical units are changed (from feet to meters, for example). Location transformations arise naturally when the physical reference point is changed (measuring time relative to 9:00 AM as opposed to 8:00 AM, for example). The change of temperature measurement from Fahrenheit to Celsius is a location and scale transformation. Location-scale transformations are studied in more detail in the chapter on Special Distributions.

The multivariate version of this result has a simple and elegant form when the linear transformation is expressed in matrix-vector form. Thus suppose that \mathbf{X} is a random variable taking values in $S \subseteq \mathbb{R}^n$ and that \mathbf{X} has a continuous distribution on S with probability density function f . Let $\mathbf{Y} = \mathbf{a} + \mathbf{B}\mathbf{X}$ where $\mathbf{a} \in \mathbb{R}^n$ and \mathbf{B} is an invertible $n \times n$ matrix. Note that \mathbf{Y} takes values in $T = \{\mathbf{a} + \mathbf{B}\mathbf{x} : \mathbf{x} \in S\} \subseteq \mathbb{R}^n$.

\mathbf{Y} has probability density function g given by

$$g(\mathbf{y}) = \frac{1}{|\det(\mathbf{B})|} f[\mathbf{B}^{-1}(\mathbf{y} - \mathbf{a})], \quad \mathbf{y} \in T \quad (3.7.13)$$

Proof

The transformation $\mathbf{y} = \mathbf{a} + \mathbf{B}\mathbf{x}$ maps \mathbb{R}^n one-to-one and onto \mathbb{R}^n . The inverse transformation is $\mathbf{x} = \mathbf{B}^{-1}(\mathbf{y} - \mathbf{a})$. The Jacobian of the inverse transformation is the constant function $\det(\mathbf{B}^{-1}) = 1/\det(\mathbf{B})$. The result now follows from the [multivariate change of variables theorem](#).

Sums and Convolution

Simple addition of random variables is perhaps the most important of all transformations. Suppose that X and Y are random variables on a probability space, taking values in $R \subseteq \mathbb{R}$ and $S \subseteq \mathbb{R}$, respectively, so that (X, Y) takes values in a subset of $R \times S$. Our goal is to find the distribution of $Z = X + Y$. Note that Z takes values in $T = \{z \in \mathbb{R} : z = x + y \text{ for some } x \in R, y \in S\}$. For $z \in T$, let $D_z = \{x \in R : z - x \in S\}$.

Suppose that (X, Y) probability density function f .

1. If (X, Y) has a discrete distribution then $Z = X + Y$ has a discrete distribution with probability density function u given by

$$u(z) = \sum_{x \in D_z} f(x, z - x), \quad z \in T \quad (3.7.14)$$

2. If (X, Y) has a continuous distribution then $Z = X + Y$ has a continuous distribution with probability density function u given by

$$u(z) = \int_{D_z} f(x, z - x) dx, \quad z \in T \quad (3.7.15)$$

Proof

1. $\mathbb{P}(Z = z) = \mathbb{P}(X = x, Y = z - x \text{ for some } x \in D_z) = \sum_{x \in D_z} f(x, z - x)$
2. For $A \subseteq T$, let $C = \{(u, v) \in R \times S : u + v \in A\}$. Then

$$\mathbb{P}(Z \in A) = \mathbb{P}(X + Y \in A) = \int_C f(u, v) d(u, v) \quad (3.7.16)$$

Now use the change of variables $x = u$, $z = u + v$. Then the inverse transformation is $u = x$, $v = z - x$ and the Jacobian is 1. Using the change of variables theorem (8) we have

$$\mathbb{P}(Z \in A) = \int_{D_z \times A} f(x, z - x) d(x, z) = \int_A \int_{D_z} f(x, z - x) dx dz \quad (3.7.17)$$

It follows that Z has probability density function $z \mapsto \int_{D_z} f(x, z - x) dx$.

In the discrete case, R and S are countable, so T is also countable as is D_z for each $z \in T$. In the continuous case, R and S are typically intervals, so T is also an interval as is D_z for $z \in T$. In both cases, determining D_z is often the most difficult step. By far the most important special case occurs when X and Y are independent.

Suppose that X and Y are independent and have probability density functions g and h respectively.

1. If X and Y have discrete distributions then $Z = X + Y$ has a discrete distribution with probability density function $g * h$ given by

$$(g * h)(z) = \sum_{x \in D_z} g(x)h(z - x), \quad z \in T \quad (3.7.18)$$

2. If X and Y have continuous distributions then $Z = X + Y$ has a continuous distribution with probability density function $g * h$ given by

$$(g * h)(z) = \int_{D_z} g(x)h(z - x) dx, \quad z \in T \quad (3.7.19)$$

In both cases, the probability density function $g * h$ is called the *convolution* of g and h .

Proof

Both results follows from the previous result above since $f(x, y) = g(x)h(y)$ is the probability density function of (X, Y) .

As before, determining this set D_z is often the most challenging step in finding the probability density function of Z . However, there is one case where the computations simplify significantly.

Suppose again that X and Y are independent random variables with probability density functions g and h , respectively.

1. In the discrete case, suppose X and Y take values in \mathbb{N} . Then Z has probability density function

$$(g * h)(z) = \sum_{x=0}^z g(x)h(z-x), \quad z \in \mathbb{N} \quad (3.7.20)$$

2. In the continuous case, suppose that X and Y take values in $[0, \infty)$. Then Z has probability density function

$$(g * h)(z) = \int_0^z g(x)h(z-x) dx, \quad z \in [0, \infty) \quad (3.7.21)$$

Proof

1. In this case, $D_z = \{0, 1, \dots, z\}$ for $z \in \mathbb{N}$.
2. In this case, $D_z = [0, z]$ for $z \in [0, \infty)$.

Convolution is a very important mathematical operation that occurs in areas of mathematics outside of probability, and so involving functions that are not necessarily probability density functions. The following result gives some simple properties of convolution.

Convolution (either discrete or continuous) satisfies the following properties, where f , g , and h are probability density functions of the same type.

1. $f * g = g * f$ (the *commutative property*)
2. $(f * g) * h = f * (g * h)$ (the *associative property*)

Proof

An analytic proof is possible, based on the definition of convolution, but a probabilistic proof, based on sums of independent random variables is much better. Thus, suppose that X , Y , and Z are independent random variables with PDFs f , g , and h , respectively.

1. The commutative property of convolution follows from the commutative property of addition: $X + Y = Y + X$.
2. The associative property of convolution follows from the associative property of addition: $(X + Y) + Z = X + (Y + Z)$.

Thus, in part (b) we can write $f * g * h$ without ambiguity. Of course, the constant 0 is the additive identity so $X + 0 = 0 + X = X$ for every random variable X . Also, a constant is independent of every other random variable. It follows that the probability density function δ of 0 (given by $\delta(0) = 1$) is the identity with respect to convolution (at least for discrete PDFs). That is, $f * \delta = \delta * f = f$. The next result is a simple corollary of the [convolution theorem](#), but is important enough to be highlighted.

Suppose that $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of independent and identically distributed real-valued random variables, with common probability density function f . Then $Y_n = X_1 + X_2 + \dots + X_n$ has probability density function $f^{*n} = f * f * \dots * f$, the n -fold *convolution power* of f , for $n \in \mathbb{N}$.

In statistical terms, \mathbf{X} corresponds to *sampling* from the common distribution. By convention, $Y_0 = 0$, so naturally we take $f^{*0} = \delta$. When appropriately scaled and centered, the distribution of Y_n converges to the standard normal distribution as $n \rightarrow \infty$. The precise statement of this result is the *central limit theorem*, one of the fundamental theorems of probability. The central limit theorem is studied in detail in the chapter on Random Samples. Clearly convolution power satisfies the *law of exponents*: $f^{*n} * f^{*m} = f^{*(n+m)}$ for $m, n \in \mathbb{N}$.

Convolution can be generalized to sums of independent variables that are not of the same type, but this generalization is usually done in terms of distribution functions rather than probability density functions.

Products and Quotients

While not as important as sums, products and quotients of real-valued random variables also occur frequently. We will limit our discussion to continuous distributions.

Suppose that (X, Y) has a continuous distribution on \mathbb{R}^2 with probability density function f .

1. Random variable $V = XY$ has probability density function

$$v \mapsto \int_{-\infty}^{\infty} f(x, v/x) \frac{1}{|x|} dx \quad (3.7.22)$$

2. Random variable $W = Y/X$ has probability density function

$$w \mapsto \int_{-\infty}^{\infty} f(x, wx) |x| dx \quad (3.7.23)$$

Proof

We introduce the auxiliary variable $U = X$ so that we have bivariate transformations and can use our [change of variables formula](#).

1. We have the transformation $u = x, v = xy$ and so the inverse transformation is $x = u, y = v/u$. Hence

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{bmatrix} 1 & 0 \\ -v/u^2 & 1/u \end{bmatrix} \quad (3.7.24)$$

and so the Jacobian is $1/u$. Using the change of variables theorem, the joint PDF of (U, V) is $(u, v) \mapsto f(u, v/u) |1/u|$. Hence the PDF of V is

$$v \mapsto \int_{-\infty}^{\infty} f(u, v/u) \frac{1}{|u|} du \quad (3.7.25)$$

2. We have the transformation $u = x, w = y/x$ and so the inverse transformation is $x = u, y = uw$. Hence

$$\frac{\partial(x, y)}{\partial(u, w)} = \begin{bmatrix} 1 & 0 \\ w & u \end{bmatrix} \quad (3.7.26)$$

and so the Jacobian is u . Using the change of variables formula, the joint PDF of (U, W) is $(u, w) \mapsto f(u, uw) |u|$. Hence the PDF of W is

$$w \mapsto \int_{-\infty}^{\infty} f(u, uw) |u| du \quad (3.7.27)$$

If (X, Y) takes values in a subset $D \subseteq \mathbb{R}^2$, then for a given $v \in \mathbb{R}$, the integral in (a) is over $\{x \in \mathbb{R} : (x, v/x) \in D\}$, and for a given $w \in \mathbb{R}$, the integral in (b) is over $\{x \in \mathbb{R} : (x, wx) \in D\}$. As usual, the most important special case of this result is when X and Y are independent.

Suppose that X and Y are independent random variables with continuous distributions on \mathbb{R} having probability density functions g and h , respectively.

1. Random variable $V = XY$ has probability density function

$$v \mapsto \int_{-\infty}^{\infty} g(x) h(v/x) \frac{1}{|x|} dx \quad (3.7.28)$$

2. Random variable $W = Y/X$ has probability density function

$$w \mapsto \int_{-\infty}^{\infty} g(x) h(wx) |x| dx \quad (3.7.29)$$

Proof

These results follow immediately from the previous theorem, since $f(x, y) = g(x)h(y)$ for $(x, y) \in \mathbb{R}^2$.

If X takes values in $S \subseteq \mathbb{R}$ and Y takes values in $T \subseteq \mathbb{R}$, then for a given $v \in \mathbb{R}$, the integral in (a) is over $\{x \in S : v/x \in T\}$, and for a given $w \in \mathbb{R}$, the integral in (b) is over $\{x \in S : wx \in T\}$. As with convolution, determining the domain of integration is often the most challenging step.

Minimum and Maximum

Suppose that (X_1, X_2, \dots, X_n) is a sequence of independent real-valued random variables. The *minimum* and *maximum* transformations

$$U = \min\{X_1, X_2, \dots, X_n\}, \quad V = \max\{X_1, X_2, \dots, X_n\} \quad (3.7.30)$$

are very important in a number of applications. For example, recall that in the standard model of *structural reliability*, a system consists of n components that operate independently. Suppose that X_i represents the lifetime of component $i \in \{1, 2, \dots, n\}$. Then U is the lifetime of the *series system* which operates if and only if each component is operating. Similarly, V is the lifetime of the *parallel system* which operates if and only if at least one component is operating.

A particularly important special case occurs when the random variables are *identically distributed*, in addition to being independent. In this case, the sequence of variables is a *random sample* of size n from the common distribution. The minimum and maximum variables are the extreme examples of *order statistics*. Order statistics are studied in detail in the chapter on Random Samples.

Suppose that (X_1, X_2, \dots, X_n) is a sequence of independent real-valued random variables and that X_i has distribution function F_i for $i \in \{1, 2, \dots, n\}$.

1. $V = \max\{X_1, X_2, \dots, X_n\}$ has distribution function H given by $H(x) = F_1(x)F_2(x) \cdots F_n(x)$ for $x \in \mathbb{R}$.
2. $U = \min\{X_1, X_2, \dots, X_n\}$ has distribution function G given by $G(x) = 1 - [1 - F_1(x)][1 - F_2(x)] \cdots [1 - F_n(x)]$ for $x \in \mathbb{R}$.

Proof

1. Note that since V is the maximum of the variables, $\{V \leq x\} = \{X_1 \leq x, X_2 \leq x, \dots, X_n \leq x\}$. Hence by independence,

$$H(x) = \mathbb{P}(V \leq x) = \mathbb{P}(X_1 \leq x)\mathbb{P}(X_2 \leq x) \cdots \mathbb{P}(X_n \leq x) = F_1(x)F_2(x) \cdots F_n(x), \quad x \in \mathbb{R} \quad (3.7.31)$$

2. Note that since U is the minimum of the variables, $\{U > x\} = \{X_1 > x, X_2 > x, \dots, X_n > x\}$. Hence by independence,

$$\begin{aligned} G(x) &= \mathbb{P}(U > x) = 1 - \mathbb{P}(U \leq x) = 1 - \mathbb{P}(X_1 \leq x)\mathbb{P}(X_2 \leq x) \cdots \mathbb{P}(X_n \leq x) \\ &= 1 - [1 - F_1(x)][1 - F_2(x)] \cdots [1 - F_n(x)], \quad x \in \mathbb{R} \end{aligned}$$

From part (a), note that the product of n distribution functions is another distribution function. From part (b), the product of n right-tail distribution functions is a right-tail distribution function. In the reliability setting, where the random variables are nonnegative, the last statement means that the product of n reliability functions is another reliability function. If X_i has a continuous distribution with probability density function f_i for each $i \in \{1, 2, \dots, n\}$, then U and V also have continuous distributions, and their probability density functions can be obtained by differentiating the distribution functions in parts (a) and (b) of [last theorem](#). The computations are straightforward using the product rule for derivatives, but the results are a bit of a mess.

The formulas in [last theorem](#) are particularly nice when the random variables are identically distributed, in addition to being independent

Suppose that (X_1, X_2, \dots, X_n) is a sequence of independent real-valued random variables, with common distribution function F .

1. $V = \max\{X_1, X_2, \dots, X_n\}$ has distribution function H given by $H(x) = F^n(x)$ for $x \in \mathbb{R}$.
2. $U = \min\{X_1, X_2, \dots, X_n\}$ has distribution function G given by $G(x) = 1 - [1 - F(x)]^n$ for $x \in \mathbb{R}$.

In particular, it follows that a positive integer power of a distribution function is a distribution function. More generally, it's easy to see that every positive power of a distribution function is a distribution function. How could we construct a non-integer power of a distribution function in a probabilistic way?

Suppose that (X_1, X_2, \dots, X_n) is a sequence of independent real-valued random variables, with a common continuous distribution that has probability density function f .

1. $V = \max\{X_1, X_2, \dots, X_n\}$ has probability density function h given by $h(x) = nF^{n-1}(x)f(x)$ for $x \in \mathbb{R}$.
2. $U = \min\{X_1, X_2, \dots, X_n\}$ has probability density function g given by $g(x) = n[1 - F(x)]^{n-1}f(x)$ for $x \in \mathbb{R}$.

Coordinate Systems

For our next discussion, we will consider transformations that correspond to common distance-angle based coordinate systems—polar coordinates in the plane, and cylindrical and spherical coordinates in 3-dimensional space. First, for $(x, y) \in \mathbb{R}^2$, let (r, θ)

denote the standard *polar coordinates* corresponding to the Cartesian coordinates (x, y) , so that $r \in [0, \infty)$ is the *radial distance* and $\theta \in [0, 2\pi)$ is the *polar angle*.

Figure 3.7.6: Polar coordinates. Stover, Christopher and Weisstein, Eric W. "Polar Coordinates." From MathWorld—A Wolfram Web Resource. <http://mathworld.wolfram.com/PolarCoordinates.html>

It's best to give the *inverse transformation*: $x = r \cos \theta$, $y = r \sin \theta$. As we all know from calculus, the Jacobian of the transformation is r . Hence the following result is an immediate consequence of our [change of variables theorem](#):

Suppose that (X, Y) has a continuous distribution on \mathbb{R}^2 with probability density function f , and that (R, Θ) are the polar coordinates of (X, Y) . Then (R, Θ) has probability density function g given by

$$g(r, \theta) = f(r \cos \theta, r \sin \theta)r, \quad (r, \theta) \in [0, \infty) \times [0, 2\pi) \quad (3.7.32)$$

Next, for $(x, y, z) \in \mathbb{R}^3$, let (r, θ, z) denote the standard *cylindrical coordinates*, so that (r, θ) are the standard polar coordinates of (x, y) as above, and coordinate z is left unchanged. Given our previous result, the one for cylindrical coordinates should come as no surprise.

Suppose that (X, Y, Z) has a continuous distribution on \mathbb{R}^3 with probability density function f , and that (R, Θ, Z) are the cylindrical coordinates of (X, Y, Z) . Then (R, Θ, Z) has probability density function g given by

$$g(r, \theta, z) = f(r \cos \theta, r \sin \theta, z)r, \quad (r, \theta, z) \in [0, \infty) \times [0, 2\pi) \times \mathbb{R} \quad (3.7.33)$$

Finally, for $(x, y, z) \in \mathbb{R}^3$, let (r, θ, ϕ) denote the standard *spherical coordinates* corresponding to the Cartesian coordinates (x, y, z) , so that $r \in [0, \infty)$ is the *radial distance*, $\theta \in [0, 2\pi)$ is the *azimuth angle*, and $\phi \in [0, \pi]$ is the *polar angle*. (In spite of our use of the word *standard*, different notations and conventions are used in different subjects.)

Figure 3.7.7: Spherical coordinates, By Dmcq—Own work, CC BY-SA 3.0, [Wikipedia](#)

Once again, it's best to give the *inverse transformation*: $x = r \sin \phi \cos \theta$, $y = r \sin \phi \sin \theta$, $z = r \cos \phi$. As we remember from calculus, the absolute value of the Jacobian is $r^2 \sin \phi$. Hence the following result is an immediate consequence of the change of variables theorem (8):

Suppose that (X, Y, Z) has a continuous distribution on \mathbb{R}^3 with probability density function f , and that (R, Θ, Φ) are the spherical coordinates of (X, Y, Z) . Then (R, Θ, Φ) has probability density function g given by

$$g(r, \theta, \phi) = f(r \sin \phi \cos \theta, r \sin \phi \sin \theta, r \cos \phi)r^2 \sin \phi, \quad (r, \theta, \phi) \in [0, \infty) \times [0, 2\pi) \times [0, \pi] \quad (3.7.34)$$

Sign and Absolute Value

Our next discussion concerns the sign and absolute value of a real-valued random variable.

Suppose that X has a continuous distribution on \mathbb{R} with distribution function F and probability density function f .

1. $|X|$ has distribution function G given by $G(y) = F(y) - F(-y)$ for $y \in [0, \infty)$.
2. $|X|$ has probability density function g given by $g(y) = f(y) + f(-y)$ for $y \in [0, \infty)$.

Proof

1. $\mathbb{P}(|X| \leq y) = \mathbb{P}(-y \leq X \leq y) = F(y) - F(-y)$ for $y \in [0, \infty)$.
2. This follows from part (a) by taking derivatives with respect to y .

Recall that the *sign* function on \mathbb{R} (not to be confused, of course, with the *sine* function) is defined as follows:

$$\text{sgn}(x) = \begin{cases} -1, & x < 0 \\ 0, & x = 0 \\ 1, & x > 0 \end{cases} \quad (3.7.35)$$

Suppose again that X has a continuous distribution on \mathbb{R} with distribution function F and probability density function f , and suppose in addition that the distribution of X is symmetric about 0. Then

1. $|X|$ has distribution function G given by $G(y) = 2F(y) - 1$ for $y \in [0, \infty)$.
2. $|X|$ has probability density function g given by $g(y) = 2f(y)$ for $y \in [0, \infty)$.
3. $\text{sgn}(X)$ is uniformly distributed on $\{-1, 1\}$.
4. $|X|$ and $\text{sgn}(X)$ are independent.

Proof

1. This follows from the previous theorem, since $F(-y) = 1 - F(y)$ for $y > 0$ by symmetry.
2. This follows from part (a) by taking derivatives.
3. Note that $\mathbb{P}[\text{sgn}(X) = 1] = \mathbb{P}(X > 0) = \frac{1}{2}$ and so $\mathbb{P}[\text{sgn}(X) = -1] = \frac{1}{2}$ also.
4. If $A \subseteq (0, \infty)$ then

$$\mathbb{P}[|X| \in A, \text{sgn}(X) = 1] = \mathbb{P}(X \in A) = \int_A f(x) dx = \frac{1}{2} \int_A 2f(x) dx = \mathbb{P}[\text{sgn}(X) = 1] \mathbb{P}(|X| \in A) \quad (3.7.36)$$

Examples and Applications

This subsection contains computational exercises, many of which involve special parametric families of distributions. It is always interesting when a random variable from one parametric family can be transformed into a variable from another family. It is also interesting when a parametric family is *closed* or *invariant* under some transformation on the variables in the family. Often, such properties are what make the parametric families *special* in the first place. Please note these properties when they occur.

Dice

Recall that a *standard die* is an ordinary 6-sided die, with faces labeled from 1 to 6 (usually in the form of dots). A *fair* die is one in which the faces are equally likely. An *ace-six flat die* is a standard die in which faces 1 and 6 occur with probability $\frac{1}{4}$ each and the other faces with probability $\frac{1}{8}$ each.

Suppose that two six-sided dice are rolled and the sequence of scores (X_1, X_2) is recorded. Find the probability density function of $Y = X_1 + X_2$, the sum of the scores, in each of the following cases:

1. Both dice are standard and fair.
2. Both dice are ace-six flat.
3. The first die is standard and fair, and the second is ace-six flat
4. The dice are both fair, but the first die has faces labeled 1, 2, 2, 3, 3, 4 and the second die has faces labeled 1, 3, 4, 5, 6, 8.

Answer

Let $Y = X_1 + X_2$ denote the sum of the scores.

1.	y	2	3	4	5	6	7	8	9	10	11	12
	$\mathbb{P}(Y = y)$	$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$

2.	y	2	3	4	5	6	7	8	9	10	11	12
	$\mathbb{P}(Y = y)$	$\frac{1}{16}$	$\frac{1}{16}$	$\frac{5}{64}$	$\frac{3}{32}$	$\frac{7}{64}$	$\frac{3}{16}$	$\frac{7}{64}$	$\frac{3}{32}$	$\frac{3}{32}$	$\frac{1}{16}$	$\frac{1}{16}$

3.	y	2	3	4	5	6	7	8	9	10	11	12
	$\mathbb{P}(Y = y)$	$\frac{2}{48}$	$\frac{3}{48}$	$\frac{4}{48}$	$\frac{5}{48}$	$\frac{6}{48}$	$\frac{8}{48}$	$\frac{6}{48}$	$\frac{5}{48}$	$\frac{4}{48}$	$\frac{3}{48}$	$\frac{2}{48}$

4. The distribution is the same as for two standard, fair dice in (a).

In the dice experiment, select two dice and select the sum random variable. Run the simulation 1000 times and compare the empirical density function to the probability density function for each of the following cases:

1. fair dice
2. ace-six flat dice

Suppose that n standard, fair dice are rolled. Find the probability density function of the following variables:

1. the minimum score
2. the maximum score.

Answer

Let U denote the minimum score and V the maximum score.

1. $f(u) = \left(1 - \frac{u-1}{6}\right)^n - \left(1 - \frac{u}{6}\right)^n, \quad u \in \{1, 2, 3, 4, 5, 6\}$
2. $g(v) = \left(\frac{v}{6}\right)^n - \left(\frac{v-1}{6}\right)^n, \quad v \in \{1, 2, 3, 4, 5, 6\}$

In the dice experiment, select fair dice and select each of the following random variables. Vary n with the scroll bar and note the shape of the density function. With $n = 4$, run the simulation 1000 times and note the agreement between the empirical density function and the probability density function.

1. minimum score
2. maximum score.

Uniform Distributions

Recall that for $n \in \mathbb{N}_+$, the standard measure of the size of a set $A \subseteq \mathbb{R}^n$ is

$$\lambda_n(A) = \int_A 1 \, dx \quad (3.7.37)$$

In particular, $\lambda_1(A)$ is the length of A for $A \subseteq \mathbb{R}$, $\lambda_2(A)$ is the area of A for $A \subseteq \mathbb{R}^2$, and $\lambda_3(A)$ is the volume of A for $A \subseteq \mathbb{R}^3$. See the technical details in (1) for more advanced information.

Now if $S \subseteq \mathbb{R}^n$ with $0 < \lambda_n(S) < \infty$, recall that the *uniform distribution* on S is the continuous distribution with constant probability density function f defined by $f(x) = 1/\lambda_n(S)$ for $x \in S$. Uniform distributions are studied in more detail in the chapter on Special Distributions.

Let $Y = X^2$. Find the probability density function of Y and sketch the graph in each of the following cases:

1. X is uniformly distributed on the interval $[0, 4]$.
2. X is uniformly distributed on the interval $[-2, 2]$.
3. X is uniformly distributed on the interval $[-1, 3]$.

Answer

1. $g(y) = \frac{1}{8\sqrt{y}}, \quad 0 < y < 16$
2. $g(y) = \frac{1}{4\sqrt{y}}, \quad 0 < y < 4$
3. $g(y) = \begin{cases} \frac{1}{4\sqrt{y}}, & 0 < y < 1 \\ \frac{1}{8\sqrt{y}}, & 1 < y < 9 \end{cases}$

Compare the distributions in the last exercise. In part (c), note that even a simple transformation of a simple distribution can produce a complicated distribution. In this particular case, the complexity is caused by the fact that $x \mapsto x^2$ is one-to-one on part of the domain $\{0\} \cup (1, 3]$ and two-to-one on the other part $[-1, 1] \setminus \{0\}$.

On the other hand, the uniform distribution is preserved under a linear transformation of the random variable.

Suppose that \mathbf{X} has the continuous uniform distribution on $S \subseteq \mathbb{R}^n$. Let $\mathbf{Y} = \mathbf{a} + \mathbf{B}\mathbf{X}$, where $\mathbf{a} \in \mathbb{R}^n$ and \mathbf{B} is an invertible $n \times n$ matrix. Then \mathbf{Y} is uniformly distributed on $T = \{\mathbf{a} + \mathbf{B}\mathbf{x} : \mathbf{x} \in S\}$.

Proof

This follows directly from the general result on linear transformations in (10). Note that the PDF g of \mathbf{Y} is constant on T .

For the following three exercises, recall that the *standard uniform distribution* is the uniform distribution on the interval $[0, 1]$.

Suppose that X and Y are independent and that each has the standard uniform distribution. Let $U = X + Y$, $V = X - Y$, $W = XY$, $Z = Y/X$. Find the probability density function of each of the follow:

1. (U, V)
2. U
3. V
4. W
5. Z

Answer

1. $g(u, v) = \frac{1}{2}$ for (u, v) in the square region $T \subset \mathbb{R}^2$ with vertices $\{(0, 0), (1, 1), (2, 0), (1, -1)\}$ So (U, V) is uniformly distributed on T .
2. $g_1(u) = \begin{cases} u, & 0 < u < 1 \\ 2 - u, & 1 < u < 2 \end{cases}$
3. $g_2(v) = \begin{cases} 1 - v, & 0 < v < 1 \\ 1 + v, & -1 < v < 0 \end{cases}$
4. $h_1(w) = -\ln w$ for $0 < w \leq 1$
5. $h_2(z) = \begin{cases} \frac{1}{2}, & 0 \leq z \leq 1 \\ \frac{1}{2z^2}, & 1 \leq z < \infty \end{cases}$

Suppose that X , Y , and Z are independent, and that each has the standard uniform distribution. Find the probability density function of $(U, V, W) = (X + Y, Y + Z, X + Z)$.

Answer

$g(u, v, w) = \frac{1}{2}$ for (u, v, w) in the rectangular region $T \subset \mathbb{R}^3$ with vertices $\{(0, 0, 0), (1, 0, 1), (1, 1, 0), (0, 1, 1), (2, 1, 1), (1, 1, 2), (1, 2, 1), (2, 2, 2)\}$ So (U, V, W) is uniformly distributed on T .

Suppose that (X_1, X_2, \dots, X_n) is a sequence of independent random variables, each with the standard uniform distribution. Find the distribution function and probability density function of the following variables.

1. $U = \min\{X_1, X_2, \dots, X_n\}$
2. $V = \max\{X_1, X_2, \dots, X_n\}$

Answer

1. $G(t) = 1 - (1 - t)^n$ and $g(t) = n(1 - t)^{n-1}$, both for $t \in [0, 1]$
2. $H(t) = t^n$ and $h(t) = nt^{n-1}$, both for $t \in [0, 1]$

Both distributions in the last exercise are *beta distributions*. More generally, all of the order statistics from a random sample of standard uniform variables have beta distributions, one of the reasons for the importance of this family of distributions. Beta distributions are studied in more detail in the chapter on Special Distributions.

In the order statistic experiment, select the uniform distribution.

1. Set $k = 1$ (this gives the minimum U). Vary n with the scroll bar and note the shape of the probability density function. With $n = 5$, run the simulation 1000 times and note the agreement between the empirical density function and the true probability density function.
2. Vary n with the scroll bar, set $k = n$ each time (this gives the maximum V), and note the shape of the probability density function. With $n = 5$ run the simulation 1000 times and compare the empirical density function and the probability density function.

Let f denote the probability density function of the standard uniform distribution.

1. Compute f^{*2}
2. Compute f^{*3}
3. Graph f , f^{*2} , and f^{*3} on the same set of axes.

Answer

$$1. f^{*2}(z) = \begin{cases} z, & 0 < z < 1 \\ 2 - z, & 1 < z < 2 \end{cases}$$

$$2. f^{*3}(z) = \begin{cases} \frac{1}{2}z^2, & 0 < z < 1 \\ 1 - \frac{1}{2}(z-1)^2 - \frac{1}{2}(2-z)^2, & 1 < z < 2 \\ \frac{1}{2}(3-z)^2, & 2 < z < 3 \end{cases}$$

In the last exercise, you can see the behavior predicted by the central limit theorem beginning to emerge. Recall that if (X_1, X_2, X_3) is a sequence of independent random variables, each with the standard uniform distribution, then f , f^{*2} , and f^{*3} are the probability density functions of X_1 , $X_1 + X_2$, and $X_1 + X_2 + X_3$, respectively. More generally, if (X_1, X_2, \dots, X_n) is a sequence of independent random variables, each with the standard uniform distribution, then the distribution of $\sum_{i=1}^n X_i$ (which has probability density function f^{*n}) is known as the *Irwin-Hall* distribution with parameter n . The Irwin-Hall distributions are studied in more detail in the chapter on Special Distributions.

Open the Special Distribution Simulator and select the Irwin-Hall distribution. Vary the parameter n from 1 to 3 and note the shape of the probability density function. (These are the density functions in the previous exercise). For each value of n , run the simulation 1000 times and compare the empirical density function and the probability density function.

Simulations

A remarkable fact is that the standard uniform distribution can be transformed into almost any other distribution on \mathbb{R} . This is particularly important for simulations, since many computer languages have an algorithm for generating *random numbers*, which are simulations of independent variables, each with the standard uniform distribution. Conversely, any continuous distribution supported on an interval of \mathbb{R} can be transformed into the standard uniform distribution.

Suppose first that F is a distribution function for a distribution on \mathbb{R} (which may be discrete, continuous, or mixed), and let F^{-1} denote the quantile function.

Suppose that U has the standard uniform distribution. Then $X = F^{-1}(U)$ has distribution function F .

Proof

The critical property satisfied by the quantile function (regardless of the type of distribution) is $F^{-1}(p) \leq x$ if and only if $p \leq F(x)$ for $p \in (0, 1)$ and $x \in \mathbb{R}$. Hence for $x \in \mathbb{R}$, $\mathbb{P}(X \leq x) = \mathbb{P}[F^{-1}(U) \leq x] = \mathbb{P}[U \leq F(x)] = F(x)$.

Assuming that we can compute F^{-1} , the previous exercise shows how we can simulate a distribution with distribution function F . To rephrase the result, we can simulate a variable with distribution function F by simply computing a *random quantile*. Most of the apps in this project use this method of simulation. The first image below shows the graph of the distribution function of a rather complicated mixed distribution, represented in blue on the horizontal axis. In the second image, note how the uniform distribution on $[0, 1]$, represented by the thick red line, is transformed, via the quantile function, into the given distribution.

Figure 3.7.8: The random quantile method of simulation

There is a partial converse to the previous result, for continuous distributions.

Suppose that X has a continuous distribution on an interval $S \subseteq \mathbb{R}$. Then $U = F(X)$ has the standard uniform distribution.

Proof

For $u \in (0, 1)$ recall that $F^{-1}(u)$ is a quantile of order u . Since X has a continuous distribution,

$$\mathbb{P}(U \geq u) = \mathbb{P}[F(X) \geq u] = \mathbb{P}[X \geq F^{-1}(u)] = 1 - F[F^{-1}(u)] = 1 - u \quad (3.7.38)$$

Hence U is uniformly distributed on $(0, 1)$.

Show how to simulate the uniform distribution on the interval $[a, b]$ with a random number. Using your calculator, simulate 5 values from the uniform distribution on the interval $[2, 10]$.

Answer

$X = a + U(b - a)$ where U is a random number.

Beta Distributions

Suppose that X has the probability density function f given by $f(x) = 3x^2$ for $0 \leq x \leq 1$. Find the probability density function of each of the following:

1. $U = X^2$
2. $V = \sqrt{X}$
3. $W = \frac{1}{X}$

Proof

1. $g(u) = \frac{3}{2}u^{1/2}$, for $0 < u \leq 1$
2. $h(v) = 6v^5$ for $0 \leq v \leq 1$
3. $k(w) = \frac{3}{w^4}$ for $1 \leq w < \infty$

Random variables X , U , and V in the previous exercise have *beta distributions*, the same family of distributions that we saw in the exercise [above](#) for the minimum and maximum of independent standard uniform variables. In general, beta distributions are widely used to model random proportions and probabilities, as well as physical quantities that take values in closed bounded intervals (which after a change of units can be taken to be $[0, 1]$). On the other hand, W has a Pareto distribution, named for Vilfredo Pareto. The family of beta distributions and the family of Pareto distributions are studied in more detail in the chapter on Special Distributions.

Suppose that the radius R of a sphere has a beta distribution probability density function f given by $f(r) = 12r^2(1 - r)$ for $0 \leq r \leq 1$. Find the probability density function of each of the following:

1. The circumference $C = 2\pi R$
2. The surface area $A = 4\pi R^2$
3. The volume $V = \frac{4}{3}\pi R^3$

Answer

1. $g(c) = \frac{3}{4\pi^4} c^2 (2\pi - c)$ for $0 \leq c \leq 2\pi$
2. $h(a) = \frac{3}{8\pi^2} \sqrt{a} (2\sqrt{\pi} - \sqrt{a})$ for $0 \leq a \leq 4\pi$
3. $k(v) = \frac{3}{\pi} \left[1 - \left(\frac{3}{4\pi} \right)^{1/3} v^{1/3} \right]$ for $0 \leq v \leq \frac{4}{3}\pi$

Suppose that the grades on a test are described by the random variable $Y = 100X$ where X has the beta distribution with probability density function f given by $f(x) = 12x(1-x)^2$ for $0 \leq x \leq 1$. The grades are generally low, so the teacher decides to “curve” the grades using the transformation $Z = 10\sqrt{Y} = 100\sqrt{X}$. Find the probability density function of

1. Y
2. Z

Answer

1. $g(y) = \frac{3}{25} \left(\frac{y}{100} \right) \left(1 - \frac{y}{100} \right)^2$ for $0 \leq y \leq 100$.
2. $h(z) = \frac{3}{1250} z \left(\frac{z^2}{10\,000} \right) \left(1 - \frac{z^2}{10\,000} \right)^2$ for $0 \leq z \leq 100$

Bernoulli Trials

Recall that a *Bernoulli trials sequence* is a sequence (X_1, X_2, \dots) of independent, identically distributed indicator random variables. In the usual terminology of reliability theory, $X_i = 0$ means *failure* on trial i , while $X_i = 1$ means *success* on trial i . The basic parameter of the process is the probability of success $p = \mathbb{P}(X_i = 1)$, so $p \in [0, 1]$. The random process is named for Jacob Bernoulli and is studied in detail in the chapter on Bernoulli trials.

For $i \in \mathbb{N}_+$, the probability density function f of the trial variable X_i is $f(x) = p^x(1-p)^{1-x}$ for $x \in \{0, 1\}$.

Proof

By definition, $f(0) = 1 - p$ and $f(1) = p$. These can be combined succinctly with the formula $f(x) = p^x(1-p)^{1-x}$ for $x \in \{0, 1\}$.

Now let Y_n denote the number of successes in the first n trials, so that $Y_n = \sum_{i=1}^n X_i$ for $n \in \mathbb{N}$.

Y_n has the probability density function f_n given by

$$f_n(y) = \binom{n}{y} p^y (1-p)^{n-y}, \quad y \in \{0, 1, \dots, n\} \quad (3.7.39)$$

Proof

We have seen this derivation before. The number of bit strings of length n with 1 occurring exactly y times is $\binom{n}{y}$ for $y \in \{0, 1, \dots, n\}$. By the Bernoulli trials assumptions, the probability of each such bit string is $p^y(1-p)^{n-y}$.

The distribution of Y_n is the *binomial distribution* with parameters n and p . The binomial distribution is studied in more detail in the chapter on Bernoulli trials

For $m, n \in \mathbb{N}$

1. $f_n = f^{*n}$.
2. $f_m * f_n = f_{m+n}$.

Proof

Part (a) can be proved directly from the definition of convolution, but the result also follows simply from the fact that $Y_n = X_1 + X_2 + \dots + X_n$.

From part (b) it follows that if Y and Z are independent variables, and that Y has the binomial distribution with parameters $n \in \mathbb{N}$ and $p \in [0, 1]$ while Z has the binomial distribution with parameter $m \in \mathbb{N}$ and p , then $Y + Z$ has the binomial distribution with parameter $m + n$ and p .

Find the probability density function of the difference between the number of successes and the number of failures in $n \in \mathbb{N}$ Bernoulli trials with success parameter $p \in [0, 1]$

Answer

$$f(k) = \binom{n}{(n+k)/2} p^{(n+k)/2} (1-p)^{(n-k)/2} \text{ for } k \in \{-n, -n+2, \dots, n-2, n\}$$

The Poisson Distribution

Recall that the *Poisson distribution* with parameter $t \in (0, \infty)$ has probability density function f given by

$$f_t(n) = e^{-t} \frac{t^n}{n!}, \quad n \in \mathbb{N} \quad (3.7.40)$$

This distribution is named for Simeon Poisson and is widely used to model the number of random points in a region of time or space; the parameter t is proportional to the size of the region. The Poisson distribution is studied in detail in the chapter on The Poisson Process.

If $a, b \in (0, \infty)$ then $f_a * f_b = f_{a+b}$.

Proof

Let $z \in \mathbb{N}$. Using the definition of convolution and the binomial theorem we have

$$(f_a * f_b)(z) = \sum_{x=0}^z f_a(x) f_b(z-x) = \sum_{x=0}^z e^{-a} \frac{a^x}{x!} e^{-b} \frac{b^{z-x}}{(z-x)!} = e^{-(a+b)} \frac{1}{z!} \sum_{x=0}^z \frac{z!}{x!(z-x)!} a^x b^{z-x} \quad (3.7.41)$$

$$= e^{-(a+b)} \frac{1}{z!} \sum_{x=0}^z \binom{z}{x} a^x b^{z-x} = e^{-(a+b)} \frac{(a+b)^z}{z!} = f_{a+b}(z) \quad (3.7.42)$$

The last result means that if X and Y are independent variables, and X has the Poisson distribution with parameter $a > 0$ while Y has the Poisson distribution with parameter $b > 0$, then $X + Y$ has the Poisson distribution with parameter $a + b$. In terms of the Poisson model, X could represent the number of points in a region A and Y the number of points in a region B (of the appropriate sizes so that the parameters are a and b respectively). The independence of X and Y corresponds to the regions A and B being disjoint. Then $X + Y$ is the number of points in $A \cup B$.

The Exponential Distribution

Recall that the *exponential distribution* with rate parameter $r \in (0, \infty)$ has probability density function f given by $f(t) = re^{-rt}$ for $t \in [0, \infty)$. This distribution is often used to model random times such as failure times and lifetimes. In particular, the times between arrivals in the Poisson model of random points in time have independent, identically distributed exponential distributions. The Exponential distribution is studied in more detail in the chapter on Poisson Processes.

Show how to simulate, with a random number, the exponential distribution with rate parameter r . Using your calculator, simulate 5 values from the exponential distribution with parameter $r = 3$.

Answer

$$X = -\frac{1}{r} \ln(1 - U) \text{ where } U \text{ is a random number. Since } 1 - U \text{ is also a random number, a simpler solution is } X = -\frac{1}{r} \ln U.$$

For the next exercise, recall that the *floor* and *ceiling* functions on \mathbb{R} are defined by

$$\lfloor x \rfloor = \max\{n \in \mathbb{Z} : n \leq x\}, \quad \lceil x \rceil = \min\{n \in \mathbb{Z} : n \geq x\}, \quad x \in \mathbb{R} \quad (3.7.43)$$

Suppose that T has the exponential distribution with rate parameter $r \in (0, \infty)$. Find the probability density function of each of the following random variables:

1. $Y = \lfloor T \rfloor$
2. $Z = \lceil T \rceil$

Answer

1. $\mathbb{P}(Y = n) = e^{-rn} (1 - e^{-r}) \text{ for } n \in \mathbb{N}$
2. $\mathbb{P}(Z = n) = e^{-r(n-1)} (1 - e^{-r}) \text{ for } n \in \mathbb{N}$

Note that the distributions in the previous exercise are geometric distributions on \mathbb{N} and on \mathbb{N}_+ , respectively. In many respects, the geometric distribution is a discrete version of the exponential distribution.

Suppose that T has the exponential distribution with rate parameter $r \in (0, \infty)$. Find the probability density function of each of the following random variables:

1. $X = T^2$
2. $Y = e^T$
3. $Z = \ln T$

Answer

1. $g(x) = re^{-r\sqrt{x}} / 2\sqrt{x}$ for $0 < x < \infty$
2. $h(y) = ry^{-(r+1)}$ for $1 < y < \infty$
3. $k(z) = r \exp(-re^z)e^z$ for $z \in \mathbb{R}$

In the previous exercise, Y has a Pareto distribution while Z has an extreme value distribution. Both of these are studied in more detail in the chapter on Special Distributions.

Suppose that X and Y are independent random variables, each having the exponential distribution with parameter 1. Let $Z = \frac{Y}{X}$.

1. Find the distribution function of Z .
2. Find the probability density function of Z .

Answer

1. $G(z) = 1 - \frac{1}{1+z}$, $0 < z < \infty$
2. $g(z) = \frac{1}{(1+z)^2}$, $0 < z < \infty$

Suppose that X has the exponential distribution with rate parameter $a > 0$, Y has the exponential distribution with rate parameter $b > 0$, and that X and Y are independent. Find the probability density function of $Z = X + Y$ in each of the following cases.

1. $a = b$
2. $a \neq b$

Answer

1. $h(z) = a^2 ze^{-az}$ for $0 < z < \infty$
2. $h(z) = \frac{ab}{b-a} (e^{-az} - e^{-bz})$ for $0 < z < \infty$

Suppose that (T_1, T_2, \dots, T_n) is a sequence of independent random variables, and that T_i has the exponential distribution with rate parameter $r_i > 0$ for each $i \in \{1, 2, \dots, n\}$.

1. Find the probability density function of $U = \min\{T_1, T_2, \dots, T_n\}$.
2. Find the distribution function of $V = \max\{T_1, T_2, \dots, T_n\}$.
3. Find the probability density function of V in the special case that $r_i = r$ for each $i \in \{1, 2, \dots, n\}$.

Answer

1. $g(t) = ae^{-at}$ for $0 \leq t < \infty$ where $a = r_1 + r_2 + \dots + r_n$
2. $H(t) = (1 - e^{-r_1 t})(1 - e^{-r_2 t}) \dots (1 - e^{-r_n t})$ for $0 \leq t < \infty$
3. $h(t) = nre^{-rt}(1 - e^{-rt})^{n-1}$ for $0 \leq t < \infty$

Note that the minimum U in part (a) has the exponential distribution with parameter $r_1 + r_2 + \dots + r_n$. In particular, suppose that a series system has independent components, each with an exponentially distributed lifetime. Then the lifetime of the system is also exponentially distributed, and the failure rate of the system is the sum of the component failure rates.

In the order statistic experiment, select the exponential distribution.

1. Set $k = 1$ (this gives the minimum U). Vary n with the scroll bar and note the shape of the probability density function. With $n = 5$, run the simulation 1000 times and compare the empirical density function and the probability density function.
2. Vary n with the scroll bar and set $k = n$ each time (this gives the maximum V). Note the shape of the density function. With $n = 5$, run the simulation 1000 times and compare the empirical density function and the probability density function.

Suppose again that (T_1, T_2, \dots, T_n) is a sequence of independent random variables, and that T_i has the exponential distribution with rate parameter $r_i > 0$ for each $i \in \{1, 2, \dots, n\}$. Then

$$\mathbb{P}(T_i < T_j \text{ for all } j \neq i) = \frac{r_i}{\sum_{j=1}^n r_j} \quad (3.7.44)$$

Proof

When $n = 2$, the result was shown in the section on joint distributions. Returning to the case of general n , note that $T_i < T_j$ for all $j \neq i$ if and only if $T_i < \min\{T_j : j \neq i\}$. Note that the minimum on the right is independent of T_i and by the [result above](#), has an exponential distribution with parameter $\sum_{j \neq i} r_j$.

The result in the previous exercise is very important in the theory of continuous-time Markov chains. If we have a bunch of independent alarm clocks, with exponentially distributed alarm times, then the probability that clock i is the first one to sound is $r_i / \sum_{j=1}^n r_j$.

The Gamma Distribution

Recall that the (standard) *gamma distribution* with shape parameter $n \in \mathbb{N}_+$ has probability density function

$$g_n(t) = e^{-t} \frac{t^{n-1}}{(n-1)!}, \quad 0 \leq t < \infty \quad (3.7.45)$$

With a positive integer shape parameter, as we have here, it is also referred to as the *Erlang distribution*, named for Agner Erlang. This distribution is widely used to model random times under certain basic assumptions. In particular, the n th arrival times in the Poisson model of random points in time has the gamma distribution with parameter n . The Erlang distribution is studied in more detail in the chapter on the Poisson Process, and in greater generality, the gamma distribution is studied in the chapter on Special Distributions.

Let $g = g_1$, and note that this is the probability density function of the exponential distribution with parameter 1, which was the topic of our last discussion.

If $m, n \in \mathbb{N}_+$ then

1. $g_n = g^{*n}$
2. $g_m * g_n = g_{m+n}$

Proof

Part (a) hold trivially when $n = 1$. Also, for $t \in [0, \infty)$,

$$g_n * g(t) = \int_0^t g_n(s)g(t-s) ds = \int_0^t e^{-s} \frac{s^{n-1}}{(n-1)!} e^{-(t-s)} ds = e^{-t} \int_0^t \frac{s^{n-1}}{(n-1)!} ds = e^{-t} \frac{t^n}{n!} = g_{n+1}(t) \quad (3.7.46)$$

Part (b) follows from (a).

Part (b) means that if X has the gamma distribution with shape parameter m and Y has the gamma distribution with shape parameter n , and if X and Y are independent, then $X + Y$ has the gamma distribution with shape parameter $m + n$. In the context of the Poisson model, part (a) means that the n th arrival time is the sum of the n independent interarrival times, which have a common exponential distribution.

Suppose that T has the gamma distribution with shape parameter $n \in \mathbb{N}_+$. Find the probability density function of $X = \ln T$.

Answer

$$h(x) = \frac{1}{(n-1)!} \exp(-e^x) e^{nx} \text{ for } x \in \mathbb{R}$$

The Pareto Distribution

Recall that the *Pareto distribution* with shape parameter $a \in (0, \infty)$ has probability density function f given by

$$f(x) = \frac{a}{x^{a+1}}, \quad 1 \leq x < \infty \quad (3.7.47)$$

Members of this family have already come up in several of the previous exercises. The Pareto distribution, named for Vilfredo Pareto, is a heavy-tailed distribution often used for modeling income and other financial variables. The Pareto distribution is studied in more detail in the chapter on Special Distributions.

Suppose that X has the Pareto distribution with shape parameter a . Find the probability density function of each of the following random variables:

1. $U = X^2$
2. $V = \frac{1}{X}$
3. $Y = \ln X$

Answer

1. $g(u) = \frac{a/2}{u^{a/2+1}}$ for $1 \leq u < \infty$
2. $h(v) = av^{a-1}$ for $0 < v < 1$
3. $k(y) = ae^{-ay}$ for $0 \leq y < \infty$

In the previous exercise, V also has a Pareto distribution but with parameter $\frac{a}{2}$; Y has the beta distribution with parameters a and $b = 1$; and Z has the exponential distribution with rate parameter a .

Show how to simulate, with a random number, the Pareto distribution with shape parameter a . Using your calculator, simulate 5 values from the Pareto distribution with shape parameter $a = 2$.

Answer

Using the [random quantile method](#), $X = \frac{1}{(1-U)^{1/a}}$ where U is a random number. More simply, $X = \frac{1}{U^{1/a}}$, since $1 - U$ is also a random number.

The Normal Distribution

Recall that the *standard normal distribution* has probability density function ϕ given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}, \quad z \in \mathbb{R} \quad (3.7.48)$$

Suppose that Z has the standard normal distribution, and that $\mu \in (-\infty, \infty)$ and $\sigma \in (0, \infty)$.

1. Find the probability density function f of $X = \mu + \sigma Z$
2. Sketch the graph of f , noting the important qualitative features.

Answer

1. $f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right]$ for $x \in \mathbb{R}$
2. f is symmetric about $x = \mu$. f increases and then decreases, with mode $x = \mu$. f is concave upward, then downward, then upward again, with inflection points at $x = \mu \pm \sigma$. $f(x) \rightarrow 0$ as $x \rightarrow \infty$ and as $x \rightarrow -\infty$

Random variable X has the *normal distribution* with *location parameter* μ and *scale parameter* σ . The normal distribution is perhaps the most important distribution in probability and mathematical statistics, primarily because of the central limit theorem, one of the fundamental theorems. It is widely used to model physical measurements of all types that are subject to small, random errors. The normal distribution is studied in detail in the chapter on Special Distributions.

Suppose that Z has the standard normal distribution. Find the probability density function of Z^2 and sketch the graph.

Answer

$$g(v) = \frac{1}{\sqrt{2\pi v}} e^{-\frac{1}{2}v} \text{ for } 0 < v < \infty$$

Random variable V has the *chi-square distribution* with 1 degree of freedom. Chi-square distributions are studied in detail in the chapter on Special Distributions.

Suppose that X and Y are independent random variables, each with the standard normal distribution, and let (R, Θ) be the standard polar coordinates (X, Y) . Find the probability density function of

1. (R, Θ)
2. R
3. Θ

Answer

Note that the joint PDF of (X, Y) is

$$f(x, y) = \phi(x)\phi(y) = \frac{1}{2\pi} e^{-\frac{1}{2}(x^2+y^2)}, \quad (x, y) \in \mathbb{R}^2 \quad (3.7.49)$$

From the result above [polar coordinates](#), the PDF of (R, Θ) is

$$g(r, \theta) = f(r \cos \theta, r \sin \theta) r = \frac{1}{2\pi} r e^{-\frac{1}{2}r^2}, \quad (r, \theta) \in [0, \infty) \times [0, 2\pi) \quad (3.7.50)$$

From the factorization theorem for joint PDFs, it follows that R has probability density function $h(r) = r e^{-\frac{1}{2}r^2}$ for $0 \leq r < \infty$, Θ is uniformly distributed on $[0, 2\pi)$, and that R and Θ are independent.

The distribution of R is the (standard) *Rayleigh distribution*, and is named for John William Strutt, Lord Rayleigh. The Rayleigh distribution is studied in more detail in the chapter on Special Distributions.

The standard normal distribution does not have a simple, closed form quantile function, so the random quantile method of simulation does not work well. However, the last exercise points the way to an alternative method of simulation.

Show how to simulate a pair of independent, standard normal variables with a pair of random numbers. Using your calculator, simulate 6 values from the standard normal distribution.

Answer

The Rayleigh distribution in the last exercise has CDF $H(r) = 1 - e^{-\frac{1}{2}r^2}$ for $0 \leq r < \infty$, and hence quantile function $H^{-1}(p) = \sqrt{-2 \ln(1-p)}$ for $0 \leq p < 1$. Thus we can simulate the polar radius R with a random number U by $R = \sqrt{-2 \ln(1-U)}$, or a bit more simply by $R = \sqrt{-2 \ln U}$, since $1-U$ is also a random number. We can simulate the polar angle Θ with a random number V by $\Theta = 2\pi V$. Then, a pair of independent, standard normal variables can be simulated by $X = R \cos \Theta$, $Y = R \sin \Theta$.

The Cauchy Distribution

Suppose that X and Y are independent random variables, each with the standard normal distribution. Find the probability density function of $T = X/Y$.

Answer

As usual, let ϕ denote the standard normal PDF, so that $\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}$ for $z \in \mathbb{R}$. Using the [theorem on quotient](#) above, the PDF f of T is given by

$$f(t) = \int_{-\infty}^{\infty} \phi(x)\phi(tx)|x|dx = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-(1+t^2)x^2/2}|x|dx, \quad t \in \mathbb{R} \quad (3.7.51)$$

Using symmetry and a simple substitution,

$$f(t) = \frac{1}{\pi} \int_0^{\infty} x e^{-(1+t^2)x^2/2} dx = \frac{1}{\pi(1+t^2)}, \quad t \in \mathbb{R} \quad (3.7.52)$$

Random variable T has the (standard) *Cauchy distribution*, named after Augustin Cauchy. The Cauchy distribution is studied in detail in the chapter on Special Distributions.

Suppose that a light source is 1 unit away from position 0 on an infinite straight wall. We shine the light at the wall an angle Θ to the perpendicular, where Θ is uniformly distributed on $(-\frac{\pi}{2}, \frac{\pi}{2})$. Find the probability density function of the position of the light beam $X = \tan \Theta$ on the wall.

Answer

The PDF of Θ is $f(\theta) = \frac{1}{\pi}$ for $-\frac{\pi}{2} \leq \theta \leq \frac{\pi}{2}$. The transformation is $x = \tan \theta$ so the inverse transformation is $\theta = \arctan x$. Recall that $\frac{d\theta}{dx} = \frac{1}{1+x^2}$, so by the [change of variables formula](#), X has PDF g given by

$$g(x) = \frac{1}{\pi(1+x^2)}, \quad x \in \mathbb{R} \quad (3.7.53)$$

Thus, X also has the standard Cauchy distribution. Clearly we can simulate a value of the Cauchy distribution by $X = \tan(-\frac{\pi}{2} + \pi U)$ where U is a random number. This is the random quantile method.

Open the Cauchy experiment, which is a simulation of the light problem in the previous exercise. Keep the default parameter values and run the experiment in single step mode a few times. Then run the experiment 1000 times and compare the empirical density function and the probability density function.

3.8: Convergence in Distribution

This section is concerned with the convergence of probability distributions, a topic of basic importance in probability theory. Since we will be almost exclusively concerned with the convergences of sequences of various kinds, it's helpful to introduce the notation $\mathbb{N}_+^* = \mathbb{N}_+ \cup \{\infty\} = \{1, 2, \dots\} \cup \{\infty\}$.

Distributions on $(\mathbb{R}, \mathcal{R})$

Definition

We start with the most important and basic setting, the measurable space $(\mathbb{R}, \mathcal{R})$, where \mathbb{R} is the set of real numbers of course, and \mathcal{R} is the Borel σ -algebra of subsets of \mathbb{R} . Recall that if P is a probability measure on $(\mathbb{R}, \mathcal{R})$, then the function $F : \mathbb{R} \rightarrow [0, 1]$ defined by $F(x) = P(-\infty, x]$ for $x \in \mathbb{R}$ is the (cumulative) distribution function of P . Recall also that F completely determines P . Here is the definition for convergence of probability measures in this setting:

Suppose P_n is a probability measure on $(\mathbb{R}, \mathcal{R})$ with distribution function F_n for each $n \in \mathbb{N}_+^*$. Then P_n converges (weakly) to P_∞ as $n \rightarrow \infty$ if $F_n(x) \rightarrow F_\infty(x)$ as $n \rightarrow \infty$ for every $x \in \mathbb{R}$ where F_∞ is continuous. We write $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$.

Recall that a distribution function F is continuous at $x \in \mathbb{R}$ if and only if $\mathbb{P}(X = x) = 0$, so that x is not an *atom* of the distribution (a point of positive probability). We will see shortly why this condition on F_∞ is appropriate. Of course, a probability measure on $(\mathbb{R}, \mathcal{R})$ is usually associated with a real-valued random variable for some random experiment that is modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} is the σ -algebra of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . If X is a real-valued random variable defined on the probability space, then the *distribution* of X is the probability measure P on $(\mathbb{R}, \mathcal{R})$ defined by $P(A) = \mathbb{P}(X \in A)$ for $A \in \mathcal{R}$, and then of course, the distribution function of X is the function F defined by $F(x) = \mathbb{P}(X \leq x)$ for $x \in \mathbb{R}$. Here is the convergence terminology used in this setting:

Suppose that X_n is a real-valued random variable with distribution P_n for each $n \in \mathbb{N}_+^*$. If $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$ then we say that X_n converges in distribution to X_∞ as $n \rightarrow \infty$. We write $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.

So if F_n is the distribution function of X_n for $n \in \mathbb{N}_+^*$, then $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution if $F_n(x) \rightarrow F_\infty(x)$ at every point $x \in \mathbb{R}$ where F_∞ is continuous. On the one hand, the terminology and notation are helpful, since again most probability measures are associated with random variables (and every probability measure can be). On the other hand, the terminology and notation can be a bit misleading since the random variables, as functions, do not converge in any sense, and indeed the random variables need not be defined on the same probability spaces. It is only the *distributions* that converge. However, often the random variables *are* defined on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$, in which case we can compare convergence in distribution with the other modes of convergence we have or will study:

- Convergence with probability 1
- Convergence in probability
- Convergence in mean

We will show, in fact, that convergence in distribution is the weakest of all of these modes of convergence. However, strength of convergence should not be confused with importance. Convergence in distribution is one of the most important modes of convergence; the central limit theorem, one of the two fundamental theorems of probability, is a theorem about convergence in distribution.

Preliminary Examples

The examples below show why the definition is given in terms of distribution functions, rather than probability density functions, and why convergence is only required at the points of continuity of the limiting distribution function. Note that the distributions considered are probability measures on $(\mathbb{R}, \mathcal{R})$, even though the support of the distribution may be a much smaller subset. For the first example, note that if a deterministic sequence converges in the ordinary calculus sense, then naturally we want the sequence (thought of as random variables) to converge in distribution. Expand the proof to understand the example fully.

Suppose that $x_n \in \mathbb{R}$ for $n \in \mathbb{N}_+^*$. Define random variable $X_n = x_n$ with probability 1 for each $n \in \mathbb{N}_+^*$. Then $x_n \rightarrow x_\infty$ as $n \rightarrow \infty$ if and only if $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.

Proof

For $n \in \mathbb{N}_+^*$, the CDF F_n of X_n is given by $F_n(x) = 0$ for $x < x_n$ and $F_n(x) = 1$ for $x \geq x_n$.

1. Suppose that $x_n \rightarrow x_\infty$ as $n \rightarrow \infty$. If $x < x_\infty$ then $x < x_n$, and hence $F_n(x) = 0$, for all but finitely many $n \in \mathbb{N}_+$, and so $F_n(x) \rightarrow 0$ as $n \rightarrow \infty$. If $x > x_\infty$ then $x > x_n$, and hence $F_n(x) = 1$, for all but finitely many $n \in \mathbb{N}_+$, and so $F_n(x) \rightarrow 1$ as $n \rightarrow \infty$. Nothing can be said about the limiting behavior of $F_n(x_\infty)$ as $n \rightarrow \infty$ without more information. For example, if $x_n \leq x_\infty$ for all but finitely many $n \in \mathbb{N}_+$ then $F_n(x_\infty) \rightarrow 1$ as $n \rightarrow \infty$. If $x_n > x_\infty$ for all but finitely many $n \in \mathbb{N}_+$ then $F_n(x_\infty) \rightarrow 0$ as $n \rightarrow \infty$. If $x_n < x_\infty$ for infinitely many $n \in \mathbb{N}_+$ and $x_n > x_\infty$ for infinitely many $n \in \mathbb{N}_+$ then $F_n(x_\infty)$ does not have a limit as $n \rightarrow \infty$. But regardless, we have $F_n(x) \rightarrow F_\infty(x)$ as $n \rightarrow \infty$ for every $x \in \mathbb{R}$ except perhaps x_∞ , the one point of discontinuity of F_∞ . Hence $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.
2. Conversely, suppose that $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution. If $x < x_\infty$ then $F_n(x) \rightarrow 0$ as $n \rightarrow \infty$ and hence $x < x_n$ for all but finitely many $n \in \mathbb{N}_+$. If $x > x_\infty$ then $F_n(x) \rightarrow 1$ as $n \rightarrow \infty$ and hence $x \geq x_n$ for all but finitely many $n \in \mathbb{N}_+$. So, for every $\epsilon > 0$, $x_n \in (x_\infty - \epsilon, x_\infty + \epsilon)$ for all but finitely many $n \in \mathbb{N}_+$, and hence $x_n \rightarrow x_\infty$ as $n \rightarrow \infty$.

The proof is finished, but let's look at the probability density functions to see that these are not the proper objects of study. For $n \in \mathbb{N}_+^*$, the PDF f_n of X_n is given by $f_n(x_n) = 1$ and $f_n(x) = 0$ for $x \in \mathbb{R} \setminus \{x_n\}$. Only when $x_n = x_\infty$ for all but finitely many $n \in \mathbb{N}_+$ do we have $f_n(x) \rightarrow f(x)$ for $x \in \mathbb{R}$.

For the example below, recall that \mathbb{Q} denotes the set of rational numbers. Once again, expand the proof to understand the example fully

For $n \in \mathbb{N}_+$, let P_n denote the discrete uniform distribution on $\left\{\frac{1}{n}, \frac{2}{n}, \dots, \frac{n-1}{n}, 1\right\}$ and let P_∞ denote the continuous uniform distribution on the interval $[0, 1]$. Then

1. $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$
2. $P_n(\mathbb{Q}) = 1$ for each $n \in \mathbb{N}_+$ but $P_\infty(\mathbb{Q}) = 0$.

Proof

As usual, let F_n denote the CDF of P_n for $n \in \mathbb{N}_+^*$.

1. For $n \in \mathbb{N}_+$ note that F_n is given by $F_n(x) = \lfloor nx \rfloor / n$ for $x \in [0, 1]$. But $nx - 1 \leq \lfloor nx \rfloor \leq nx$ so $\lfloor nx \rfloor / n \rightarrow x$ as $n \rightarrow \infty$ for $x \in [0, 1]$. Of course, $F_n(x) = 0$ for $x < 0$ and $F_n(x) = 1$ for $x > 1$. So $F_n(x) \rightarrow F_\infty(x)$ as $n \rightarrow \infty$ for all $x \in \mathbb{R}$.
2. Note that by definition, so $P_n(\mathbb{Q}) = 1$ for $n \in \mathbb{N}_+$. On the other hand, P_∞ is a continuous distribution and \mathbb{Q} is countable, so $P_\infty(\mathbb{Q}) = 0$.

The proof is finished, but let's look at the probability density functions. For $n \in \mathbb{N}_+$, the PDF f_n of P_n is given by $f_n(x) = \frac{1}{n}$ for $x \in \left\{\frac{1}{n}, \frac{2}{n}, \dots, \frac{n-1}{n}, 1\right\}$ and $f_n(x) = 0$ otherwise. Hence $0 \leq f_n(x) \leq \frac{1}{n}$ for $n \in \mathbb{N}_+$ and $x \in \mathbb{R}$, so $f_n(x) \rightarrow 0$ as $n \rightarrow \infty$ for every $x \in \mathbb{R}$.

The point of the example is that it's reasonable for the discrete uniform distribution on $\left\{\frac{1}{n}, \frac{2}{n}, \dots, \frac{n-1}{n}, 1\right\}$ to converge to the continuous uniform distribution on $[0, 1]$, but once again, the probability density functions are evidently not the correct objects of study.

Probability Density Functions

As the [previous example](#) shows, it is quite possible to have a sequence of discrete distributions converge to a continuous distribution (or the other way around). Recall that probability density functions have very different meanings in the discrete and continuous cases: density with respect to counting measure in the first case, and density with respect to Lebesgue measure in the second case. This is another indication that distribution functions, rather than density functions, are the correct objects of study. However, if probability density functions of a fixed type converge then the distributions converge. Recall again that we are thinking of our probability distributions as measures on $(\mathbb{R}, \mathcal{B})$ even when supported on a smaller subset.

Convergence in distribution in terms of probability density functions.

1. Suppose that f_n is a probability density function for a discrete distribution P_n on a countable set $S \subseteq \mathbb{R}$ for each $n \in \mathbb{N}_+^*$. If $f_n(x) \rightarrow f_\infty(x)$ as $n \rightarrow \infty$ for each $x \in S$ then $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$.
2. Suppose that f_n is a probability density function for a continuous distribution P_n on \mathbb{R} for each $n \in \mathbb{N}_+^*$. If $f_n(x) \rightarrow f(x)$ as $n \rightarrow \infty$ for all $x \in \mathbb{R}$ (except perhaps on a set with Lebesgue measure 0) then $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$.

Proof

1. Fix $x \in \mathbb{R}$. Then $P_n(-\infty, x] = \sum_{y \in S, y \leq x} f(y)$ for $n \in \mathbb{N}_+$ and $P(-\infty, x] = \sum_{y \in S, y \leq x} f(y)$. It follows from [Scheffé's theorem](#) with the measure space $(S, \mathcal{P}(S), \#)$ that $P_n(-\infty, x] \rightarrow P(-\infty, x]$ as $n \rightarrow \infty$.
2. Fix $x \in \mathbb{R}$. Then $P_n(-\infty, x] = \int_{-\infty}^x f(y) dy$ for $n \in \mathbb{N}_+$ and $P(-\infty, x] = \int_{-\infty}^x f(y) dy$. It follows from [Scheffé's theorem](#) with the measure space $(\mathbb{R}, \mathcal{B}, \lambda)$ that $P_n(-\infty, x] \rightarrow P(-\infty, x]$ as $n \rightarrow \infty$.

Convergence in Probability

Naturally, we would like to compare convergence in distribution with other modes of convergence we have studied.

Suppose that X_n is a real-valued random variable for each $n \in \mathbb{N}_+^*$, all defined on the same probability space. If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in probability then $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.

Proof

Let F_n denote the distribution function of X_n for $n \in \mathbb{N}_+^*$. Fix $\epsilon > 0$. Note first that $\mathbb{P}(X_n \leq x) = \mathbb{P}(X_n \leq x, X_\infty \leq x + \epsilon) + \mathbb{P}(X_n \leq x, X_\infty > x + \epsilon)$. Hence $F_n(x) \leq F_\infty(x + \epsilon) + \mathbb{P}(|X_n - X_\infty| > \epsilon)$. Next, note that $\mathbb{P}(X_\infty \leq x - \epsilon) = \mathbb{P}(X_\infty \leq x - \epsilon, X_n \leq x) + \mathbb{P}(X_\infty \leq x - \epsilon, X_n > x)$. Hence $F_\infty(x - \epsilon) \leq F_n(x) + \mathbb{P}(|X_n - X_\infty| > \epsilon)$. From the last two results it follows that

$$F_\infty(x - \epsilon) - \mathbb{P}(|X_n - X_\infty| > \epsilon) \leq F_n(x) \leq F_\infty(x + \epsilon) + \mathbb{P}(|X_n - X_\infty| > \epsilon) \quad (3.8.1)$$

Letting $n \rightarrow \infty$ and using convergence in probability gives

$$F_\infty(x - \epsilon) \leq \liminf_{n \rightarrow \infty} F_n(x) \leq \limsup_{n \rightarrow \infty} F_n(x) \leq F_\infty(x + \epsilon) \quad (3.8.2)$$

Finally, letting $\epsilon \downarrow 0$ we see that if F_∞ is continuous at x then $F_n(x) \rightarrow F_\infty(x)$ as $n \rightarrow \infty$.

Our next example shows that even when the variables are defined on the same probability space, a sequence can converge in distribution, but not in any other way.

Let X be an indicator variable with $\mathbb{P}(X = 0) = \mathbb{P}(X = 1) = \frac{1}{2}$, so that X is the result of tossing a fair coin. Let $X_n = 1 - X$ for $n \in \mathbb{N}_+$. Then

1. $X_n \rightarrow X$ as $n \rightarrow \infty$ in distribution.
2. $\mathbb{P}(X_n \text{ does not converge to } X \text{ as } n \rightarrow \infty) = 1$.
3. X_n does not converge to X as $n \rightarrow \infty$ in probability.
4. X_n does not converge to X as $n \rightarrow \infty$ in mean.

Proof

1. This trivially holds since $1 - X$ has the same distribution as X .
2. This follows since $|X_n - X| = 1$ for every $n \in \mathbb{N}_+$.
3. This follows since $\mathbb{P}(|X_n - X| > \frac{1}{2}) = 1$ for each $n \in \mathbb{N}_+$.
4. This follows since $\mathbb{E}(|X_n - X|) = 1$ for each $n \in \mathbb{N}_+$.

The critical fact that makes this counterexample work is that $1 - X$ has the same distribution as X . Any random variable with this property would work just as well, so if you prefer a counterexample with continuous distributions, let X have probability density function f given by $f(x) = 6x(1 - x)$ for $0 \leq x \leq 1$. The distribution of X is an example of a beta distribution.

The following summary gives the implications for the various modes of convergence; no other implications hold in general.

Suppose that X_n is a real-valued random variable for each $n \in \mathbb{N}_+^*$, all defined on a common probability space.

1. If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ with probability 1 then $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in probability.
2. If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in mean then $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in probability.

3. If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in probability then $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.

It follows that convergence with probability 1, convergence in probability, and convergence in mean all imply convergence in distribution, so the latter mode of convergence is indeed the weakest. However, our next theorem gives an important converse to part (c) in (7), when the limiting variable is a constant. Of course, a constant can be viewed as a random variable defined on any probability space.

Suppose that X_n is a real-valued random variable for each $n \in \mathbb{N}_+$, defined on the same probability space, and that $c \in \mathbb{R}$. If $X_n \rightarrow c$ as $n \rightarrow \infty$ in distribution then $X_n \rightarrow c$ as $n \rightarrow \infty$ in probability.

Proof

Assume that the probability space is $(\Omega, \mathcal{F}, \mathbb{P})$. Note first that $\mathbb{P}(X_n \leq x) \rightarrow 0$ as $n \rightarrow \infty$ if $x < c$ and $\mathbb{P}(X_n \leq x) \rightarrow 1$ as $n \rightarrow \infty$ if $x > c$. It follows that $\mathbb{P}(|X_n - c| \leq \epsilon) \rightarrow 1$ as $n \rightarrow \infty$ for every $\epsilon > 0$.

The Skorohod Representation

As noted in the [summary above](#), convergence in distribution does not imply convergence with probability 1, even when the random variables are defined on the same probability space. However, the next theorem, known as the *Skorohod representation theorem*, gives an important partial result in this direction.

Suppose that P_n is a probability measure on $(\mathbb{R}, \mathcal{B})$ for each $n \in \mathbb{N}_+^*$ and that $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$. Then there exist real-valued random variables X_n for $n \in \mathbb{N}_+^*$, defined on the same probability space, such that

1. X_n has distribution P_n for $n \in \mathbb{N}_+^*$.
2. $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ with probability 1.

Proof

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space and U a random variable defined on this space that is uniformly distributed on the interval $(0, 1)$. For a specific construction, we could take $\Omega = (0, 1)$, \mathcal{F} the σ -algebra of Borel measurable subsets of $(0, 1)$, and \mathbb{P} Lebesgue measure on (Ω, \mathcal{F}) (the uniform distribution on $(0, 1)$). Then let U be the identity function on Ω so that $U(\omega) = \omega$ for $\omega \in \Omega$, so that U has probability distribution \mathbb{P} . We have seen this construction many times before.

1. For $n \in \mathbb{N}_+^*$, let F_n denote the distribution function of P_n and define $X_n = F_n^{-1}(U)$ where F_n^{-1} is the quantile functions of F_n . Recall that X_n has distribution function F_n and therefore X_n has distribution P_n for $n \in \mathbb{N}_+^*$. Of course, these random variables are also defined on $(\Omega, \mathcal{F}, \mathbb{P})$.
2. Let $\epsilon > 0$ and let $u \in (0, 1)$. Pick a continuity point x of F_∞ such that $F_\infty^{-1}(u) - \epsilon < x < F_\infty^{-1}(u)$. Then $F_\infty(x) < u$ and hence $F_n(x) < u$ for all but finitely many $n \in \mathbb{N}_+$. It follows that $F_\infty^{-1}(u) - \epsilon < x < F_n^{-1}(u)$ for all but finitely many $n \in \mathbb{N}_+$. Let $n \rightarrow \infty$ and $u \downarrow 0$ to conclude that $F_\infty^{-1}(u) \leq \liminf_{n \rightarrow \infty} F_n^{-1}(u)$. Next, let v satisfy $0 < u < v < 1$ and let $\epsilon > 0$. Pick a continuity point x of F_∞ such that $F_\infty^{-1}(v) < x < F_\infty^{-1}(v) + \epsilon$. Then $u < v < F_\infty(x)$ and hence $u < F_n(x)$ for all but finitely many $n \in \mathbb{N}_+$. It follows that $F_n^{-1}(u) \leq x < F_\infty^{-1}(v) + \epsilon$ for all but finitely many $n \in \mathbb{N}_+$. Let $n \rightarrow \infty$ and $\epsilon \downarrow 0$ to conclude that $\limsup_{n \rightarrow \infty} F_n^{-1}(u) \leq F_\infty^{-1}(v)$. Letting $v \downarrow u$ it follows that $\limsup_{n \rightarrow \infty} F_n^{-1}(u) \leq F_\infty^{-1}(u)$ if u is a point of continuity of F_∞^{-1} . Therefore $F_n^{-1}(u) \rightarrow F_\infty^{-1}(u)$ as $n \rightarrow \infty$ if u is a point of continuity of F_∞^{-1} . Recall from analysis that since $F_\infty^{-1}(u)$ is increasing, the set $D \subseteq (0, 1)$ of discontinuities of F_∞^{-1} is countable. Since U has a continuous distribution, $\mathbb{P}(U \in D) = 0$. Finally, it follows that $\mathbb{P}(X_n \rightarrow X_\infty \text{ as } n \rightarrow \infty) = 1$.

The following theorem illustrates the value of the Skorohod representation and the usefulness of random variable notation for convergence in distribution. The theorem is also quite intuitive, since a basic idea is that *continuity* should preserve *convergence*.

Suppose that X_n is a real-valued random variable for each $n \in \mathbb{N}_+^*$ (not necessarily defined on the same probability space). Suppose also that $g: \mathbb{R} \rightarrow \mathbb{R}$ is measurable, and let D_g denote the set of discontinuities of g , and P_∞ the distribution of X_∞ . If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution and $P_\infty(D_g) = 0$, then $g(X_n) \rightarrow g(X_\infty)$ as $n \rightarrow \infty$ in distribution.

Proof

By Skorohod's theorem, there exists random variables Y_n for $n \in \mathbb{N}_+^*$, defined on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$, such that Y_n has the same distribution as X_n for $n \in \mathbb{N}_+^*$, and $Y_n \rightarrow Y_\infty$ as $n \rightarrow \infty$ with probability 1. Since

$\mathbb{P}(Y_\infty \in D_g) = P_\infty(D_g) = 0$ it follows that $g(Y_n) \rightarrow g(Y_\infty)$ as $n \rightarrow \infty$ with probability 1. Hence by the [theorem above](#), $g(Y_n) \rightarrow g(Y_\infty)$ as $n \rightarrow \infty$ in distribution. But $g(Y_n)$ has the same distribution as $g(X_n)$ for each $n \in \mathbb{N}_+^*$.

As a simple corollary, if X_n converges X_∞ as $n \rightarrow \infty$ in distribution, and if $a, b \in \mathbb{R}$ then $a + bX_n$ converges to $a + bX$ as $n \rightarrow \infty$ in distribution. But we can do a little better:

Suppose that X_n is a real-valued random variable and that $a_n, b_n \in \mathbb{R}$ for each $n \in \mathbb{N}_+^*$. If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution and if $a_n \rightarrow a_\infty$ and $b_n \rightarrow b_\infty$ as $n \rightarrow \infty$, then $a_n + b_n X_n \rightarrow a + bX_\infty$ as $n \rightarrow \infty$ in distribution.

Proof

Again by [Skorohod's theorem](#), there exist random variables Y_n for $n \in \mathbb{N}_+^*$, defined on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$ such that Y_n has the same distribution as X_n for $n \in \mathbb{N}_+^*$ and $Y_n \rightarrow Y_\infty$ as $n \rightarrow \infty$ with probability 1. Hence also $a_n + b_n Y_n \rightarrow a_\infty + b_\infty Y_\infty$ as $n \rightarrow \infty$ with probability 1. By the [result above](#), $a_n + b_n Y_n \rightarrow a_\infty + b_\infty Y_\infty$ as $n \rightarrow \infty$ in distribution. But $a_n + b_n Y_n$ has the same distribution as $a_n + b_n X_n$ for $n \in \mathbb{N}_+^*$.

The definition of convergence in distribution requires that the sequence of probability measures converge on sets of the form $(-\infty, x]$ for $x \in \mathbb{R}$ when the limiting distribution has probability 0 at x . It turns out that the probability measures will converge on lots of other sets as well, and this result points the way to extending convergence in distribution to more general spaces. To state the result, recall that if A is a subset of a topological space, then the *boundary* of A is $\partial A = \text{cl}(A) \setminus \text{int}(A)$ where $\text{cl}(A)$ is the *closure* of A (the smallest closed set that contains A) and $\text{int}(A)$ is the *interior* of A (the largest open set contained in A).

Suppose that P_n is a probability measure on $(\mathbb{R}, \mathcal{R})$ for $n \in \mathbb{N}_+^*$. Then $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$ if and only if $P_n(A) \rightarrow P_\infty(A)$ as $n \rightarrow \infty$ for every $A \in \mathcal{R}$ with $P(\partial A) = 0$.

Proof

Suppose that $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$. Let X_n be a random variable with distribution P_n for $n \in \mathbb{N}_+^*$. (We don't care about the underlying probability spaces.) If $A \in \mathcal{R}$ then the set of discontinuities of $\mathbf{1}_A$, the indicator function of A , is ∂A . So, suppose $\mathbb{P}_\infty(\partial A) = 0$. By the [continuity theorem above](#), $\mathbf{1}_A(X_n) \rightarrow \mathbf{1}_A(X_\infty)$ as $n \rightarrow \infty$ in distribution. Let G_n denote the CDF of $\mathbf{1}_A(X_n)$ for $n \in \mathbb{N}_+^*$. The only possible points of discontinuity of G_∞ are 0 and 1. Hence $G_n(\frac{1}{2}) \rightarrow G_\infty(\frac{1}{2})$ as $n \rightarrow \infty$. But $G_n(\frac{1}{2}) = P_n(A^c)$ for $n \in \mathbb{N}_+^*$. Hence $P_n(A^c) \rightarrow \mathbb{P}_\infty(A^c)$ and so also $P_n(A) \rightarrow P_\infty(A)$ as $n \rightarrow \infty$.

Conversely, suppose that the condition in the theorem holds. If $x \in \mathbb{R}$, then the boundary of $(-\infty, x]$ is $\{x\}$, so if $P_\infty\{x\} = 0$ then $P_n(-\infty, x] \rightarrow P_\infty(-\infty, x]$ as $n \rightarrow \infty$. So by definition, $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$.

In the context of this result, suppose that $a, b \in \mathbb{R}$ with $a < b$. If $P\{a\} = P\{b\} = 0$, then as $n \rightarrow \infty$ we have $P_n(a, b) \rightarrow P(a, b)$, $P_n[a, b) \rightarrow P[a, b)$, $P_n(a, b] \rightarrow P(a, b]$, and $P_n[a, b] \rightarrow P[a, b]$. Of course, the limiting values are all the same.

Examples and Applications

Next we will explore several interesting examples of the convergence of distributions on $(\mathbb{R}, \mathcal{R})$. There are several important cases where a special distribution converges to another special distribution as a parameter approaches a limiting value. Indeed, such convergence results are part of the reason why such distributions are *special* in the first place.

The Hypergeometric Distribution

Recall that the *hypergeometric distribution* with parameters m , r , and n is the distribution that governs the number of type 1 objects in a sample of size n , drawn without replacement from a population of m objects with r objects of type 1. It has discrete probability density function f given by

$$f(k) = \frac{\binom{r}{k} \binom{m-r}{n-k}}{\binom{m}{n}}, \quad k \in \{0, 1, \dots, n\} \quad (3.8.3)$$

The parameters m , r , and n are positive integers with $n \leq m$ and $r \leq m$. The hypergeometric distribution is studied in more detail in the chapter on Finite Sampling Models

Recall next that *Bernoulli trials* are independent trials, each with two possible outcomes, generically called *success* and *failure*. The probability of success $p \in [0, 1]$ is the same for each trial. The *binomial distribution* with parameters $n \in \mathbb{N}_+$ and p is the distribution of the number successes in n Bernoulli trials. This distribution has probability density function g given by

$$g(k) = \binom{n}{k} p^k (1-p)^{n-k}, \quad k \in \{0, 1, \dots, n\} \quad (3.8.4)$$

The binomial distribution is studied in more detail in the chapter on Bernoulli Trials. Note that the binomial distribution with parameters n and $p = r/m$ is the distribution that governs the number of type 1 objects in a sample of size n , drawn *with replacement* from a population of m objects with r objects of type 1. This fact is motivation for the following result:

Suppose that $r_m \in \{0, 1, \dots, m\}$ for each $m \in \mathbb{N}_+$ and that $r_m/m \rightarrow p$ as $m \rightarrow \infty$. For fixed $n \in \mathbb{N}_+$, the hypergeometric distribution with parameters m , r_m , and n converges to the binomial distribution with parameters n and p as $m \rightarrow \infty$.

Proof

Recall that for $a \in \mathbb{R}$ and $j \in \mathbb{N}$, we let $a^{(j)} = a(a-1) \cdots [a-(j-1)]$ denote the falling power of a of order j . The hypergeometric PDF can be written as

$$f_m(k) = \binom{n}{k} \frac{r_m^{(k)} (m-r_m)^{(n-k)}}{m^{(n)}}, \quad k \in \{0, 1, \dots, n\} \quad (3.8.5)$$

In the fraction above, the numerator and denominator both have n factors. Suppose that we group the k factors in $r_m^{(k)}$ with the first k factors of $m^{(n)}$ and the $n-k$ factors of $(m-r_m)^{(n-k)}$ with the last $n-k$ factors of $m^{(n)}$ to form a product of n fractions. The first k fractions have the form $(r_m - j)/(m - j)$ for some j that does not depend on m . Each of these converges to p as $m \rightarrow \infty$. The last $n-k$ fractions have the form $(m - r_m - j)/(m - k - j)$ for some j that does not depend on m . Each of these converges to $1 - p$ as $m \rightarrow \infty$. Hence

$$f_m(k) \rightarrow \binom{n}{k} p^k (1-p)^{n-k} \text{ as } m \rightarrow \infty \text{ for each } k \in \{0, 1, \dots, n\} \quad (3.8.6)$$

The result now follows from the [theorem above](#) on density functions.

From a practical point of view, the last result means that if the population size m is “large” compared to sample size n , then the hypergeometric distribution with parameters m , r , and n (which corresponds to sampling without replacement) is well approximated by the binomial distribution with parameters n and $p = r/m$ (which corresponds to sampling with replacement). This is often a useful result, not computationally, but rather because the binomial distribution has fewer parameters than the hypergeometric distribution (and often in real problems, the parameters may only be known approximately). Specifically, in the limiting binomial distribution, we do not need to know the population size m and the number of type 1 objects r *individually*, but only in the *ratio* r/m .

In the ball and urn experiment, set $m = 100$ and $r = 30$. For each of the following values of n (the sample size), switch between *sampling without replacement* (the hypergeometric distribution) and *sampling with replacement* (the binomial distribution). Note the difference in the probability density functions. Run the simulation 1000 times for each sampling mode and compare the relative frequency function to the probability density function.

The Binomial Distribution

Recall again that the binomial distribution with parameters $n \in \mathbb{N}_+$ and $p \in [0, 1]$ is the distribution of the number successes in n Bernoulli trials, when p is the probability of success on a trial. This distribution has probability density function f given by

$$f(k) = \binom{n}{k} p^k (1-p)^{n-k}, \quad k \in \{0, 1, \dots, n\} \quad (3.8.7)$$

Recall also that the *Poisson distribution* with parameter $r \in (0, \infty)$ has probability density function g given by

$$g(k) = e^{-r} \frac{r^k}{k!}, \quad k \in \mathbb{N} \quad (3.8.8)$$

The distribution is named for Simeon Poisson and governs the number of “random points” in a region of time or space, under certain ideal conditions. The parameter r is proportional to the size of the region of time or space. The Poisson distribution is studied in more detail in the chapter on the Poisson Process.

Suppose that $p_n \in [0, 1]$ for $n \in \mathbb{N}_+$ and that $np_n \rightarrow r \in (0, \infty)$ as $n \rightarrow \infty$. Then the binomial distribution with parameters n and p_n converges to the Poisson distribution with parameter r as $n \rightarrow \infty$.

Proof

For $k, n \in \mathbb{N}$ with $k \leq n$, the binomial PDF can be written as

$$f_n(k) = \frac{n^{(k)}}{k!} p_n^k (1 - p_n)^{n-k} = \frac{1}{k!} (np_n) [(n-1)p_n] \cdots [(n-k+1)p_n] (1 - p_n)^{n-k} \quad (3.8.9)$$

First, $(n-j)p_n \rightarrow r$ as $n \rightarrow \infty$ for $j \in \{0, 1, \dots, n-1\}$. Next, by a famous limit from calculus, $(1 - p_n)^n = (1 - np_n/n)^n \rightarrow e^{-r}$ as $n \rightarrow \infty$. Hence also $(1 - p_n)^{n-k} \rightarrow e^{-r}$ as $n \rightarrow \infty$ for fixed $k \in \mathbb{N}_+$. Therefore $f_n(k) \rightarrow e^{-r} r^k / k!$ as $n \rightarrow \infty$ for each $k \in \mathbb{N}_+$. The result now follows from the [theorem above](#) on density functions.

From a practical point of view, the convergence of the binomial distribution to the Poisson means that if the number of trials n is “large” and the probability of success p “small”, so that np^2 is small, then the binomial distribution with parameters n and p is well approximated by the Poisson distribution with parameter $r = np$. This is often a useful result, again not computationally, but rather because the Poisson distribution has fewer parameters than the binomial distribution (and often in real problems, the parameters may only be known approximately). Specifically, in the approximating Poisson distribution, we do not need to know the number of trials n and the probability of success p *individually*, but only in the *product* np . As we will see in the next chapter, the condition that np^2 be small means that the variance of the binomial distribution, namely $np(1 - p) = np - np^2$ is approximately $r = np$, which is the variance of the approximating Poisson distribution.

In the binomial timeline experiment, set the parameter values as follows, and observe the graph of the probability density function. (Note that $np = 5$ in each case.) Run the experiment 1000 times in each case and compare the relative frequency function and the probability density function. Note also the successes represented as “random points” in discrete time.

1. $n = 10, p = 0.5$
2. $n = 20, p = 0.25$
3. $n = 100, p = 0.05$

In the Poisson experiment, set $r = 5$ and $t = 1$, to get the Poisson distribution with parameter 5. Note the shape of the probability density function. Run the experiment 1000 times and compare the relative frequency function to the probability density function. Note the similarity between this experiment and the one in the previous exercise.

The Geometric Distribution

Recall that the *geometric distribution* on \mathbb{N}_+ with success parameter $p \in (0, 1]$ has probability density function f given by

$$f(k) = p(1 - p)^{k-1}, \quad k \in \mathbb{N}_+ \quad (3.8.10)$$

The geometric distribution governs the trial number of the first success in a sequence of Bernoulli trials.

Suppose that U has the geometric distribution on \mathbb{N}_+ with success parameter $p \in (0, 1]$. For $n \in \mathbb{N}_+$, the conditional distribution of U given $U \leq n$ converges to the uniform distribution on $\{1, 2, \dots, n\}$ as $p \downarrow 0$.

Proof

The CDF F of U is given by $F(k) = 1 - (1 - p)^k$ for $k \in \mathbb{N}_+$. Hence for $n \in \mathbb{N}_+$, the conditional CDF of U given $U \leq n$ is

$$F_n(k) = \mathbb{P}(U \leq k | U \leq n) = \frac{\mathbb{P}(U \leq k)}{\mathbb{P}(U \leq n)} = \frac{1 - (1-p)^k}{1 - (1-p)^n}, \quad k \in \{1, 2, \dots, n\} \quad (3.8.11)$$

Using L'Hospital's rule, gives $F_n(k) \rightarrow k/n$ as $p \downarrow 0$ for $k \in \{1, 2, \dots, n\}$. As a function of k this is the CDF of the uniform distribution on $\{1, 2, \dots, n\}$.

Next, recall that the *exponential distribution* with rate parameter $r \in (0, \infty)$ has distribution function G given by

$$G(t) = 1 - e^{-rt}, \quad 0 \leq t < \infty \quad (3.8.12)$$

The exponential distribution governs the time between “arrivals” in the Poisson model of random points in time.

Suppose that U_n has the geometric distribution on \mathbb{N}_+ with success parameter $p_n \in (0, 1]$ for $n \in \mathbb{N}_+$, and that $np_n \rightarrow r \in (0, \infty)$ as $n \rightarrow \infty$. The distribution of U_n/n converges to the exponential distribution with parameter r as $n \rightarrow \infty$.

Proof

Let F_n denote the CDF of U_n/n . Then for $x \in [0, \infty)$

$$F_n(x) = \mathbb{P}\left(\frac{U_n}{n} \leq x\right) = \mathbb{P}(U_n \leq nx) = \mathbb{P}(U_n \leq \lfloor nx \rfloor) = 1 - (1-p_n)^{\lfloor nx \rfloor} \quad (3.8.13)$$

We showed in the proof of the [convergence of the binomial distribution](#) that $(1-p_n)^n \rightarrow e^{-r}$ as $n \rightarrow \infty$, and hence $(1-p_n)^{nx} \rightarrow e^{-rx}$ as $n \rightarrow \infty$. But by definition, $\lfloor nx \rfloor \leq nx < \lfloor nx \rfloor + 1$ or equivalently, $nx - 1 < \lfloor nx \rfloor \leq nx$ so it follows from the squeeze theorem that $(1-p_n)^{\lfloor nx \rfloor} \rightarrow e^{-rx}$ as $n \rightarrow \infty$. Hence $F_n(x) \rightarrow 1 - e^{-rx}$ as $n \rightarrow \infty$. As a function of $x \in [0, \infty)$, this is the CDF of the exponential distribution with parameter r .

Note that the limiting condition on n and p in the last result is precisely the same as the condition for the [convergence of the binomial distribution](#) to the Poisson distribution. For a deeper interpretation of both of these results, see the section on the Poisson distribution.

In the negative binomial experiment, set $k = 1$ to get the geometric distribution. Then decrease the value of p and note the shape of the probability density function. With $p = 0.5$ run the experiment 1000 times and compare the relative frequency function to the probability density function.

In the gamma experiment, set $k = 1$ to get the exponential distribution, and set $r = 5$. Note the shape of the probability density function. Run the experiment 1000 times and compare the empirical density function and the probability density function. Compare this experiment with the one in the previous exercise, and note the similarity, up to a change in scale.

The Matching Distribution

For $n \in \mathbb{N}_+$, consider a random permutation (X_1, X_2, \dots, X_n) of the elements in the set $\{1, 2, \dots, n\}$. We say that a *match* occurs at position i if $X_i = i$.

$$\mathbb{P}(X_i = i) = \frac{1}{n} \text{ for each } i \in \{1, 2, \dots, n\}.$$

Proof

The number of permutations of $\{1, 2, \dots, n\}$ is $n!$. For $i \in \{1, 2, \dots, n\}$, the number of such permutations with i in position i is $(n-1)!$. Hence $\mathbb{P}(X_i = i) = (n-1)!/n! = 1/n$. A more direct argument is that i is no more or less likely to end up in position i as any other number.

So the matching events all have the same probability, which varies inversely with the number of trials.

$$\mathbb{P}(X_i = i, X_j = j) = \frac{1}{n(n-1)} \text{ for } i, j \in \{1, 2, \dots, n\} \text{ with } i \neq j.$$

Proof

Again, the number of permutations of $\{1, 2, \dots, n\}$ is $n!$. For distinct $i, j \in \{1, 2, \dots, n\}$, the number of such permutations with i in position i and j in position j is $(n-2)!$. Hence $\mathbb{P}(X_i = i, X_j = j) = (n-2)!/n! = 1/n(n-1)$.

So the matching events are dependent, and in fact are positively correlated. In particular, the matching events do not form a sequence of Bernoulli trials. The matching problem is studied in detail in the chapter on Finite Sampling Models. In that section we show that the number of matches N_n has probability density function f_n given by:

$$f_n(k) = \frac{1}{k!} \sum_{j=0}^{n-k} \frac{(-1)^j}{j!}, \quad k \in \{0, 1, \dots, n\} \quad (3.8.14)$$

The distribution of N_n converges to the Poisson distribution with parameter 1 as $n \rightarrow \infty$.

Proof

For $k \in \mathbb{N}$,

$$f_n(k) = \frac{1}{k!} \sum_{j=0}^{n-k} \frac{(-1)^j}{j!} \rightarrow \frac{1}{k!} \sum_{j=0}^{\infty} \frac{(-1)^j}{j!} = \frac{1}{k!} e^{-1} \quad (3.8.15)$$

As a function of $k \in \mathbb{N}$, this is the PDF of the Poisson distribution with parameter 1. So the result follows from the [theorem above](#) on density functions.

In the matching experiment, increase n and note the apparent convergence of the probability density function for the number of matches. With selected values of n , run the experiment 1000 times and compare the relative frequency function and the probability density function.

The Extreme Value Distribution

Suppose that (X_1, X_2, \dots) is a sequence of independent random variables, each with the standard exponential distribution (parameter 1). Thus, recall that the common distribution function G is given by

$$G(x) = 1 - e^{-x}, \quad 0 \leq x < \infty \quad (3.8.16)$$

As $n \rightarrow \infty$, the distribution of $Y_n = \max\{X_1, X_2, \dots, X_n\} - \ln n$ converges to the distribution with distribution function F given by

$$F(x) = e^{-e^{-x}}, \quad x \in \mathbb{R} \quad (3.8.17)$$

Proof

Let $X_{(n)} = \max\{X_1, X_2, \dots, X_n\}$ and recall that $X_{(n)}$ has CDF G^n . Let F_n denote the CDF of Y_n . For $x \in \mathbb{R}$

$$F_n(x) = \mathbb{P}(Y_n \leq x) = \mathbb{P}(X_{(n)} \leq x + \ln n) = G^n(x + \ln n) = \left[1 - e^{-(x + \ln n)}\right]^n = \left(1 - \frac{e^{-x}}{n}\right)^n \quad (3.8.18)$$

By our famous limit from calculus again, $F_n(x) \rightarrow e^{-e^{-x}}$ as $n \rightarrow \infty$.

The limiting distribution in Exercise (27) is the *standard extreme value distribution*, also known as the *standard Gumbel distribution* in honor of Emil Gumbel. Extreme value distributions are studied in detail in the chapter on Special Distributions.

The Pareto Distribution

Recall that the *Pareto distribution* with shape parameter $a \in (0, \infty)$ has distribution function F given by

$$F(x) = 1 - \frac{1}{x^a}, \quad 1 \leq x < \infty \quad (3.8.19)$$

The Pareto distribution, named for Vilfredo Pareto, is a heavy-tailed distribution sometimes used to model financial variables. It is studied in more detail in the chapter on Special Distributions.

Suppose that X_n has the Pareto distribution with parameter n for each $n \in \mathbb{N}_+$. Then

1. $X_n \rightarrow 1$ as $n \rightarrow \infty$ in distribution (and hence also in probability).
2. The distribution of $Y_n = nX_n - n$ converges to the standard exponential distribution as $n \rightarrow \infty$.

Proof

1. The CDF of X_n is $F_n(x) = 1 - 1/x^n$ for $x \geq 1$. Hence $F_n(x) = 0$ for $n \in \mathbb{N}_+$ and $x \leq 1$ while $F_n(x) \rightarrow 1$ as $n \rightarrow \infty$ for $x > 1$. Thus the limit of F_n agrees with the CDF of the constant 1, except at $x = 1$, the point of discontinuity.
2. Let G_n denote the CDF of Y_n . For $x \geq 0$,

$$G_n(x) = \mathbb{P}(Y_n \leq x) = \mathbb{P}(X_n \leq 1 + x/n) = 1 - \frac{1}{(1 + x/n)^n} \quad (3.8.20)$$

By our famous theorem from calculus again, it follows that $G_n(x) \rightarrow 1 - 1/e^x = 1 - e^{-x}$ as $n \rightarrow \infty$. As a function of $x \in [0, \infty)$, this is the CDF of the standard exponential distribution.

Fundamental Theorems

The two fundamental theorems of basic probability theory, the law of large numbers and the central limit theorem, are studied in detail in the chapter on Random Samples. For this reason we will simply state the results in this section. So suppose that (X_1, X_2, \dots) is a sequence of independent, identically distributed, real-valued random variables (defined on the same probability space) with mean $\mu \in (-\infty, \infty)$ and standard deviation $\sigma \in (0, \infty)$. For $n \in \mathbb{N}_+$, let $Y_n = \sum_{i=1}^n X_i$ denote the sum of the first n variables, $M_n = Y_n/n$ the average of the first n variables, and $Z_n = (Y_n - n\mu)/\sqrt{n}\sigma$ the standard score of Y_n .

The fundamental theorems of probability

1. $M_n \rightarrow \mu$ as $n \rightarrow \infty$ with probability 1 (and hence also in probability and in distribution). This is the *law of large numbers*.
2. The distribution of Z_n converges to the standard normal distribution as $n \rightarrow \infty$. This is the *central limit theorem*.

In part (a), convergence with probability 1 is the *strong law of large numbers* while convergence in probability and in distribution are the *weak laws of large numbers*.

General Spaces

Our next goal is to define convergence of probability distributions on more general measurable spaces. For this discussion, you may need to refer to other sections in this chapter: the integral with respect to a positive measure, properties of the integral, and density functions. In turn, these sections depend on measure theory developed in the chapters on Foundations and Probability Measures.

Definition and Basic Properties

First we need to define the type of measurable spaces that we will use in this subsection.

We assume that (S, d) is a complete, separable metric space and let \mathcal{S} denote the Borel σ -algebra of subsets of S , that is, the σ -algebra generated by the topology. The standard spaces that we often use are special cases of the measurable space (S, \mathcal{S}) :

1. *Discrete*: S is countable and is given the discrete metric so \mathcal{S} is the collection of all subsets of S .
2. *Euclidean*: \mathbb{R}^n is given the standard Euclidean metric so \mathcal{B}_n is the usual σ -algebra of Borel measurable subsets of \mathbb{R}^n .

Additional details

Recall that the metric space (S, d) is *complete* if every Cauchy sequence in S converges to a point in S . The space is *separable* if there exists a countable subset that is dense. A complete, separable metric space is sometimes called a *Polish space* because such spaces were extensively studied by a group of Polish mathematicians in the 1930s, including Kazimierz Kuratowski.

As suggested by our setup, the definition for convergence in distribution involves both measure theory and topology. The motivation is the [theorem above](#) for the one-dimensional Euclidean space $(\mathbb{R}, \mathcal{B})$.

Convergence in distribution:

1. Suppose that P_n is a probability measure on (S, \mathcal{S}) for each $n \in \mathbb{N}_+$. Then P_n *converges (weakly)* to P_∞ as $n \rightarrow \infty$ if $P_n(A) \rightarrow P_\infty(A)$ as $n \rightarrow \infty$ for every $A \in \mathcal{S}$ with $P_\infty(\partial A) = 0$. We write $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$.

2. Suppose that X_n is a random variable with distribution P_n on (S, \mathcal{S}) for each $n \in \mathbb{N}_+^*$. Then X_n converges in distribution to X_∞ as $n \rightarrow \infty$ if $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$. We write $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.

Notes

1. The definition makes sense since $A \in \mathcal{S}$ implies $\partial A \in \mathcal{S}$. Specifically, $\text{cl}(A) \in \mathcal{S}$ because $\text{cl}(A)$ is closed, and $\text{int}(A) \in \mathcal{S}$ because $\text{int}(A)$ is open.
2. The random variables need not be defined on the same probability space.

Let's consider our two special cases. In the discrete case, as usual, the measure theory and topology are not really necessary.

Suppose that P_n is a probability measures on a discrete space (S, \mathcal{S}) for each $n \in \mathbb{N}_+^*$. Then $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$ if and only if $P_n(A) \rightarrow P_\infty(A)$ as $n \rightarrow \infty$ for every $A \subseteq S$.

Proof

This follows from the definition. Every subset is both open and closed so $\partial A = \emptyset$ for every $A \subseteq S$.

In the Euclidean case, it suffices to consider distribution functions, as in the one-dimensional case. If P is a probability measure on $(\mathbb{R}^n, \mathcal{B}_n)$, recall that the *distribution function* F of P is given by

$$F(x_1, x_2, \dots, x_n) = P((-\infty, x_1] \times (-\infty, x_2] \times \dots \times (-\infty, x_n]), \quad (x_1, x_2, \dots, x_n) \in \mathbb{R}^n \quad (3.8.21)$$

Suppose that P_n is a probability measures on $(\mathbb{R}^n, \mathcal{B}_n)$ with distribution function F_n for each $n \in \mathbb{N}_+^*$. Then $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$ if and only if $F_n(\mathbf{x}) \rightarrow F_\infty(\mathbf{x})$ as $n \rightarrow \infty$ for every $\mathbf{x} \in \mathbb{R}^n$ where F_∞ is continuous.

Convergence in Probability

As in the case of $(\mathbb{R}, \mathcal{B})$, convergence in probability implies convergence in distribution.

Suppose that X_n is a random variable with values in S for each $n \in \mathbb{N}_+^*$, all defined on the same probability space. If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in probability then $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.

Notes

Assume that the common probability space is $(\Omega, \mathcal{F}, \mathbb{P})$. Recall that convergence in probability means that $\mathbb{P}[d(X_n, X_\infty) > \epsilon] \rightarrow 0$ as $n \rightarrow \infty$ for every $\epsilon > 0$,

So as before, convergence with probability 1 implies convergence in probability which in turn implies convergence in distribution.

Skorohod's Representation Theorem

As you might guess, [Skorohod's theorem](#) for the one-dimensional Euclidean space $(\mathbb{R}, \mathcal{B})$ can be extended to the more general spaces. However the proof is not nearly as straightforward, because we no longer have the quantile function for constructing random variables on a common probability space.

Suppose that P_n is a probability measures on (S, \mathcal{S}) for each $n \in \mathbb{N}_+^*$ and that $P_n \Rightarrow P_\infty$ as $n \rightarrow \infty$. Then there exists a random variable X_n with values in S for each $n \in \mathbb{N}_+^*$, defined on a common probability space, such that

1. X_n has distribution P_n for $n \in \mathbb{N}_+^*$
2. $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ with probability 1.

One of the main consequences of Skorohod's representation, the preservation of convergence in distribution under continuous functions, is still true and has essentially the same proof. For the general setup, suppose that (S, d, \mathcal{S}) and (T, e, \mathcal{T}) are spaces of the type [described above](#).

Suppose that X_n is a random variable with values in S for each $n \in \mathbb{N}_+^*$ (not necessarily defined on the same probability space). Suppose also that $g: S \rightarrow T$ is measurable, and let D_g denote the set of discontinuities of g , and P_∞ the distribution of X_∞ . If $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution and $P_\infty(D_g) = 0$, then $g(X_n) \rightarrow g(X_\infty)$ as $n \rightarrow \infty$ in distribution.

Proof

By Skorohod's theorem, there exists random variables Y_n with values in S for $n \in \mathbb{N}_+^*$, defined on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$, such that Y_n has the same distribution as X_n for $n \in \mathbb{N}_+^*$, and $Y_n \rightarrow Y_\infty$ as $n \rightarrow \infty$ with probability 1. Since $\mathbb{P}(Y_\infty \in D_g) = P_\infty(D_g) = 0$ it follows that $g(Y_n) \rightarrow g(Y_\infty)$ as $n \rightarrow \infty$ with probability 1. Hence $g(Y_n) \rightarrow g(Y_\infty)$ as $n \rightarrow \infty$ in distribution. But $g(Y_n)$ has the same distribution as $g(X_n)$ for each $n \in \mathbb{N}_+^*$.

A simple consequence of the continuity theorem is that if a sequence of random vectors in \mathbb{R}^n converge in distribution, then the sequence of each coordinate also converges in distribution. Let's just consider the two-dimensional case to keep the notation simple.

Suppose that (X_n, Y_n) is a random variable with values in \mathbb{R}^2 for $n \in \mathbb{N}_+^*$ and that $(X_n, Y_n) \rightarrow (X_\infty, Y_\infty)$ as $n \rightarrow \infty$ in distribution. Then

1. $X_n \rightarrow X_\infty$ as $n \rightarrow \infty$ in distribution.
2. $Y_n \rightarrow Y_\infty$ as $n \rightarrow \infty$ in distribution.

Scheffé's Theorem

Our next discussion concerns an important result known as *Scheffé's theorem*, named after Henry Scheffé. To state our theorem, suppose that (S, \mathcal{S}, μ) is a measure space, so that S is a set, \mathcal{S} is a σ -algebra of subsets of S , and μ is a positive measure on (S, \mathcal{S}) . Further, suppose that P_n is a probability measure on (S, \mathcal{S}) that has density function f_n with respect to μ for each $n \in \mathbb{N}_+$, and that P is a probability measure on (S, \mathcal{S}) that has density function f with respect to μ .

If $f_n(x) \rightarrow f(x)$ as $n \rightarrow \infty$ for almost all $x \in S$ (with respect to μ) then $P_n(A) \rightarrow P(A)$ as $n \rightarrow \infty$ uniformly in $A \in \mathcal{S}$.

Proof

From basic properties of the integral it follows that for $A \in \mathcal{S}$,

$$|P(A) - P_n(A)| = \left| \int_A f d\mu - \int_A f_n d\mu \right| = \left| \int_A (f - f_n) d\mu \right| \leq \int_A |f - f_n| d\mu \leq \int_S |f - f_n| d\mu \quad (3.8.22)$$

Let $g_n = f - f_n$, and let g_n^+ denote the positive part of g_n and g_n^- the negative part of g_n . Note that $g_n^+ \leq f$ and $g_n^+ \rightarrow 0$ as $n \rightarrow \infty$ almost everywhere on S . Since f is a probability density function, it is trivially integrable, so by the dominated convergence theorem, $\int_S g_n^+ d\mu \rightarrow 0$ as $n \rightarrow \infty$. But $\int_{\mathbb{R}} g_n d\mu = 0$ so $\int_{\mathbb{R}} g_n^+ d\mu = \int_{\mathbb{R}} g_n^- d\mu$. Therefore $\int_S |g_n| d\mu = 2 \int_S g_n^+ d\mu \rightarrow 0$ as $n \rightarrow \infty$. Hence $P_n(A) \rightarrow P(A)$ as $n \rightarrow \infty$ uniformly in $A \in \mathcal{S}$.

Of course, the most important special cases of Scheffé's theorem are to discrete distributions and to continuous distributions on a subset of \mathbb{R}^n , as in the [theorem above](#) on density functions.

Expected Value

Generating functions are studied in the chapter on Expected Value. In part, the importance of generating functions stems from the fact that ordinary (pointwise) convergence of a sequence of generating functions corresponds to the convergence of the distributions in the sense of this section. Often it is easier to show convergence in distribution using generating functions than directly from the definition.

In addition, convergence in distribution has elegant characterizations in terms of the convergence of the expected values of certain types of functions of the underlying random variables.

This page titled [3.8: Convergence in Distribution](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist \(Random Services\)](#) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

3.9: General Distribution Functions

Our goal in this section is to define and study functions that play the same role for positive measures on \mathbb{R} that (cumulative) distribution functions do for probability measures on \mathbb{R} . Of course probability measures on \mathbb{R} are usually associated with real-valued random variables. These general *distribution functions* are useful for constructing measures on \mathbb{R} and will appear in our study of integrals with respect to a measure in the next section, as well as non-homogeneous Poisson processes and general renewal processes.

Basic Theory

Throughout this section, our basic measurable space is $(\mathbb{R}, \mathcal{R})$, where \mathcal{R} is the σ -algebra of Borel measurable subsets of \mathbb{R} , and as usual, we will let λ denote Lebesgue measure on $(\mathbb{R}, \mathcal{R})$. As with cumulative distribution functions, it's convenient to have compact notation for the limits of a function $F : \mathbb{R} \rightarrow \mathbb{R}$ from the left and right at $x \in \mathbb{R}$, and at ∞ and $-\infty$ (assuming of course that these limits exist):

$$F(x^+) = \lim_{t \downarrow x} F(t), \quad F(x^-) = \lim_{t \uparrow x} F(t), \quad F(\infty) = \lim_{t \rightarrow \infty} F(t), \quad F(-\infty) = \lim_{t \rightarrow -\infty} F(t) \quad (3.9.1)$$

Distribution Functions and Their Measures

A function $F : \mathbb{R} \rightarrow \mathbb{R}$ that satisfies the following properties is a *distribution function* on \mathbb{R}

1. F is increasing: if $x \leq y$ then $F(x) \leq F(y)$.
2. F is continuous from the right: $F(x^+) = F(x)$ for all $x \in \mathbb{R}$.

Since F is increasing, $F(x^-)$ exists in \mathbb{R} . Similarly $F(\infty)$ exists, as a real number or ∞ , and $F(-\infty)$ exists, as a real number or $-\infty$.

If F is a distribution function on \mathbb{R} , then there exists a unique positive measure μ on \mathcal{R} that satisfies

$$\mu(a, b] = F(b) - F(a), \quad a, b \in \mathbb{R}, \quad a \leq b \quad (3.9.2)$$

Proof

Let \mathcal{J} denote the collection of subsets of \mathbb{R} consisting of intervals of the form $(a, b]$ where $a, b \in \mathbb{R}$ with $a \leq b$, and intervals of the form $(-\infty, a]$ and (a, ∞) where $a \in \mathbb{R}$. Then \mathcal{J} is a semi-algebra. That is, if $A, B \in \mathcal{J}$ then $A \cap B \in \mathcal{J}$, and if $A \in \mathcal{J}$ then A^c is the union of a finite number (actually one or two) sets in \mathcal{J} . We define μ on \mathcal{J} by $\mu(a, b] = F(b) - F(a)$, $\mu(-\infty, a] = F(a) - F(-\infty)$ and $\mu(a, \infty) = F(\infty) - F(a)$. Note that \mathcal{J} contains the empty set via intervals of the form $(a, a]$ where $a \in \mathbb{R}$, but the definition gives $\mu(\emptyset) = 0$. Next, μ is *finitely additive* on \mathcal{J} . That is, if $\{A_i : i \in I\}$ is a finite, disjoint collection of sets in \mathcal{J} and $\bigcup_{i \in I} A_i \in \mathcal{J}$, then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{i \in I} \mu(A_i) \quad (3.9.3)$$

Next, μ is *countably subadditive* on \mathcal{J} . That is, if $A \in \mathcal{J}$ and $A \subseteq \bigcup_{i \in I} A_i$ where $\{A_i : i \in I\}$ is a countable collection of sets in \mathcal{J} then

$$\mu(A) \leq \sum_{i \in I} \mu(A_i) \quad (3.9.4)$$

Finally, μ is clearly σ -finite on \mathcal{J} since $\mu(a, b] < \infty$ for $a, b \in \mathbb{R}$ with $a < b$, and \mathbb{R} is a countable, disjoint union of intervals of this form. Hence it follows from the basic extension and uniqueness theorems that μ can be extended uniquely to a measure on the $\mathcal{R} = \sigma(\mathcal{J})$.

For the final uniqueness part, suppose that μ is a measure on \mathcal{R} satisfying $\mu(a, b] = F(b) - F(a)$ for $a, b \in \mathbb{R}$ with $a < b$. Then by the continuity theorem for increasing sets, $\mu(-\infty, a] = F(a) - F(-\infty)$ and $\mu(a, \infty) = F(\infty) - F(a)$ for $a \in \mathbb{R}$. Hence μ is the unique measure constructed above.

The measure μ is called the *Lebesgue-Stieltjes measure* associated with F , named for Henri Lebesgue and Thomas Joannes Stieltjes. A very rich variety of measures on \mathbb{R} can be constructed in this way. In particular, when the function F takes values in $[0, 1]$, the associated measure \mathbb{P} is a probability measure. Another special case of interest is the distribution function defined by $F(x) = x$ for $x \in \mathbb{R}$, in which case $\mu(a, b]$ is the length of the interval $(a, b]$ and therefore $\mu = \lambda$, Lebesgue measure on \mathcal{R} . But although the measure associated with a distribution function is unique, the distribution function itself is not. Note that if $c \in \mathbb{R}$ then the distribution function defined by $F(x) = x + c$ for $x \in \mathbb{R}$ also generates Lebesgue measure. This example captures the general situation.

Suppose that F and G are distribution functions that generate the same measure μ on \mathbb{R} . Then there exists $c \in \mathbb{R}$ such that $G = F + c$.

Proof

For $x \in \mathbb{R}$, note that $F(x) - F(0) = G(x) - G(0)$. The common value is $\mu(0, x]$ if $x \geq 0$ and $-\mu(x, 0]$ if $x < 0$. Thus $G(x) = F(x) - F(0) + G(0)$ for $x \in \mathbb{R}$.

Returning to the case of a probability measure \mathbb{P} on \mathbb{R} , the cumulative distribution function F that we studied in this chapter is the unique distribution function satisfying $F(-\infty) = 0$. More generally, having constructed a measure from a distribution function, let's now consider the complementary problem of finding a distribution function for a given measure. The proof of the last theorem points the way.

Suppose that μ is a positive measure on $(\mathbb{R}, \mathcal{R})$ with the property that $\mu(A) < \infty$ if A is bounded. Then there exists a distribution function that generates μ .

Proof

Define F on \mathbb{R} by

$$F(x) = \begin{cases} \mu(0, x], & x \geq 0 \\ -\mu(x, 0], & x < 0 \end{cases} \quad (3.9.5)$$

Then $F : \mathbb{R} \rightarrow \mathbb{R}$ by the assumption on μ . Also F is increasing: if $0 \leq x \leq y$ then $\mu(0, x] \leq \mu(0, y]$ by the increasing property of a positive measure. Similarly, if $x \leq y \leq 0$, the $\mu(x, 0] \geq \mu(y, 0]$, so $-\mu(x, 0] \leq -\mu(y, 0]$. Finally, if $x \leq 0 \leq y$, then $-\mu(x, 0] \leq 0$ and $\mu(0, y] \geq 0$. Next, F is continuous from the right: Suppose that $x_n \in \mathbb{R}$ for $n \in \mathbb{N}_+$ and $x_n \downarrow x$ as $n \rightarrow \infty$. If $x \geq 0$ then $\mu(0, x_n] \downarrow \mu(0, x]$ by the continuity theorem for decreasing sets, which applies since the measures are finite. If $x < 0$ then $\mu(x_n, 0] \uparrow \mu(x, 0]$ by the continuity theorem for increasing sets. So in both cases, $F(x_n) \downarrow F(x)$ as $n \rightarrow \infty$. Hence F is a distribution function, and it remains to show that it generates μ . Let $a, b \in \mathbb{R}$ with $a \leq b$. If $a \geq 0$ then $\mu(a, b] = \mu(0, b] - \mu(0, a] = F(b) - F(a)$ by the difference property of a positive measure. Similarly, if $b \leq 0$ then $\mu(a, b] = \mu(a, 0] - \mu(b, 0] = -F(a) + F(b)$. Finally, if $a \leq 0$ and $b \geq 0$, then $\mu(a, b] = \mu(a, 0] + \mu(0, b] = -F(a) + F(b)$.

In the proof of the last theorem, the use of 0 as a “reference point” is arbitrary, of course. Any other point in \mathbb{R} would do as well, and would produce a distribution function that differs from the one in the proof by a constant. If μ has the property that $\mu(-\infty, x] < \infty$ for $x \in \mathbb{R}$, then it's easy to see that F defined by $F(x) = \mu(-\infty, x]$ for $x \in \mathbb{R}$ is a distribution function that generates μ , and is the unique distribution function with $F(-\infty) = 0$. Of course, in the case of a probability measure, this is the cumulative distribution function, as noted above.

Properties

General distribution functions enjoy many of the same properties as the cumulative distribution function (but not all because of the lack of uniqueness). In particular, we can easily compute the measure of any interval from the distribution function.

Suppose that F is a distribution function and μ is the positive measure on $(\mathbb{R}, \mathcal{R})$ associated with F . For $a, b \in \mathbb{R}$ with $a < b$,

1. $\mu[a, b] = F(b) - F(a^-)$
2. $\mu\{a\} = F(a) - F(a^-)$
3. $\mu(a, b) = F(b^-) - F(a)$
4. $\mu[a, b) = F(b^-) - F(a^-)$

Proof

All of these results follow from the continuity theorems for a positive measure. Suppose that (x_1, x_2, \dots) is a sequence of distinct points in \mathbb{R} .

1. If $x_n \uparrow a$ as $n \rightarrow \infty$ then $(x_n, b] \uparrow [a, b]$ so $\mu(x_n, b] \uparrow \mu[a, b]$ as $n \rightarrow \infty$. But also $\mu(x_n, b] = F(b) - F(x_n) \rightarrow F(b) - F(a^-)$ as $n \rightarrow \infty$.
2. This follows from (a) by taking $a = b$
3. If $x_n \uparrow b$ as $n \rightarrow \infty$ then $(a, x_n] \uparrow (a, b)$ so $\mu(a, x_n] \uparrow \mu(a, b)$ as $n \rightarrow \infty$. But also $\mu(a, x_n] = F(x_n) - F(a) \rightarrow F(b^-) - F(a)$ as $n \rightarrow \infty$.
4. From (a) and (b) and the difference rule,

$$\mu[a, b] = \mu[a, b] - \mu\{b\} = F(b) - F(a^-) - [F(b) - F(b^-)] = F(b^-) - F(a^-) \quad (3.9.6)$$

Note that F is continuous at $x \in \mathbb{R}$ if and only if $\mu\{x\} = 0$. In particular, μ is a *continuous measure* (recall that this means that $\mu\{x\} = 0$ for all $x \in \mathbb{R}$) if and only if F is continuous on \mathbb{R} . On the other hand, F is discontinuous at $x \in \mathbb{R}$ if and only if $\mu\{x\} > 0$, so that μ has an *atom* at x . So μ is a *discrete measure* (recall that this means that μ has countable support) if and only if F is a step function.

Suppose again that F is a distribution function and μ is the positive measure on $(\mathbb{R}, \mathcal{R})$ associated with F . If $a \in \mathbb{R}$ then

1. $\mu(a, \infty) = F(\infty) - F(a)$
2. $\mu[a, \infty) = F(\infty) - F(a^-)$
3. $\mu(-\infty, a] = F(a) - F(-\infty)$
4. $\mu(-\infty, a) = F(a^-) - F(-\infty)$
5. $\mu(\mathbb{R}) = F(\infty) - F(-\infty)$

Proof

The proofs, as before, just use the continuity theorems. Suppose that (x_1, x_2, \dots) is a sequence of distinct points in \mathbb{R}

1. If $x_n \uparrow \infty$ as $n \rightarrow \infty$ then $(a, x_n] \uparrow (a, \infty)$ so $\mu(a, x_n] \uparrow \mu(a, \infty)$ as $n \rightarrow \infty$. But also $\mu(a, x_n] = F(x_n) - F(a) \rightarrow F(\infty) - F(a)$ as $n \rightarrow \infty$
2. Similarly, if $x_n \uparrow \infty$ as $n \rightarrow \infty$ then $[a, x_n] \uparrow [a, \infty)$ so $\mu[a, x_n] \uparrow \mu[a, \infty)$ as $n \rightarrow \infty$. But also $\mu[a, x_n] = F(x_n) - F(a^-) \rightarrow F(\infty) - F(a^-)$ as $n \rightarrow \infty$
3. If $x_n \downarrow -\infty$ as $n \rightarrow \infty$ then $(x_n, a] \uparrow (-\infty, a]$ so $\mu(x_n, a] \uparrow \mu(-\infty, a]$ as $n \rightarrow \infty$. But also $\mu(x_n, a] = F(a) - F(x_n) \rightarrow F(a) - F(-\infty)$ as $n \rightarrow \infty$
4. Similarly, if $x_n \downarrow -\infty$ as $n \rightarrow \infty$ then $(x_n, a) \uparrow (-\infty, a)$ so $\mu(x_n, a) \uparrow \mu(-\infty, a)$ as $n \rightarrow \infty$. But also $\mu(x_n, a) = F(a^-) - F(x_n) \rightarrow F(a^-) - F(-\infty)$ as $n \rightarrow \infty$
5. $\mu(\mathbb{R}) = \mu(-\infty, 0] + \mu(0, \infty) = [F(0) - F(-\infty)] + [F(\infty) - F(0)] = F(\infty) - F(-\infty)$

Distribution Functions on $[0, \infty)$

Positive measures and distribution functions on $[0, \infty)$ are particularly important in renewal theory and Poisson processes, because they model random times.

The discrete case. Suppose that G is discrete, so that there exists a countable set $C \subset [0, \infty)$ with $G(C^c) = 0$. Let $g(t) = G\{t\}$ for $t \in C$ so that g is the density function of G with respect to counting measure on C . If $u : [0, \infty) \rightarrow \mathbb{R}$ is locally bounded then

$$\int_0^t u(s) dG(s) = \sum_{s \in C \cap [0, t]} u(s)g(s) \quad (3.9.7)$$

Figure 3.9.1: A discrete measure

In the discrete case, the distribution is often *arithmetic*. Recall that this means that the countable set C is of the form $\{nd : n \in \mathbb{N}\}$ for some $d \in (0, \infty)$. In the following results,

The continuous case. Suppose that G is absolutely continuous with respect to Lebesgue measure on $[0, \infty)$ with density function $g : [0, \infty) \rightarrow [0, \infty)$. If $u : [0, \infty) \rightarrow \mathbb{R}$ is locally bounded then

$$\int_0^t u(s) dG(s) = \int_0^t u(s)g(s) ds \quad (3.9.8)$$

Figure 3.9.2: A continuous measure

The mixed case. Suppose that there exists a countable set $C \subset [0, \infty)$ with $G(C) > 0$ and $G(C^c) > 0$, and that G restricted to subsets of C^c is absolutely continuous with respect to Lebesgue measure. Let $g(t) = G'\{t\}$ for $t \in C$ and let h be a density with respect to Lebesgue measure of G restricted to subsets of C^c . If $u : [0, \infty) \rightarrow \mathbb{R}$ is locally bounded then,

$$\int_0^t u(s) dG(s) = \sum_{s \in C \cap [0, t]} u(s)g(s) + \int_0^t u(s)h(s) ds \quad (3.9.9)$$

Figure 3.9.3: A mixed measure

The three special cases do not exhaust the possibilities, but are by far the most common cases in applied problems.

3.10: The Integral With Respect to a Measure

Probability density functions have very different interpretations for discrete distributions as opposed to continuous distributions. For a discrete distribution, the probability of an event is computed by summing the density function over the outcomes in the event, while for a continuous distribution, the probability is computed by integrating the density function over the outcomes. For a mixed distributions, we have partial discrete and continuous density functions and the probability of an event is computed by summing and integrating. The various types of density functions can unified under a general theory of integration, which is the subject of this section. This theory has enormous importance in probability, far beyond just density functions. Expected value, which we consider in the next chapter, can be interpreted as an integral with respect to a probability measure. Beyond probability, the general theory of integration is of fundamental importance in many areas of mathematics.

Basic Theory

Definitions

Our starting point is a measure space (S, \mathcal{S}, μ) . That is, S is a set, \mathcal{S} is a σ -algebra of subsets of S , and μ is a positive measure on \mathcal{S} . As usual, the most important special cases are

- *Euclidean space*: $S = \mathbb{R}^n$ for some $n \in \mathbb{N}_+$, $\mathcal{S} = \mathcal{R}_n$, the σ -algebra of Lebesgue measurable subsets of \mathbb{R}^n , and $\mu = \lambda_n$, standard n -dimensional Lebesgue measure.
- *Discrete space*: S is a countable set, \mathcal{S} is the collection of all subsets of S , and $\mu = \#$, counting measure.
- *Probability space*: S is the set of outcomes of a random experiment, \mathcal{S} is the σ -algebra of events, and $\mu = \mathbb{P}$, a probability measure.

The following definition reflects the fact that in measure theory, sets of measure 0 are often considered unimportant.

Consider a statement with $x \in S$ as a free variable. Technically such a statement is a *predicate* on S . Suppose that $A \in \mathcal{S}$.

1. The statement holds *on* A if it is true for every $x \in A$.
2. The statement holds *almost everywhere on* A (with respect to μ) if there exists $B \in \mathcal{S}$ with $B \subseteq A$ such that the statement holds on B and $\mu(A \setminus B) = 0$.

A typical statement that we have in mind is an equation or an inequality with $x \in S$ as a free variable. Our goal is to define the *integral* of certain measurable functions $f : S \rightarrow \mathbb{R}$, with respect to the measure μ . The integral may exist as a number in \mathbb{R} (in which case we say that f is *integrable*), or may exist as ∞ or $-\infty$, or may not exist at all. When it exists, the integral is denoted variously by

$$\int_S f d\mu, \int_S f(x) d\mu(x), \int_S f(x) \mu(dx) \quad (3.10.1)$$

We will use the first two.

Since the set of extended real numbers $\mathbb{R}^* = \mathbb{R} \cup \{-\infty, \infty\}$ plays an important role in the theory, we need to recall the arithmetic of ∞ and $-\infty$. Here are the conventions that are appropriate for integration:

Arithmetic on \mathbb{R}^*

1. If $a \in (0, \infty]$ then $a \cdot \infty = \infty$ and $a \cdot (-\infty) = -\infty$
2. If $a \in [-\infty, 0)$ then $a \cdot \infty = -\infty$ and $a \cdot (-\infty) = \infty$
3. $0 \cdot \infty = 0$ and $0 \cdot (-\infty) = 0$
4. If $a \in \mathbb{R}$ then $a + \infty = \infty$ and $a + (-\infty) = -\infty$
5. $\infty + \infty = \infty$
6. $-\infty + (-\infty) = -\infty$

However, $\infty - \infty$ is not defined (because it does not make consistent sense) and we must be careful never to produce this indeterminate form. You might recall from calculus that $0 \cdot \infty$ is also an indeterminate form. However, for the theory of integration, the convention that $0 \cdot \infty = 0$ is convenient and consistent. In terms of order of course, $-\infty < a < \infty$ for $a \in \mathbb{R}$.

We also need to extend topology and measure to \mathbb{R}^* . In terms of the first, $(a, \infty]$ is an open neighborhood of ∞ and $[-\infty, a)$ is an open neighborhood of $-\infty$ for every $a \in \mathbb{R}$. This ensures that if $x_n \in \mathbb{R}$ for $n \in \mathbb{N}_+$ then $x_n \rightarrow \infty$ or $x_n \rightarrow -\infty$ as $n \rightarrow \infty$ has its usual calculus meaning. Technically this topology results in the *two-point compactification* of \mathbb{R} . Now we can give \mathbb{R}^* the Borel σ -algebra \mathcal{R}^* , that is, the σ -algebra generated by the topology. Basically, this simply means that if $A \in \mathcal{R}$ then $A \cup \{\infty\}$, $A \cup \{-\infty\}$, and $A \cup \{-\infty, \infty\}$ are all in \mathcal{R}^* .

Desired Properties

As motivation for the definition, every version of integration should satisfy some basic properties. First, the integral of the indicator function of a measurable set should simply be the size of the set, as measured by μ . This gives our first definition:

If $A \in \mathcal{S}$ then $\int_S \mathbf{1}_A d\mu = \mu(A)$.

This definition hints at the intimate relationship between measure and integration. We will construct the integral from the measure μ in this section, but this first property shows that if we started with the integral, we could recover the measure. This property also shows why we need ∞ as a possible value of the integral, and coupled with some of the properties below, why $-\infty$ is also needed. Here is a simple corollary of our first definition.

$$\int_S 0 d\mu = 0$$

Proof

Note that $\int_S 0 d\mu = \int_S \mathbf{1}_\emptyset d\mu = \mu(\emptyset) = 0$.

We give three more essential properties that we want. First are the *linearity properties* in two parts—part (a) is the *additive property* and part (b) is the *scaling property*.

If $f, g : S \rightarrow \mathbb{R}$ are measurable functions whose integrals exist, and $c \in \mathbb{R}$, then

1. $\int_S (f + g) d\mu = \int_S f d\mu + \int_S g d\mu$ as long as the right side is not of the form $\infty - \infty$
2. $\int_S cf d\mu = c \int_S f d\mu$.

The additive property almost implies the scaling property

The steps below do not constitute a proof because questions of the existence of the integrals are ignored and because the limit interchange in the last step is not justified. Still, the argument shows the close relationship between the additive property and the scaling property.

1. If $n \in \mathbb{N}_+$, then by (a) and induction, $\int_S nf d\mu = n \int_S f d\mu$.
2. From step (1), if $n \in \mathbb{N}_+$ then $\int_S f d\mu = \int_S n \frac{1}{n} f d\mu = n \int_S \frac{1}{n} f d\mu$ so $\int_S \frac{1}{n} f d\mu = \frac{1}{n} \int_S f d\mu$.
3. If $m, n \in \mathbb{N}_+$ then from steps (1) and (2) $\int_S \frac{m}{n} f d\mu = m \int_S \frac{1}{n} f d\mu = \frac{m}{n} \int_S f d\mu$.
4. $0 = \int_S 0 d\mu = \int_S (f - f) d\mu = \int_S f d\mu + \int_S -f d\mu$ so $\int_S -f d\mu = - \int_S f d\mu$.
5. By steps (3) and (4), $\int_S cf d\mu = c \int_S f d\mu$ for every $c \in \mathbb{Q}$ (the set of rational real numbers).
6. If $c \in \mathbb{R}$ there exists $c_n \in \mathbb{Q}$ for $n \in \mathbb{N}_+$ with $c_n \rightarrow c$ as $n \rightarrow \infty$. By step (5), $\int_S c_n f d\mu = c_n \int_S f d\mu$.
7. Taking limits in step (6) suggests $\int_S cf d\mu = c \int_S f d\mu$.

To be more explicit, we want the additivity property (a) to hold if at least one of the integrals on the right is finite, or if both are ∞ or if both are $-\infty$. What is ruled out are the two cases where one integral is ∞ and the other is $-\infty$, and this is what is meant by the indeterminate form $\infty - \infty$. Our next essential properties are the *order properties*, again in two parts—part (a) is the *positive property* and part (b) is the *increasing property*.

Suppose that $f, g : S \rightarrow \mathbb{R}$ are measurable.

1. If $f \geq 0$ on S then $\int_S f d\mu \geq 0$.
2. If the integrals of f and g exist and $f \leq g$ on S then $\int_S f d\mu \leq \int_S g d\mu$

The positive property and the additive property imply the increasing property

Implicit in part (a) is that the integral of a nonnegative, measurable function always exists in $[0, \infty]$. Suppose that the integrals of f and g exist and $f \leq g$ on S . Then $g - f \geq 0$ on S and $g = f + (g - f)$. If $\int_S f d\mu = -\infty$, then trivially, $\int_S f d\mu \leq \int_S g d\mu$. Otherwise, by the additivity property,

$$\int_S g d\mu = \int_S f d\mu + \int_S (g - f) d\mu \quad (3.10.2)$$

But $\int_S (g - f) d\mu \geq 0$ (so in particular the right side is not $-\infty + \infty$), and hence $\int_S g d\mu \geq \int_S f d\mu$

Our last essential property is perhaps the least intuitive, but is a type of *continuity property* of integration, and is closely related to the continuity property of positive measure. The official name is the *monotone convergence theorem*.

Suppose that $f_n : S \rightarrow [0, \infty)$ is measurable for $n \in \mathbb{N}_+$ and that f_n is increasing in n . Then

$$\int_S \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu \quad (3.10.3)$$

Note that since f_n is increasing in n , $\lim_{n \rightarrow \infty} f_n(x)$ exists in $\mathbb{R} \cup \{\infty\}$ for each $x \in \mathbb{R}$ (and the limit defines a measurable function). This property shows that it is sometimes convenient to allow nonnegative functions to take the value ∞ . Note also that by the [increasing property](#), $\int_S f_n d\mu$ is increasing in n and hence also has a limit in $\mathbb{R} \cup \{\infty\}$.

To see the connection with measure, suppose that (A_1, A_2, \dots) is an increasing sequence of sets in \mathcal{S} , and let $A = \bigcup_{i=1}^{\infty} A_i$. Note that $\mathbf{1}_{A_n}$ is increasing in $n \in \mathbb{N}_+$ and $\mathbf{1}_{A_n} \rightarrow \mathbf{1}_A$ as $n \rightarrow \infty$. For this reason, the union A is sometimes called the *limit* of A_n as $n \rightarrow \infty$. The continuity theorem of positive measure states that $\mu(A_n) \rightarrow \mu(A)$ as $n \rightarrow \infty$. Equivalently, $\int_S \mathbf{1}_{A_n} d\mu \rightarrow \int_S \mathbf{1}_A d\mu$ as $n \rightarrow \infty$, so the continuity theorem of positive measure is a special case of the monotone convergence theorem.

Armed with the properties that we want, the definition of the integral is fairly straightforward, and proceeds in stages. We give the definition successively for

1. Nonnegative simple functions
2. Nonnegative measurable functions
3. Measurable real-valued functions

Of course, each definition should agree with the previous one on the functions that are in both collections.

Simple Functions

A *simple function* on S is simply a measurable, real-valued function with finite range. Simple functions are usually expressed as linear combinations of indicator functions.

Representations of simple functions

1. Suppose that I is a finite index set, $a_i \in \mathbb{R}$ for each $i \in I$, and $\{A_i : i \in I\}$ is a collection of sets in \mathcal{S} that partition S . Then $f = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ is a simple function. Expressing a simple function in this form is a *representation* of f .
2. A simple function f has a unique representation as $f = \sum_{j \in J} b_j \mathbf{1}_{B_j}$ where J is a finite index set, $\{b_j : j \in J\}$ is a set of distinct real numbers, and $\{B_j : j \in J\}$ is a collection of nonempty sets in \mathcal{S} that partition S . This representation is known as the *canonical representation*.

Proof

1. Note that f is measurable since $A_i \in \mathcal{S}$ for each $i \in I$. Also f has finite range since I is finite. Specifically, the range of f consists of the distinct a_i for $i \in I$ with $A_i \neq \emptyset$.
2. Suppose that f is simple. Let $\{b_j : j \in J\}$ denote the (distinct) values in the range of f and let $B_j = f^{-1}\{b_j\}$ for $j \in J$. Then J is finite, $\{B_j : j \in J\}$ is a collection of nonempty sets in \mathcal{S} that partition S , and $f = \sum_{j \in J} b_j \mathbf{1}_{B_j}$. Conversely, suppose that f has a representation of this form. Then $\{b_j : j \in J\}$ is the range of f and $B_j = f^{-1}\{b_j\}$ so the representation is unique.

You might wonder why we don't just always use the canonical representation for simple functions. The problem is that even if we start with canonical representations, when we combine simple functions in various ways, the resulting representations may not be canonical. The collection of simple functions is closed under the basic arithmetic operations, and in particular, forms a vector space.

Suppose that f and g are simple functions with representations $f = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ and $g = \sum_{j \in J} b_j \mathbf{1}_{B_j}$, and that $c \in \mathbb{R}$. Then

1. $f + g$ is simple, with representation $f + g = \sum_{(i,j) \in I \times J} (a_i + b_j) \mathbf{1}_{A_i \cap B_j}$.
2. fg is simple, with representation $fg = \sum_{(i,j) \in I \times J} (a_i b_j) \mathbf{1}_{A_i \cap B_j}$.
3. cf is simple, with representation $cf = \sum_{i \in I} ca_i \mathbf{1}_{A_i}$.

Proof

Since f and g are measurable, so are $f + g$, fg , and cf . Moreover, since f and g have finite range, so do $f + g$, fg , and cf . For the representations in parts (a) and (b), note that $I \times J$ is finite, $\{A_i \cap B_j : (i, j) \in I \times J\}$ is a collection of sets in \mathcal{S} that partition S , and on $A_i \cap B_j$, $f + g = a_i + b_j$ and $fg = a_i b_j$.

As we alluded to earlier, note that even if the representations of f and g are canonical, the representations for $f + g$ and fg may not be. The next result treats composition, and will be important for the change of variables theorem in the next section.

Suppose that (T, \mathcal{T}) is another measurable space, and that $f : S \rightarrow T$ is measurable. If g is a simple function on T with representation $g = \sum_{i \in I} b_i \mathbf{1}_{B_i}$, then $g \circ f$ is a simple function on S with representation $g \circ f = \sum_{i \in I} b_i \mathbf{1}_{f^{-1}(B_i)}$.

Proof

Recall that $g \circ f : S \rightarrow \mathbb{R}$ and $\text{range}(g \circ f) \subseteq \text{range}(g)$ so $g \circ f$ has finite range. f is measurable, and inverse images preserve all set operations, so $\{f^{-1}(B_i) : i \in I\}$ is a measurable partition of S . Finally, if $x \in f^{-1}(B_i)$ then $f(x) \in B_i$ so $g[f(x)] = b_i$.

Given the definition of the integral of an indicator function in (3) and that we want the linearity property (5) to hold, there is no question as to how we should define the integral of a nonnegative simple function.

Suppose that f is a nonnegative simple function, with the representation $f = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ where $a_i \geq 0$ for $i \in I$. We define

$$\int_S f d\mu = \sum_{i \in I} a_i \mu(A_i) \quad (3.10.4)$$

The definition is consistent

Consistency refers to the fact that a simple function can have more than one representation as a linear combination of indicator functions, and hence we must show that all such representations lead to the same value for the integral. Let $\{b_j : j \in J\}$ denote the set of distinct elements among the numbers a_i where $i \in I$ and $A_i \neq \emptyset$. For $j \in J$, let $I_j = \{i \in I : a_i = b_j\}$ and let $B_j = \bigcup_{i \in I_j} A_i$. Thus, $f = \sum_{j \in J} b_j \mathbf{1}_{B_j}$, and this is the canonical representation. Note that

$$\sum_{i \in I} a_i \mu(A_i) = \sum_{j \in J} \sum_{i \in I_j} a_i \mu(A_i) = \sum_{j \in J} b_j \sum_{i \in I_j} \mu(A_i) = \sum_{j \in J} b_j \mu(B_j) \quad (3.10.5)$$

The first sum is the integral defined in terms of the general representation $f = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ while the last sum is the integral defined in terms of the unique canonical representation $f = \sum_{j \in J} b_j \mathbf{1}_{B_j}$. Thus, any representation of a simple function f leads to the same value for the integral.

Note that if f is a nonnegative simple function, then $\int_S f d\mu$ exists in $[0, \infty]$, so the [order properties](#) holds. We next show that the [linearity properties](#) are satisfied for nonnegative simple functions.

Suppose that f and g are nonnegative simple functions, and that $c \in [0, \infty)$. Then

1. $\int_S (f+g) d\mu = \int_S f d\mu + \int_S g d\mu$
2. $\int_S cf d\mu = c \int_S f d\mu$

Proof

Suppose that f and g are nonnegative simple functions with the representations $f = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ and $g = \sum_{j \in J} b_j \mathbf{1}_{B_j}$. Thus $a_i \geq 0$ for $i \in I$, $b_j \geq 0$ for $j \in J$, and $\int_S f d\mu = \sum_{i \in I} a_i \mu(A_i)$ and $\int_S g d\mu = \sum_{j \in J} b_j \mu(B_j)$.

1. As noted above, $f+g$ has the representation

$$f+g = \sum_{(i,j) \in I \times J} (a_i + b_j) \mathbf{1}_{A_i \cap B_j} \quad (3.10.6)$$

Note that $\{A_i \cap B_j : j \in J\}$ is a partition of A_i for each $i \in I$, and similarly $\{A_i \cap B_j : i \in I\}$ is a partition of B_j for each $j \in J$. Hence

$$\int_S (f+g) d\mu = \sum_{(i,j) \in I \times J} (a_i + b_j) \mu(A_i \cap B_j) \quad (3.10.7)$$

$$= \sum_{i \in I} \sum_{j \in J} a_i \mu(A_i \cap B_j) + \sum_{j \in J} \sum_{i \in I} b_j \mu(A_i \cap B_j) \quad (3.10.8)$$

$$= \sum_{i \in I} a_i \mu(A_i \cap B) + \sum_{j \in J} b_j \mu(B_j \cap A) \quad (3.10.9)$$

$$= \sum_{i \in I} a_i \mu(A_i) + \sum_{j \in J} b_j \mu(B_j) = \int_S f d\mu + \int_S g d\mu \quad (3.10.10)$$

Note that all the terms are nonnegative (although some may be ∞), so there are no problems with rearranging the order of the terms.

2. This part is easier. For $c \in [0, \infty)$, recall that cf has the representation $cf = \sum_{i \in I} ca_i \mathbf{1}_{A_i}$ so

$$\int_S cf d\mu = \sum_{i \in I} ca_i \mu(A_i) = c \sum_{i \in I} a_i \mu(A_i) = c \int_S f d\mu \quad (3.10.11)$$

The [increasing property](#) holds for nonnegative simple functions.

Suppose that f and g are nonnegative simple functions and $f \leq g$ on S . Then $\int_S f d\mu \leq \int_S g d\mu$

Proof

The proof from the [additive property](#) above works. Note that $g-f$ is a nonnegative simple function, and $g = f + (g-f)$. By the additivity property, $\int_S g d\mu = \int_S f d\mu + \int_S (g-f) d\mu \geq \int_S f d\mu$.

Next we give a version of the continuity theorem in (7) for simple functions. It's not completely general, but will be needed for the next subsection where we do prove the general version.

Suppose that f is a nonnegative simple function and that (A_1, A_2, \dots) is an increasing sequence of sets in \mathcal{S} with $A = \bigcup_{n=1}^{\infty} A_n$. then

$$\int_S \mathbf{1}_{A_n} f d\mu \rightarrow \int_S \mathbf{1}_A f d\mu \text{ as } n \rightarrow \infty \quad (3.10.12)$$

Proof

Suppose that f has the representation $f = \sum_{i \in I} b_i \mathbf{1}_{B_i}$. Then $\mathbf{1}_{A_n} f = \sum_{i \in I} b_i \mathbf{1}_{A_n} \mathbf{1}_{B_i} = \sum_{i \in I} b_i \mathbf{1}_{A_n \cap B_i}$ and similarly, $\mathbf{1}_A f = \sum_{i \in I} b_i \mathbf{1}_{A \cap B_i}$. But for each $i \in I$, $B_i \cap A_n$ is increasing in $n \in \mathbb{N}_+$ and $\bigcup_{n=1}^{\infty} (B_i \cap A_n) = B_i \cap A$. By the continuity theorem for positive measures, $\mu(B_i \cap A_n) \rightarrow \mu(B_i \cap A)$ as $n \rightarrow \infty$ for each $i \in I$. Since I is finite,

$$\int_{A_n} f d\mu = \sum_{i \in I} b_i \mu(A_n \cap B_i) \rightarrow \sum_{i \in I} b_i \mu(A \cap B_i) = \int_A f d\mu \text{ as } n \rightarrow \infty \quad (3.10.13)$$

Note that $\mathbf{1}_{A_n} f$ is increasing in $n \in \mathbb{N}_+$ and $\mathbf{1}_{A_n} f \rightarrow \mathbf{1}_A f$ as $n \rightarrow \infty$, so this really is a special case of the monotone convergence theorem.

Nonnegative Functions

Next we will consider nonnegative measurable functions on S . First we note that a function of this type is the limit of nonnegative simple functions.

Suppose that $f : S \rightarrow [0, \infty)$ is measurable. Then there exists an increasing sequence (f_1, f_2, \dots) of nonnegative simple functions with $f_n \rightarrow f$ on S as $n \rightarrow \infty$.

Proof

For $n \in \mathbb{N}_+$ and $k \in \{1, 2, \dots, n2^n\}$ Let $I_{n,k} = [(k-1)/2^n, k/2^n)$ and $I_n = [n, \infty)$. Note that

1. $\{I_{n,k} : k = 1, \dots, n2^n\} \cup \{I_n\}$ is a partition of $[0, \infty)$ for each $n \in \mathbb{N}_+$.
2. $I_{n,k} = I_{n+1, 2k-1} \cup I_{n+1, 2k}$ for $k \in \{1, 2, \dots, n2^n\}$.
3. $I_n = \left(\bigcup_{k=n2^{n+1}+1}^{(n+1)2^{n+1}} I_{n+1, k} \right) \cup I_{n+1}$ for $n \in \mathbb{N}_+$.

Note that the n th partition divides the interval $[0, n)$ into $n2^n$ subintervals of length $1/2^n$. Thus, (b) follows because the $(n+1)$ st partition divides each of the first 2^n intervals of the n th partition in half, and (c) follows because the $(n+1)$ st partition divides the interval $[n, n+1)$ into subintervals of length $1/2^{n+1}$. Now let $A_{n,k} = f^{-1}(I_{n,k})$ and $A_n = f^{-1}(I_n)$ for $n \in \mathbb{N}_+$ and $k \in \{1, 2, \dots, n2^n\}$. Since inverse images preserve all set operations, (a), (b), and (c) hold with A replacing I everywhere, and S replacing $[0, \infty)$ in (a). Moreover, since f is measurable, $A_n \in \mathcal{S}$ and $A_{n,k} \in \mathcal{S}$ for each n and k . Now, define

$$f_n = \sum_{k=1}^{n2^n} \frac{k-1}{2^n} \mathbf{1}_{A_{n,k}} + n \mathbf{1}_{A_n} \quad (3.10.14)$$

Then f_n is a simple function and $0 \leq f_n \leq f$ for each $n \in \mathbb{N}_+$. To show convergence, fix $x \in S$. If $n > f(x)$ then $|f(x) - f_n(x)| \leq 2^{-n}$ and hence $f_n(x) \rightarrow f(x)$ as $n \rightarrow \infty$. All that remains is to show that f_n is increasing in n . Let $x \in S$ and $n \in \mathbb{N}_+$. If $x \in A_{n,k}$ for some $k \in \{1, 2, \dots, n2^n\}$, then $f_n(x) = (k-1)/2^n$. But either $f_{n+1}(x) = (2k-2)/2^{n+1}$ or $f_{n+1}(x) = (2k-1)/2^{n+1}$. If $x \in A_n$ then $f_n(x) = n$. But either $f_{n+1}(x) = (k-1)/2^{n+1}$ for some $k \in \{n2^{n+1}+1, \dots, (n+1)2^{n+1}\}$ or $f_{n+1}(x) = n+1$. In all cases, $f_{n+1}(x) \geq f_n(x)$.

The last result points the way towards the definition of the integral of a measurable function $f : S \rightarrow [0, \infty)$ in terms of the integrals of simple functions. If g is a nonnegative simple function with $g \leq f$, then by the [order property](#), we need $\int_S g d\mu \leq \int_S f d\mu$. On the other hand, there exists a sequence of nonnegative simple function converging to f . Thus the [continuity property](#) suggests the following definition:

If $f : S \rightarrow [0, \infty)$ is measurable, define

$$\int_S f d\mu = \sup \left\{ \int_S g d\mu : g \text{ is simple and } 0 \leq g \leq f \right\} \quad (3.10.15)$$

Note that $\int_S f d\mu$ exists in $[0, \infty]$ so the [positive property](#) holds. Note also that if f is simple, the new definition agrees with the old one. As always, we need to establish the essential properties. First, the [increasing property](#) holds.

If $f, g : S \rightarrow [0, \infty)$ are measurable and $f \leq g$ on S then $\int_S f d\mu \leq \int_S g d\mu$.

Proof

Note that $\{h : h \text{ is simple and } 0 \leq h \leq f\} \subseteq \{h : h \text{ is simple and } 0 \leq h \leq g\}$. therefore

$$\int_S f d\mu = \sup \left\{ \int_S h d\mu : h \text{ is simple and } 0 \leq h \leq f \right\} \leq \sup \left\{ \int_S h d\mu : h \text{ is simple and } 0 \leq h \leq g \right\} = \int_S g d\mu \quad (3.10.16)$$

We can now prove the [continuity property](#) known as the *monotone convergence theorem* in full generality.

Suppose that $f_n : S \rightarrow [0, \infty)$ is measurable for $n \in \mathbb{N}_+$ and that f_n is increasing in n . Then

$$\int_S \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu \quad (3.10.17)$$

Proof

Let $f = \lim_{n \rightarrow \infty} f_n$. By the order property, note that $\int_S f_n d\mu$ is increasing in $n \in \mathbb{N}_+$ and hence has a limit in \mathbb{R}^* , which we will denote by c . Note that $f_n \leq f$ on S for $n \in \mathbb{N}_+$, so by the order property again, $\int_S f_n d\mu \leq \int_S f d\mu$ for $n \in \mathbb{N}_+$. Letting $n \rightarrow \infty$ gives $c \leq \int_S f d\mu$. To show that $c \geq \int_S f d\mu$ we need to show that $c \geq \int_S g d\mu$ for every simple function g with $0 \leq g \leq f$. Fix $a \in (0, 1)$ and let $A_n = \{x \in S : f_n(x) \geq ag(x)\}$. Since f_n is increasing in n , $A_n \subseteq A_{n+1}$. Moreover, since $f_n \rightarrow f$ as $n \rightarrow \infty$ on S and $g \leq f$ on S , $\bigcup_{n=1}^{\infty} A_n = S$. But by definition, $ag \leq f_n$ on A_n so

$$\alpha \int_S \mathbf{1}_{A_n} g d\mu = \int_S \alpha \mathbf{1}_{A_n} g d\mu \leq \int_S \mathbf{1}_{A_n} f_n d\mu \leq \int_S f_n d\mu \quad (3.10.18)$$

Letting $n \rightarrow \infty$ in the extreme parts of the displayed inequality and using the version of the monotone convergence theorem for [simple functions](#), we have $a \int_S g d\mu \leq c$ for every $a \in (0, 1)$. Finally, letting $a \uparrow 1$ gives $\int_S g d\mu \leq c$

If $f : S \rightarrow [0, \infty)$ is measurable, then by the [theorem above](#), there exists an increasing sequence (f_1, f_2, \dots) of simple functions with $f_n \rightarrow f$ as $n \rightarrow \infty$. By the monotone convergence theorem in (18), $\int_S f_n d\mu \rightarrow \int_S f d\mu$ as $n \rightarrow \infty$. These two facts can be used to establish other properties of the integral of a nonnegative function based on our knowledge that the properties hold for simple functions. This type of argument is known as *bootstrapping*. We use bootstrapping to show that the [linearity properties](#) hold:

If $f, g : S \rightarrow [0, \infty)$ are measurable and $c \in [0, \infty)$, then

1. $\int_S (f + g) d\mu = \int_S f d\mu + \int_S g d\mu$
2. $\int_S cf d\mu = c \int_S f d\mu$

Proof

1. Let (f_1, f_2, \dots) and (g_1, g_2, \dots) be increasing sequences of nonnegative simple functions with $f_n \rightarrow f$ and $g_n \rightarrow g$ as $n \rightarrow \infty$. Then $(f_1 + g_1, f_2 + g_2, \dots)$ is also an increasing sequence of simple functions, and $f_n + g_n \rightarrow f + g$ as $n \rightarrow \infty$. By the monotone convergence theorem, $\int_S f_n d\mu \rightarrow \int_S f d\mu$, $\int_S g_n d\mu \rightarrow \int_S g d\mu$, and $\int_S (f_n + g_n) d\mu \rightarrow \int_S (f + g) d\mu$ as $n \rightarrow \infty$. But $\int_S (f_n + g_n) d\mu = \int_S f_n d\mu + \int_S g_n d\mu$ for each $n \in \mathbb{N}_+$ so taking limits gives $\int_S (f + g) d\mu = \int_S f d\mu + \int_S g d\mu$.
2. Similarly, (cf_1, cf_2, \dots) is an increasing sequence of nonnegative simple functions with $cf_n \rightarrow cf$ as $n \rightarrow \infty$. Again, by the MCT, $\int_S cf_n d\mu \rightarrow \int_S cf d\mu$ and $\int_S cf_n d\mu = c \int_S f_n d\mu$ so taking limits gives $\int_S cf d\mu = c \int_S f d\mu$.

General Functions

Our final step is to define the integral of a measurable function $f : S \rightarrow \mathbb{R}$. First, recall the positive and negative parts of $x \in \mathbb{R}$:

$$x^+ = \max\{x, 0\}, \quad x^- = \max\{-x, 0\} \quad (3.10.19)$$

Note that $x^+ \geq 0$, $x^- \geq 0$, $x = x^+ - x^-$, and $|x| = x^+ + x^-$. Given that we want the integral to have the linearity properties in (5), there is no question as to how we should define the integral of f in terms of the integrals of f^+ and f^- , which being nonnegative, are defined by the previous subsection.

If $f : S \rightarrow \mathbb{R}$ is measurable, we define

$$\int_S f d\mu = \int_S f^+ d\mu - \int_S f^- d\mu \quad (3.10.20)$$

assuming that at least one of the integrals on the right is finite. If both are finite, then f is said to be *integrable*.

Assuming that either the integral of the positive part or the integral of the negative part is finite ensures that we do not get the dreaded indeterminate form $\infty - \infty$.

Suppose that $f : S \rightarrow \mathbb{R}$ is measurable. Then f is integrable if and only if $\int_S |f| d\mu < \infty$.

Proof

Suppose that f is integrable. Recall that $|f| = f^+ + f^-$. By the additive property for nonnegative functions, $\int_S |f| d\mu = \int_S f^+ d\mu + \int_S f^- d\mu < \infty$. Conversely, suppose that $\int_S |f| d\mu < \infty$. Then $f^+ \leq |f|$ and $f^- \leq |f|$ so by the increasing property for nonnegative functions, $\int_S f^+ d\mu \leq \int_S |f| d\mu < \infty$ and $\int_S f^- d\mu \leq \int_S |f| d\mu < \infty$.

Note that if f is nonnegative, then our new definition agrees with our old one, since $f^+ = f$ and $f^- = 0$. For simple functions the integral has the same basic form as for nonnegative simple functions:

Suppose that f is a simple function with the representation $f = \sum_{i \in I} a_i \mathbf{1}_{A_i}$. Then

$$\int_S f d\mu = \sum_{i \in I} a_i \mu(A_i) \quad (3.10.21)$$

assuming that the sum does not have both ∞ and $-\infty$ terms.

Proof

Note that f^+ and f^- are also simple, with the representations $f^+ = \sum_{i \in I} a_i^+ \mathbf{1}_{A_i}$ and $f^- = \sum_{i \in I} a_i^- \mathbf{1}_{A_i}$. Hence

$$\int_S f d\mu = \sum_{i \in I} a_i^+ \mu(A_i) - \sum_{i \in I} a_i^- \mu(A_i) \quad (3.10.22)$$

as long as one of the sums is finite. Given that this is the case, we can recombine the sums to get

$$\int_S f d\mu = \sum_{i \in I} a_i \mu(A_i) \quad (3.10.23)$$

Once again, we need to establish the essential properties. Our first result is an intermediate step towards linearity.

If $f, g: S \rightarrow [0, \infty)$ are measurable then $\int_S (f - g) d\mu = \int_S f d\mu - \int_S g d\mu$ as long as at least one of the integrals on the right is finite.

Proof

We take cases. Suppose first that $\int_S f d\mu < \infty$ and $\int_S g d\mu < \infty$. Note that $(f - g)^+ \leq f$ and $(f - g)^- \leq g$. By the increasing property for nonnegative functions, $\int_S (f - g)^+ d\mu \leq \int_S f d\mu < \infty$ and $\int_S (f - g)^- d\mu \leq \int_S g d\mu < \infty$. Thus $f - g$ is integrable. Next we have $f - g = (f - g)^+ - (f - g)^-$ and therefore $f + (f - g)^- = g + (f - g)^+$. All four of the functions in the last equation are nonnegative, and therefore by additivity property for nonnegative functions, we have

$$\int_S f d\mu + \int_S (f - g)^- d\mu = \int_S g d\mu + \int_S (f - g)^+ d\mu \quad (3.10.24)$$

All of these integrals are finite, and hence

$$\int_S (f - g) d\mu = \int_S (f - g)^+ d\mu - \int_S (f - g)^- d\mu = \int_S f d\mu - \int_S g d\mu \quad (3.10.25)$$

Next suppose that $\int_S f d\mu = \infty$ and $\int_S g d\mu < \infty$. Then $f - g \leq (f - g)^+$ and hence $f \leq (f - g)^+ + g$. Using the additivity and increasing properties for nonnegative functions, we have $\infty = \int_S f d\mu \leq \int_S (f - g)^+ d\mu + \int_S g d\mu$. Since $\int_S g d\mu < \infty$ we must have $\int_S (f - g)^+ d\mu = \infty$. On the other hand, $(f - g)^- \leq g$ so $\int_S (f - g)^- d\mu \leq \int_S g d\mu < \infty$. Hence $\int_S (f - g) d\mu = \infty = \int_S f d\mu - \int_S g d\mu$.

Finally, suppose that $\int_S f d\mu < \infty$ and $\int_S g d\mu = \infty$. By the argument in the last paragraph, we have $\int_S (g - f)^+ d\mu = \infty$ and $\int_S (g - f)^- d\mu < \infty$. Equivalently, $\int_S (f - g)^+ d\mu < \infty$ and $\int_S (f - g)^- d\mu = \infty$. Hence $\int_S (f - g) d\mu = -\infty = \int_S f d\mu - \int_S g d\mu$.

We finally have the [linearity properties](#) in full generality.

If $f, g: S \rightarrow \mathbb{R}$ are measurable functions whose integrals exist, and $c \in \mathbb{R}$, then

1. $\int_S (f + g) d\mu = \int_S f d\mu + \int_S g d\mu$ as long as the right side is not of the form $\infty - \infty$.
2. $\int_S cf d\mu = c \int_S f d\mu$

Proof

1. Note that $f + g = (f^+ - f^-) + (g^+ - g^-) = (f^+ + g^+) - (f^- + g^-)$ and the two functions in parentheses in the last expression are nonnegative. By the previous lemma and the additivity property for nonnegative functions, we have

$$\int_S (f + g) d\mu = \int_S (f^+ + g^+) d\mu - \int_S (f^- + g^-) d\mu \quad (3.10.26)$$

$$= \left(\int_S f^+ d\mu + \int_S g^+ d\mu \right) - \left(\int_S f^- d\mu + \int_S g^- d\mu \right) \quad (3.10.27)$$

assuming that either both integrals in the first parentheses are finite or both integrals in the second parentheses are finite. In either case, we can group the terms (without worrying about the dreaded $\infty - \infty$) to get

$$\int_S (f+g) d\mu = \left(\int_S f^+ d\mu - \int_S f^- d\mu \right) + \left(\int_S g^+ d\mu - \int_S g^- d\mu \right) = \int_S f d\mu + \int_S g d\mu \quad (3.10.28)$$

2. Note that if $c \geq 0$ then $(cf)^+ = cf^+$ and $(cf)^- = cf^-$. Hence using the scaling property for nonnegative functions,

$$\int_S cf d\mu = \int_S (cf)^+ d\mu - \int_S (cf)^- d\mu = \int_S cf^+ d\mu - \int_S cf^- d\mu = c \int_S f^+ d\mu - c \int_S f^- d\mu = c \int_S f d\mu \quad (3.10.29)$$

On the other hand, if $c < 0$, $(cf)^+ = -cf^-$ and $(cf)^- = -cf^+$. Again using the scaling property for nonnegative functions,

$$\int_S cf d\mu = \int_S (cf)^+ d\mu - \int_S (cf)^- d\mu = \int_S -cf^- d\mu - \int_S -cf^+ d\mu = -c \int_S f^- d\mu + c \int_S f^+ d\mu = c \int_S f d\mu \quad (3.10.30)$$

In particular, note that if f and g are integrable, then so are $f+g$ and cf for $c \in \mathbb{R}$. Thus, the set of integrable functions on (S, \mathcal{S}, μ) forms a vector space, which is denoted $\mathcal{L}(S, \mathcal{S}, \mu)$. The \mathcal{L} is in honor of Henri Lebesgue, who first developed the theory. This vector space, and other related ones, will be studied in more detail in the section on function spaces.

We also have the [increasing property](#) in full generality.

If $f, g : S \rightarrow \mathbb{R}$ are measurable functions whose integrals exist, and if $f \leq g$ on S then $\int_S f d\mu \leq \int_S g d\mu$

Proof

We can use the proof based on the additive property from (6). First $g = f + (g - f)$ and $g - f \geq 0$ on S . If $\int_S f d\mu = -\infty$ then trivially, $\int_S f d\mu \leq \int_S g d\mu$. Otherwise $\int_S (g - f) d\mu \geq 0$ and therefore $\int_S g d\mu = \int_S f d\mu + \int_S (g - f) d\mu \geq \int_S f d\mu$.

The Integral Over a Set

Now that we have defined the integral of a measurable function f over all of S , there is a natural extension to the integral of f over a measurable subset

If $f : S \rightarrow \mathbb{R}$ is measurable and $A \in \mathcal{S}$, we define

$$\int_A f d\mu = \int_S \mathbf{1}_A f d\mu \quad (3.10.31)$$

assuming that the integral on the right exists.

If $f : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists and $A \in \mathcal{S}$, then the integral of f over A exists.

Proof

Note that $(\mathbf{1}_A f)^+ = \mathbf{1}_A f^+$ and $(\mathbf{1}_A f)^- = \mathbf{1}_A f^-$. Also $\mathbf{1}_A f^+ \leq f^+$ and $\mathbf{1}_A f^- \leq f^-$. If $\int_S f d\mu$ exists, then either $\int_S f^+ d\mu < \infty$ or $\int_S f^- d\mu < \infty$. By the increasing property, it follows that either $\int_S \mathbf{1}_A f^+ d\mu < \infty$ or $\int_S \mathbf{1}_A f^- d\mu < \infty$, so $\int_A f d\mu$ exists.

On the other hand, it's clearly possible for $\int_A f d\mu$ to exist for some $A \in \mathcal{S}$, but not $\int_S f d\mu$.

We could also simply think of $\int_A f d\mu$ as the integral of a measurable function $f : A \rightarrow \mathbb{R}$ over the measure space $(A, \mathcal{S}_A, \mu_A)$, where $\mathcal{S}_A = \{B \in \mathcal{S} : B \subseteq A\} = \{C \cap A : C \in \mathcal{S}\}$ is the σ -algebra of measurable subsets of A , and where μ_A is the restriction of μ to \mathcal{S}_A . It follows that all of the essential properties hold for integrals over A : the [linearity properties](#), the [order properties](#), and the [monotone convergence theorem](#). The following property is a simple consequence of the general additive property, and is known as *additive property for disjoint domains*.

Suppose that $f : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists, and that $A, B \in \mathcal{S}$ are disjoint. then

$$\int_{A \cup B} f d\mu = \int_A f d\mu + \int_B f d\mu \quad (3.10.32)$$

Proof

Recall that $\mathbf{1}_{A \cup B} = \mathbf{1}_A + \mathbf{1}_B$. Hence by the additive property and the previous result,

$$\int_{A \cup B} f d\mu = \int_S \mathbf{1}_{A \cup B} f d\mu = \int_S (\mathbf{1}_A f + \mathbf{1}_B f) d\mu = \int_S \mathbf{1}_A f d\mu + \int_S \mathbf{1}_B f d\mu = \int_A f d\mu + \int_B f d\mu \quad (3.10.33)$$

By induction, the additive property holds for a finite collection of disjoint domains. The extension to a countably infinite collection of disjoint domains will be considered in the next section on properties of the integral.

Special Cases

Discrete Spaces

Recall again that the measure space $(S, \mathcal{S}, \#)$ is *discrete* if S is countable, \mathcal{S} is the collection of all subsets of S , and $\#$ is counting measure on \mathcal{S} . Thus all functions $f : S \rightarrow \mathbb{R}$ are measurable, and as we will see, integrals with respect to $\#$ are simply sums.

If $f : S \rightarrow \mathbb{R}$ then

$$\int_S f d\# = \sum_{x \in S} f(x) \quad (3.10.34)$$

as long as either the sum of the positive terms or the sum of the negative terms is finite.

Proof

The proof is a bootstrapping argument.

1. Suppose first that S is finite. In this case, every function $f : S \rightarrow \mathbb{R}$ is simple and has the representation $f = \sum_{x \in S} f(x) \mathbf{1}_x$ where $\mathbf{1}_x$ is an abbreviation of $\mathbf{1}_{\{x\}}$. Thus the result follows from the definition of the integral.
2. Next suppose that S is countable infinite and $f : S \rightarrow [0, \infty)$. Let (A_1, A_2, \dots) be an increasing sequence of finite subsets of S with $\bigcup_{i=1}^{\infty} A_i = S$. Define $f_n = \sum_{x \in A_n} f(x) \mathbf{1}_x$. Then (f_1, f_2, \dots) is an increasing sequence of simple functions with $f_n \rightarrow f$ as $n \rightarrow \infty$. Thus

$$\int_S f d\# = \lim_{n \rightarrow \infty} \int_S f_n d\# = \lim_{n \rightarrow \infty} \sum_{x \in A_n} f(x) \quad (3.10.35)$$

But by definition, the last limit on the right is just $\sum_{x \in S} f(x)$.

3. Finally consider the general case where S is countable and $f : S \rightarrow \mathbb{R}$. In this case the result follows from the definition of the integral as $\int_S f d\# = \int_S f^+ d\# - \int_S f^- d\#$ as long as one of the integrals on the right is finite. By (b), $\int_S f^+ d\#$ is the sum of the positive terms and $-\int_S f^- d\#$ is the sum of the negative terms.

If the sum of the positive terms and the sum of the negative terms are both finite, then f is integrable with respect to $\#$, but the usual term from calculus is that the series $\sum_{x \in S} f(x)$ is *absolutely convergent*. The result will look more familiar in the special case $S = \mathbb{N}_+$. Functions on S are simply sequences, so we can use the more familiar notation a_i rather than $a(i)$ for a function $a : S \rightarrow \mathbb{R}$. Part (b) of the proof (with $A_n = \{1, 2, \dots, n\}$) is just the definition of an infinite series of nonnegative terms as the limit of the partial sums:

$$\sum_{i=1}^{\infty} a_i = \lim_{n \rightarrow \infty} \sum_{i=1}^n a_i \quad (3.10.36)$$

Part (c) of the proof is just the definition of a general infinite series

$$\sum_{i=1}^{\infty} a_i = \sum_{i=1}^{\infty} a_i^+ - \sum_{i=1}^{\infty} a_i^- \quad (3.10.37)$$

as long as one of the series on the right is finite. Again, when both are finite, the series is absolutely convergent. In calculus we also consider *conditionally convergent* series. This means that $\sum_{i=1}^{\infty} a_i^+ = \infty$, $\sum_{i=1}^{\infty} a_i^- = \infty$, but $\lim_{n \rightarrow \infty} \sum_{i=1}^n a_i$ exists in \mathbb{R} . Such series have no place in general integration theory. Also, you may recall that such series are pathological in the sense that, given any number in \mathbb{R}^* , there exists a rearrangement of the terms so that the rearranged series converges to the given number.

The Lebesgue and Riemann Integrals on \mathbb{R}

Consider the one-dimensional Euclidean space $(\mathbb{R}, \mathcal{R}, \lambda)$ where \mathcal{R} is the usual σ -algebra of Lebesgue measurable sets and λ is Lebesgue measure. The theory developed above applies, of course, for the integral $\int_A f d\mu$ of a measurable function $f : \mathbb{R} \rightarrow \mathbb{R}$ over a set $A \in \mathcal{R}$. It's not surprising that in this special case, the theory of integration is referred to as *Lebesgue integration* in honor of our good friend Henri Lebesgue, who first developed the theory.

On the other hand, we already have a theory of integration on \mathbb{R} , namely the Riemann integral of calculus, named for our other good friend Georg Riemann. For a suitable function f and domain A this integral is denoted $\int_A f(x) dx$, as we all remember from calculus. How are the two integrals related? As we will see, the Lebesgue integral generalizes the Riemann integral.

To understand the connection we need to review the definition of the Riemann integral. Consider first the standard case where the domain of integration is a closed, bounded interval. Here are the preliminary definitions that we will need.

Suppose that $f : [a, b] \rightarrow \mathbb{R}$, where $a, b \in \mathbb{R}$ and $a < b$.

1. A *partition* $\mathcal{A} = \{A_i : i \in I\}$ of $[a, b]$ is a finite collection of disjoint *subintervals* whose union is $[a, b]$.

2. The *norm* of a partition \mathcal{A} is $\|\mathcal{A}\| = \max\{\lambda(A_i) : i \in I\}$, the length of the largest subinterval of \mathcal{A} .
3. A set of points $B = \{x_i : i \in I\}$ where $x_i \in A_i$ for each $i \in I$ is said to be *associated* with the partition \mathcal{A} .
4. The *Riemann sum* of f corresponding to a partition \mathcal{A} and a set B associated with \mathcal{A} is

$$R(f, \mathcal{A}, B) = \sum_{i \in I} f(x_i) \lambda(A_i) \quad (3.10.38)$$

Note that the Riemann sum is simply the integral of the simple function $g = \sum_{i \in I} f(x_i) \mathbf{1}_{A_i}$. Moreover, since A_i is an interval for each $i \in I$, g is a *step function*, since it is constant on a finite collection of disjoint intervals. Moreover, again since A_i is an interval for each $i \in I$, $\lambda(A_i)$ is simply the length of the subinterval A_i , so of course measure theory per se is not needed for Riemann integration. Now for the definition from calculus:

f is *Riemann integrable* on $[a, b]$ if there exists $r \in \mathbb{R}$ with the property that for every $\epsilon > 0$ there exists $\delta > 0$ such that if \mathcal{A} is a partition of $[a, b]$ with $\|\mathcal{A}\| < \delta$ then $|r - R(f, \mathcal{A}, B)| < \epsilon$ for every set of points B associated with \mathcal{A} . Then of course we define the integral by

$$\int_a^b f(x) dx = r \quad (3.10.39)$$

Here is our main theorem of this subsection.

If $f : [a, b] \rightarrow \mathbb{R}$ is Riemann integrable on $[a, b]$ then f is Lebesgue integrable on $[a, b]$ and

$$\int_{[a,b]} f d\lambda = \int_a^b f(x) dx \quad (3.10.40)$$

On the other hand, there are lots of functions that are Lebesgue integrable but not Riemann integrable. In fact there are indicator functions of this type, the simplest of functions from the point of view of Lebesgue integration.

Consider the function $\mathbf{1}_{\mathbb{Q}}$ where as usual, \mathbb{Q} is the set of rational number in \mathbb{R} . Then

1. $\int_{\mathbb{R}} \mathbf{1}_{\mathbb{Q}} d\lambda = 0$.
2. $\mathbf{1}_{\mathbb{Q}}$ is not Riemann integrable on any interval $[a, b]$ with $a < b$.

Proof

Part (a) follows from the definition of the Lebesgue integral:

$$\int_{\mathbb{R}} \mathbf{1}_{\mathbb{Q}} d\lambda = \lambda(\mathbb{Q}) = 0 \quad (3.10.41)$$

For part (b), note that there are rational and irrational numbers in every interval of \mathbb{R} of positive length (the rational numbers and the irrational numbers are *dense* in \mathbb{R}). Thus, given any partition $\mathcal{A} = \{A_i : i \in I\}$ of $[a, b]$, no matter how small the norm, there are Riemann sums that are 0 (take $x_i \in A_i$ irrational for each $i \in I$), and Riemann sums that are $b - a$ (take $x_i \in A_i$ rational for each $i \in I$).

The following fundamental theorem completes the picture.

$f : [a, b] \rightarrow \mathbb{R}$ is Riemann integrable on $[a, b]$ if and only if f is bounded on $[a, b]$ and f is continuous almost everywhere on $[a, b]$.

Now that the Riemann integral is defined for a closed bounded interval, it can be extended to other domains.

Extensions of the Riemann integral.

1. If f is defined on $[a, b)$ and Riemann integrable on $[a, t]$ for $a < t < b$, we define $\int_a^b f(x) dx = \lim_{t \uparrow b} \int_a^t f(x) dx$ if the limit exists in \mathbb{R}^* .
2. If f is defined on $(a, b]$ and Riemann integrable on $[t, b]$ for $a < t < b$, we define $\int_a^b f(x) dx = \lim_{t \downarrow a} \int_t^b f(x) dx$ if the limit exists in \mathbb{R}^* .
3. If f is defined on (a, b) , we select $c \in (a, b)$ and define $\int_a^b f(x) dx = \int_a^c f(x) dx + \int_c^b f(x) dx$ if the integrals on the right exist in \mathbb{R}^* by (a) and (b), and are not of the form $\infty - \infty$.
4. If f is defined on $[a, \infty)$ and Riemann integrable on $[a, t]$ for $a < t < \infty$ we define $\int_a^\infty f(x) dx = \lim_{t \rightarrow \infty} \int_a^t f(x) dx$.
5. If f is defined on $(-\infty, b]$ and Riemann integrable on $[t, b]$ for $-\infty < t < b$ we define $\int_{-\infty}^b f(x) dx = \lim_{t \rightarrow -\infty} \int_t^b f(x) dx$ if the limit exists in \mathbb{R}^* .
6. If f is defined on \mathbb{R} we select $c \in \mathbb{R}$ and define $\int_{-\infty}^\infty f(x) dx = \int_{-\infty}^c f(x) dx + \int_c^\infty f(x) dx$ if both integrals on the right exist by (d) and (e), and are not of the form $\infty - \infty$.

7. The integral is defined for a domain that is the union of a finite collection of disjoint intervals by the requirement that the integral be additive over disjoint domains

As another indication of its superiority, note that *none* of these convolutions is necessary for the Lebesgue integral. Once and for all, we have defined $\int_A f(x) dx$ for a general measurable function $f : \mathbb{R} \rightarrow \mathbb{R}$ and a general domain $A \in \mathcal{R}$

The Lebesgue-Stieltjes Integral

Consider again the measurable space $(\mathbb{R}, \mathcal{R})$ where \mathcal{R} is the usual σ -algebra of Lebesgue measurable subsets of \mathbb{R} . Suppose that $F : \mathbb{R} \rightarrow \mathbb{R}$ is a general distribution function, so that by definition, F is increasing and continuous from the right. Recall that the Lebesgue-Stieltjes measure μ associated with F is the unique measure on \mathcal{R} that satisfies

$$\mu(a, b] = F(b) - F(a); \quad a, b \in \mathbb{R}, \quad a < b \quad (3.10.42)$$

Recall that F satisfies some, but not necessarily all of the properties of a probability distribution function. The properties not necessarily satisfied are the normalizing properties

- $F(x) \rightarrow 0$ as $x \rightarrow -\infty$
- $F(x) \rightarrow 1$ as $x \rightarrow \infty$

If F does satisfy these two additional properties, then μ is a probability measure and F its probability distribution function.

The integral with respect to the measure μ is, appropriately enough, referred to as the *Lebesgue-Stieltjes* integral with respect to F , and like the measure, is named for the ubiquitous Henri Lebesgue and for Thomas Stieltjes. In addition to our usual notation $\int_S f d\mu$, the Lebesgue-Stieltjes integral is also denoted $\int_S f dF$ and $\int_S f(x) dF(x)$.

Probability Spaces

Suppose that $(S, \mathcal{S}, \mathbb{P})$ is a probability space, so that S is the set of outcomes of a random experiment, \mathcal{S} is the σ -algebra of events, and \mathbb{P} the probability measure on the sample space (S, \mathcal{S}) . A measurable, real-valued function X on S is, of course, a real-valued random variable. The integral with respect to \mathbb{P} , if it exists, is the *expected value* of X and is denoted

$$\mathbb{E}(X) = \int_S X d\mathbb{P} \quad (3.10.43)$$

This concept is of fundamental importance in probability theory and is studied in detail in a separate chapter on Expected Value, mostly from an elementary point of view that does not involve abstract integration. However an advanced section treats expected value as an integral over the underlying probability measure, as above.

Suppose next that $(T, \mathcal{T}, \#)$ is a discrete space and that X is a random variable for the experiment, taking values in T . In this case X has a discrete distribution and the probability density function f of X is given by $f(x) = \mathbb{P}(X = x)$ for $x \in T$. More generally,

$$\mathbb{P}(X \in A) = \sum_{x \in A} f(x) = \int_A f d\#, \quad A \subseteq T \quad (3.10.44)$$

On the other hand, suppose that X is a random variable with values in \mathbb{R}^n , where as usual, $(\mathbb{R}^n, \mathcal{R}_n, \lambda_n)$ is n -dimensional Euclidean space. If X has a continuous distribution, then $f : T \rightarrow [0, \infty)$ is a probability density function of X if

$$\mathbb{P}(X \in A) = \int_A f d\lambda_n, \quad A \in \mathcal{R}^n \quad (3.10.45)$$

Technically, f is the density function of X with respect to counting measure $\#$ in the discrete case, and f is the density function of X with respect to Lebesgue measure λ_n in the continuous case. In both cases, the probability of an event A is computed by integrating the density function, with respect to the appropriate measure, over A . There are still differences, however. In the discrete case, the existence of the density function with respect to counting measure is guaranteed, and indeed we have an explicit formula for it. In the continuous case, the existence of a density function with respect to Lebesgue measure is not guaranteed, and indeed there might not be one. More generally, suppose that we have a measure space (T, \mathcal{T}, μ) and a random variable X with values in T . A measurable function $f : T \rightarrow [0, \infty)$ is a *probability density function* of X (or more precisely, the *distribution* of X) with respect to μ if

$$\mathbb{P}(X \in A) = \int_A f d\mu, \quad A \in \mathcal{T} \quad (3.10.46)$$

This fundamental question of the existence of a density function will be clarified in the section on absolute continuity and density functions.

Suppose again that X is a real-valued random variable with distribution function F . Then, by definition, the distribution of X is the Lebesgue-Stieltjes measure associated with F :

$$\mathbb{P}(a < X \leq b) = F(b) - F(a), \quad a, b \in \mathbb{R}, \quad a < b \quad (3.10.47)$$

regardless of whether the distribution is discrete, continuous, or mixed. Trivially, $\mathbb{P}(X \in A) = \int_S \mathbf{1}_A dF$ for $A \in \mathcal{R}$ and the expected value of X defined above can also be written as $\mathbb{E}(X) = \int_{\mathbb{R}} x dF(x)$. Again, all of this will be explained in much more detail in the next chapter on Expected Value.

Computational Exercises

Let $g(x) = \frac{1}{1+x^2}$ for $x \in \mathbb{R}$.

1. Find $\int_{-\infty}^{\infty} g(x) dx$.
2. Show that $\int_{-\infty}^{\infty} xg(x) dx$ does not exist.

Answer

1. $\int_{-\infty}^{\infty} g(x) dx = \pi$
2. $\int_0^{\infty} xg(x) dx = \infty$, $\int_{-\infty}^0 xg(x) dx = -\infty$

You may recall that the function g in the last exercise is important in the study of the *Cauchy distribution*, named for Augustin Cauchy. You may also remember that the graph of g is known as the *witch of Agnesi*, named for Maria Agnesi.

Let $g(x) = \frac{1}{x^b}$ for $x \in [1, \infty)$ where $b > 0$ is a parameter. Find $\int_1^{\infty} g(x) dx$

Answer

$$\int_1^{\infty} g(x) dx = \begin{cases} \infty, & 0 < b \leq 1 \\ \frac{1}{b-1}, & b > 1 \end{cases}$$

You may recall that the function g in the last exercise is important in the study of the *Pareto distribution*, named for Vilfredo Pareto.

Suppose that $f(x) = 0$ if $x \in \mathbb{Q}$ and $f(x) = \sin(x)$ if $x \in \mathbb{R} - \mathbb{Q}$.

1. Find $\int_{[0, \pi]} f(x) d\lambda(x)$
2. Does $\int_0^{\pi} f(x) dx$ exist?

Answer

1. 2
2. No

This page titled [3.10: The Integral With Respect to a Measure](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

3.11: Properties of the Integral

Basic Theory

Again our starting point is a measure space (S, \mathcal{S}, μ) . That is, S is a set, \mathcal{S} is a σ -algebra of subsets of S , and μ is a positive measure on \mathcal{S} .

Definition

In the last section we defined the integral of certain measurable functions $f : S \rightarrow \mathbb{R}$ with respect to the measure μ . Recall that the integral, denoted $\int_S f d\mu$, may exist as a number in \mathbb{R} (in which case f is *integrable*), or may exist as ∞ or $-\infty$, or may fail to exist. Here is a review of how the definition is built up in stages:

Definition of the integral

1. If f is a nonnegative simple function, so that $f = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ where I is a finite index set, $a_i \in [0, \infty)$ for $i \in I$, and $\{A_i : i \in I\}$ is measurable partition of S , then

$$\int_S f d\mu = \sum_{i \in I} a_i \mu(A_i) \quad (3.11.1)$$

2. If $f : S \rightarrow [0, \infty)$ is measurable, then

$$\int_S f d\mu = \sup \left\{ \int_S g d\mu : g \text{ is simple and } 0 \leq g \leq f \right\} \quad (3.11.2)$$

3. If $f : S \rightarrow \mathbb{R}$ is measurable, then

$$\int_S f d\mu = \int_S f^+ d\mu - \int_S f^- d\mu \quad (3.11.3)$$

as long as the right side is not of the form $\infty - \infty$, and where f^+ and f^- denote the positive and negative parts of f .

4. If $f : S \rightarrow \mathbb{R}$ is measurable and $A \in \mathcal{S}$, then the integral of f over A is defined by

$$\int_A f d\mu = \int_S \mathbf{1}_A f d\mu \quad (3.11.4)$$

assuming that the integral on the right exists.

Consider a statement on the elements of S , for example an equation or an inequality with $x \in S$ as a free variable. (Technically such a statement is a *predicate* on S .) For $A \in \mathcal{S}$, we say that the statement holds *on* A if it is true for every $x \in A$. We say that the statement holds *almost everywhere on* A (with respect to μ) if there exists $B \in \mathcal{S}$ with $B \subseteq A$ such that the statement holds on B and $\mu(A \setminus B) = 0$.

Basic Properties

A few properties of the integral that were essential to the motivation of the definition were given in the last section. In this section, we extend some of those properties and we study a number of new ones. As a review, here is what we know so far.

Properties of the integral

1. If $f, g : S \rightarrow \mathbb{R}$ are measurable functions whose integrals exist, then $\int_S (f + g) d\mu = \int_S f d\mu + \int_S g d\mu$ as long as the right side is not of the form $\infty - \infty$.
2. If $f : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists and $c \in \mathbb{R}$, then $\int_S cf d\mu = c \int_S f d\mu$.
3. If $f : S \rightarrow \mathbb{R}$ is measurable and $f \geq 0$ on S then $\int_S f d\mu \geq 0$.
4. If $f, g : S \rightarrow \mathbb{R}$ are measurable functions whose integrals exist and $f \leq g$ on S then $\int_S f d\mu \leq \int_S g d\mu$.
5. If $f_n : S \rightarrow [0, \infty)$ is measurable for $n \in \mathbb{N}_+$ and f_n is increasing in n on S then $\int_S \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu$.
6. $f : S \rightarrow \mathbb{R}$ is measurable and the the integral of f on $A \cup B$ exists, where $A, B \in \mathcal{S}$ are disjoint, then $\int_{A \cup B} f d\mu = \int_A f d\mu + \int_B f d\mu$.

Parts (a) and (b) are the *linearity properties*; part (a) is the *additivity property* and part (b) is the *scaling property*. Parts (c) and (d) are the *order properties*; part (c) is the *positive property* and part (d) is the *increasing property*. Part (e) is a continuity property known as the *monotone convergence theorem*. Part (f) is the *additive property for disjoint domains*. Properties (a)–(e) hold with S replaced by $A \in \mathcal{S}$.

Equality and Order

Our first new results are extensions dealing with equality and order. The integral of a function over a null set is 0:

Suppose that $f : S \rightarrow \mathbb{R}$ is measurable and $A \in \mathcal{S}$ with $\mu(A) = 0$. Then $\int_A f d\mu = 0$.

Proof

The proof proceeds in stages via the definition of the integral.

1. Suppose that g is a nonnegative simple function with $g = 0$ on A^c . Then g has the representation $g = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ where $a_i \in (0, \infty)$ and $A_i \subseteq A$ for $i \in I$. But $\mu(A_i) = 0$ for each $i \in I$ and so $\int_S g d\mu = \sum_{i \in I} a_i \mu(A_i) = 0$.
2. Suppose that $f : S \rightarrow [0, \infty)$ is measurable. If g is a nonnegative simple function with $g \leq \mathbf{1}_A f$, then $g = 0$ on A^c so by (a), $\int_S g d\mu = 0$. Hence by part (b) of (1), $\int_A f d\mu = \int_S \mathbf{1}_A f d\mu = 0$.
3. Finally, suppose that $f : S \rightarrow \mathbb{R}$ is measurable. Then $\int_A f d\mu = \int_A f^+ d\mu - \int_A f^- d\mu$. But both integrals on the right are 0 by part (b).

Two functions that are indistinguishable from the point of view of μ must have the same integral.

Suppose that $f : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists. If $g : S \rightarrow \mathbb{R}$ is measurable and $g = f$ almost everywhere on S , then $\int_S g d\mu = \int_S f d\mu$.

Proof

Note that $g = f$ if and only if $g^+ = f^+$ and $g^- = f^-$. Let $A = \{x \in S : g^+(x) = f^+(x)\}$. Then $A \in \mathcal{S}$ and $\mu(A^c) = 0$. Hence by the additivity property and (3),

$$\int_S g^+ d\mu = \int_A g^+ d\mu + \int_{A^c} g^+ d\mu = \int_A f^+ d\mu + 0 = \int_A f^+ d\mu + \int_{A^c} f^+ d\mu = \int_S f^+ d\mu \quad (3.11.5)$$

Similarly $\int_S g^- d\mu = \int_S f^- d\mu$. Hence the integral of g exists and $\int_S g d\mu = \int_S f d\mu$.

Next we have a simple extension of the positive property.

Suppose that $f : S \rightarrow \mathbb{R}$ is measurable and $f \geq 0$ almost everywhere on S . Then

1. $\int_S f d\mu \geq 0$
2. $\int_S f = 0$ if and only if $f = 0$ almost everywhere on S .

Proof

1. Let $A = \{x \in S : f(x) \geq 0\}$. Then $A \in \mathcal{S}$ and $\mu(A^c) = 0$. By the additivity of the integral over disjoint sets we have

$$\int_S f d\mu = \int_A f d\mu + \int_{A^c} f d\mu \quad (3.11.6)$$

But $\int_A f d\mu \geq 0$ by the [positive property](#) and $\int_{A^c} f d\mu = 0$ by the [null property](#), so $\int_S f d\mu \geq 0$.

2. Note first that if $\mu(A) = 0$ then both integrals in the displayed equation are 0 so $\int_S f d\mu = 0$. For the converse, let $B_n = \{x \in S : f(x) \geq \frac{1}{n}\}$ for $n \in \mathbb{N}_+$ and $B = \{x \in S : f(x) > 0\}$. Then B_n is increasing in n and $\bigcup_{n=1}^{\infty} B_n = B$. If $\mu(B) > 0$ then $\mu(B_n) > 0$ for some $n \in \mathbb{N}_+$. But $f \geq \frac{1}{n} \mathbf{1}_{B_n}$ on A , so by the increasing property, $\int_S f d\mu = \int_A f d\mu \geq \int_A \frac{1}{n} \mathbf{1}_{B_n} d\mu = \frac{1}{n} \mu(B_n) > 0$.

So, if $f \geq 0$ almost everywhere on S then $\int_S f d\mu > 0$ if and only if $\mu\{x \in S : f(x) > 0\} > 0$. The simple extension of the positive property in turn leads to a simple extension of the increasing property.

Suppose that $f, g : S \rightarrow \mathbb{R}$ are measurable functions whose integrals exist, and that $f \leq g$ almost everywhere on S . Then

1. $\int_S f \leq \int_S g$

2. Except in the case that both integrals are ∞ or both $-\infty$, $\int_S f d\mu = \int_S g d\mu$ if and only if $f = g$ almost everywhere on S .

Proof

1. Note that $g = f + (g - f)$ and $g - f \geq 0$ almost everywhere on S . If $\int_S f d\mu = -\infty$ then trivially $\int_S f d\mu \leq \int_S g d\mu$. Otherwise, by the additive property,

$$\int_S g d\mu = \int_S f d\mu + \int_S (g - f) d\mu \quad (3.11.7)$$

By the [positive property](#), $\int_S (g - f) d\mu \geq 0$ so $\int_S g d\mu \geq \int_S f d\mu$.

2. Except in the case that both integrals are ∞ or both are $-\infty$ we have

$$\int_S g d\mu - \int_S f d\mu = \int_S (g - f) d\mu \quad (3.11.8)$$

By assumption $g - f \geq 0$ almost everywhere on S , and hence by the [positive property](#), the integral on the right is 0 if and only if $g - f = 0$ almost everywhere on S .

So if $f \leq g$ almost everywhere on S then, except in the two cases mentioned, $\int_S f d\mu < \int_S g d\mu$ if and only if $\mu\{x \in S : f(x) < g(x)\} > 0$. The exclusion when both integrals are ∞ or $-\infty$ is important. A counterexample when this condition does not hold is given [below](#). The next result is the absolute value inequality.

Suppose that $f : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists. Then

$$\left| \int_S f d\mu \right| \leq \int_S |f| d\mu \quad (3.11.9)$$

If f is integrable, then equality holds if and only if $f \geq 0$ almost everywhere on S or $f \leq 0$ almost everywhere on S .

Proof

First note that $-|f| \leq f \leq |f|$ on S . The integrals of all three functions exist, so the increasing property and scaling properties give

$$-\int_S |f| d\mu \leq \int_S f d\mu \leq \int_S |f| d\mu \quad (3.11.10)$$

which is equivalent to the inequality above. If f is integrable, then by the [increasing property](#), equality holds if and only if $f = -|f|$ almost everywhere on S or $f = |f|$ almost everywhere on S . In the first case, $f \leq 0$ almost everywhere on S and in the second case, $f \geq 0$ almost everywhere on S .

Change of Variables

Suppose that (T, \mathcal{T}) is another measurable space and that $u : S \rightarrow T$ is measurable. As we saw in our first study of positive measures, ν defined by

$$\nu(B) = \mu[u^{-1}(B)], \quad B \in \mathcal{T} \quad (3.11.11)$$

is a positive measure on (T, \mathcal{T}) . The following result is known as the *change of variables* theorem.

If $f : T \rightarrow \mathbb{R}$ is measurable then, assuming that the integrals exist,

$$\int_T f d\nu = \int_S (f \circ u) d\mu \quad (3.11.12)$$

Proof

We will show that if either of the integrals exist then they both do, and are equal. The proof is a classical bootstrapping argument that parallels the definition of the integral.

1. Suppose first that f is a nonnegative simple function on T with the representation $f = \sum_{i \in I} b_i \mathbf{1}_{B_i}$ where I is a finite index set, $\{B_i : i \in I\}$ is a measurable partition of T , and $b_i \in [0, \infty)$ for $i \in I$. Recall that $f \circ u$ is a nonnegative simple function on S , with representation $f \circ u = \sum_{i \in I} b_i \mathbf{1}_{u^{-1}(B_i)}$. Hence

$$\int_T f \, d\nu = \sum_{i \in I} b_i \nu(B_i) = \sum_{i \in I} b_i \mu[u^{-1}(B_i)] = \int_S (f \circ u) \, d\mu \quad (3.11.13)$$

2. Next suppose that $f : T \rightarrow [0, \infty)$ is measurable, so that $f \circ u : S \rightarrow [0, \infty)$ is also measurable. There exists an increasing sequence (f_1, f_2, \dots) of nonnegative simple functions on T with $f_n \rightarrow f$ as $n \rightarrow \infty$. Then $(f_1 \circ u, f_2 \circ u, \dots)$ is an increasing sequence of simple functions on S with $f_n \circ u \rightarrow f \circ u$ as $n \rightarrow \infty$. By step (a), $\int_T f_n \, d\nu = \int_S (f_n \circ u) \, d\mu$ for each $n \in \mathbb{N}_+$. But by the monotone convergence theorem, $\int_T f_n \, d\nu \rightarrow \int_T f \, d\nu$ as $n \rightarrow \infty$ and $\int_S (f_n \circ u) \, d\mu \rightarrow \int_S (f \circ u) \, d\mu$ so we conclude that $\int_T f \, d\nu = \int_S (f \circ u) \, d\mu$.
3. Finally, suppose that $f : T \rightarrow \mathbb{R}$ is measurable, so that $f \circ u : S \rightarrow \mathbb{R}$ is also measurable. Note that $(f \circ u)^+ = f^+ \circ u$ and $(f \circ u)^- = f^- \circ u$. By part (b),

$$\int_T f^+ \, d\nu = \int_S (f^+ \circ u) \, d\mu = \int_S (f \circ u)^+ \, d\mu \quad (3.11.14)$$

$$\int_T f^- \, d\nu = \int_S (f^- \circ u) \, d\mu = \int_S (f \circ u)^- \, d\mu \quad (3.11.15)$$

Assuming that at least one of the integrals in the displayed equations is finite, we have

$$\int_T f \, d\nu = \int_T f^+ \, d\nu - \int_T f^- \, d\nu = \int_S (f \circ u)^+ \, d\mu - \int_S (f \circ u)^- \, d\mu = \int_S (f \circ u) \, d\mu \quad (3.11.16)$$

The change of variables theorem will look more familiar if we give the variables explicitly. Thus, suppose that we want to evaluate

$$\int_S f[u(x)] \, d\mu(x) \quad (3.11.17)$$

where again, $u : S \rightarrow T$ and $f : T \rightarrow \mathbb{R}$. One way is to use the substitution $u = u(x)$, find the new measure ν , and then evaluate

$$\int_T g(u) \, d\nu(u) \quad (3.11.18)$$

Convergence Properties

We start with a simple but important corollary of the monotone convergence theorem that extends the additivity property to a countably infinite sum of nonnegative functions.

Suppose that $f_n : S \rightarrow [0, \infty)$ is measurable for $n \in \mathbb{N}_+$. Then

$$\int_S \sum_{n=1}^{\infty} f_n \, d\mu = \sum_{n=1}^{\infty} \int_S f_n \, d\mu \quad (3.11.19)$$

Proof

Let $g_n = \sum_{i=1}^n f_i$ for $n \in \mathbb{N}_+$. Then $g_n : S \rightarrow [0, \infty)$ is measurable and g_n is increasing in n . Moreover, by definition, $g_n \rightarrow \sum_{i=1}^{\infty} f_i$ as $n \rightarrow \infty$. Hence by the MCT, $\int_S g_n \, d\mu \rightarrow \int_S \sum_{i=1}^{\infty} f_i \, d\mu$ as $n \rightarrow \infty$. But we know the additivity property holds for finite sums, so $\int_S g_n \, d\mu = \sum_{i=1}^n \int_S f_i \, d\mu$ and again, by definition, this sum converges to $\sum_{i=1}^{\infty} \int_S f_i \, d\mu$ as $n \rightarrow \infty$.

A [theorem below](#) gives a related result that relaxes the assumption that f be nonnegative, but imposes a stricter integrability requirement. Our next result is the additivity of the integral over a countably infinite collection of disjoint domains.

Suppose that $f : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists, and that $\{A_n : n \in \mathbb{N}_+\}$ is a disjoint collection of sets in \mathcal{S} . Let $A = \bigcup_{n=1}^{\infty} A_n$. Then

$$\int_A f \, d\mu = \sum_{n=1}^{\infty} \int_{A_n} f \, d\mu \quad (3.11.20)$$

Proof

Suppose first that f is nonnegative. Note that $\mathbf{1}_A = \sum_{n=1}^{\infty} \mathbf{1}_{A_n}$ and hence $\mathbf{1}_A f = \sum_{n=1}^{\infty} \mathbf{1}_{A_n} f$. Thus from the [theorem above](#),

$$\int_A f d\mu = \int_S \mathbf{1}_A f d\mu = \int_S \sum_{n=1}^{\infty} \mathbf{1}_{A_n} f d\mu = \sum_{n=1}^{\infty} \int_S \mathbf{1}_{A_n} f d\mu = \sum_{n=1}^{\infty} \int_{A_n} f d\mu \quad (3.11.21)$$

Suppose now that $f : S \rightarrow \mathbb{R}$ is measurable and $\int_S f d\mu$ exists. Note that for $B \in \mathcal{S}$, $(\mathbf{1}_B f)^+ = \mathbf{1}_B f^+$ and $(\mathbf{1}_B f)^- = \mathbf{1}_B f^-$. Hence from the previous argument,

$$\int_A f^+ d\mu = \sum_{n=1}^{\infty} \int_{A_n} f^+ d\mu, \quad \int_A f^- d\mu = \sum_{n=1}^{\infty} \int_{A_n} f^- d\mu \quad (3.11.22)$$

Both of these are sums of nonnegative terms, and one of the sums, at least, is finite. Hence we can group the terms to get

$$\int_A f d\mu = \int_A f^+ d\mu - \int_A f^- d\mu = \sum_{n=1}^{\infty} \int_{A_n} (f^+ - f^-) d\mu = \sum_{n=1}^{\infty} \int_{A_n} f d\mu \quad (3.11.23)$$

Of course, the previous theorem applies if f is nonnegative or if f is integrable. Next we give a minor extension of the monotone convergence theorem that relaxes the assumption that the functions be nonnegative.

Monotone Convergence Theorem. Suppose that $f_n : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists for each $n \in \mathbb{N}_+$ and that f_n is increasing in n on S . If $\int_S f_1 d\mu > -\infty$ then

$$\int_S \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu \quad (3.11.24)$$

Proof

Let $f(x) = \lim_{n \rightarrow \infty} f_n(x)$ for $x \in S$ which exists in $\mathbb{R} \cup \{\infty\}$ since $f_n(x)$ is increasing in $n \in \mathbb{N}_+$. If $\int_S f_1 d\mu = \infty$, then by the increasing property, $\int_S f_n d\mu = \infty$ for all $n \in \mathbb{N}_+$ and $\int_S f d\mu = \infty$, so the conclusion of the MCT trivially holds. Thus suppose that f_1 is integrable. Let $g_n = f_n - f_1$ for $n \in \mathbb{N}$ and let $g = f - f_1$. Then g_n is nonnegative and increasing in n on S , and $g_n \rightarrow g$ as $n \rightarrow \infty$ on S . By the ordinary MCT, $\int_S g_n d\mu \rightarrow \int_S g d\mu$ as $n \rightarrow \infty$. But since $\int_S f_1 d\mu$ is finite, $\int_S g_n d\mu = \int_S f_n d\mu - \int_S f_1 d\mu$ and $\int_S g d\mu = \int_S f d\mu - \int_S f_1 d\mu$. Again since $\int_S f_1 d\mu$ is finite, it follows that $\int_S f_n d\mu \rightarrow \int_S f d\mu$ as $n \rightarrow \infty$.

Here is the complementary result for decreasing functions.

Suppose that $f_n : S \rightarrow \mathbb{R}$ is a measurable function whose integral exists for each $n \in \mathbb{N}_+$ and that f_n is decreasing in n on S . If $\int_S f_1 d\mu < \infty$ then

$$\int_S \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu \quad (3.11.25)$$

Proof

The functions $-f_n$ for $n \in \mathbb{N}_+$ satisfy the hypotheses of the [MCT for increasing functions](#) and hence $\int_S \lim_{n \rightarrow \infty} -f_n d\mu = \lim_{n \rightarrow \infty} \int_S -f_n d\mu$. By the scaling property, $\int_S \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu$.

The additional assumptions on the integral of f_1 in the last two extensions of the monotone convergence theorem are necessary. An example is given in [below](#).

Our next result is also a consequence of the monotone convergence theorem, and is called *Fatou's lemma* in honor of Pierre Fatou. Its usefulness stems from the fact that no assumptions are placed on the integrand functions, except that they be nonnegative and measurable.

Fatou's Lemma. Suppose that $f_n : S \rightarrow [0, \infty)$ is measurable for $n \in \mathbb{N}_+$. Then

$$\int_S \liminf_{n \rightarrow \infty} f_n d\mu \leq \liminf_{n \rightarrow \infty} \int_S f_n d\mu \quad (3.11.26)$$

Proof

Let $g_n = \inf \{f_k : k \in \{n, n+1, \dots\}\}$ for $n \in \mathbb{N}_+$. Then $g_n : S \rightarrow [0, \infty)$ is measurable for $n \in \mathbb{N}_+$, g_n is increasing in n , and by definition, $\lim_{n \rightarrow \infty} g_n = \liminf_{n \rightarrow \infty} f_n$. By the MCT,

$$\int_S \liminf_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S g_n d\mu \quad (3.11.27)$$

But $g_n \leq f_k$ on S for $n \in \mathbb{N}_+$ and $k \in \{n, n+1, \dots\}$ so by the increasing property, $\int_S g_n d\mu \leq \int_S f_k d\mu$ for $n \in \mathbb{N}_+$ and $k \in \{n, n+1, \dots\}$. Hence $\int_S g_n d\mu \leq \inf \{\int_S f_k d\mu : k \in \{n, n+1, \dots\}\}$ for $n \in \mathbb{N}_+$ and therefore

$$\lim_{n \rightarrow \infty} \int_S g_n d\mu \leq \liminf_{n \rightarrow \infty} \int_S f_n d\mu \quad (3.11.28)$$

Given the weakness of the hypotheses, it's hardly surprising that strict inequality can easily occur in Fatou's lemma. An example is given [below](#).

Our next convergence result is one of the most important and is known as the *dominated convergence theorem*. It's sometimes also known as *Lebesgue's dominated convergence theorem* in honor of Henri Lebesgue, who first developed all of this stuff in the context of \mathbb{R}^n . The dominated convergence theorem gives a basic condition under which we may interchange the limit and integration operators.

Dominated Convergence Theorem. Suppose that $f_n : S \rightarrow \mathbb{R}$ is measurable for $n \in \mathbb{N}_+$ and that $\lim_{n \rightarrow \infty} f_n$ exists on S . Suppose also that $|f_n| \leq g$ for $n \in \mathbb{N}$ where $g : S \rightarrow [0, \infty)$ is integrable. Then

$$\int_S \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu \quad (3.11.29)$$

Proof

First note that by the increasing property, $\int_S |f_n| d\mu \leq \int_S g d\mu < \infty$ and hence f_n is integrable for $n \in \mathbb{N}_+$. Let $f = \lim_{n \rightarrow \infty} f_n$. Then f is measurable, and by the increasing property again, $\int_S |f| d\mu \leq \int_S g d\mu < \infty$, so f is integrable.

Now for $n \in \mathbb{N}_+$, let $u_n = \inf \{f_k : k \in \{n, n+1, \dots\}\}$ and let $v_n = \sup \{f_k : k \in \{n, n+1, \dots\}\}$. Then $u_n \leq f_n \leq v_n$ for $n \in \mathbb{N}_+$, u_n is increasing in n , v_n is decreasing in n , and $u_n \rightarrow f$ and $v_n \rightarrow f$ as $n \rightarrow \infty$. Moreover, $\int_S u_1 d\mu \geq -\int_S g d\mu > -\infty$ so by the version of the MCT above, $\int_S u_n d\mu \rightarrow \int_S f d\mu$ as $n \rightarrow \infty$. Similarly, $\int_S v_1 d\mu < \int_S g d\mu < \infty$, so by the MCT in (11), $\int_S v_n d\mu \rightarrow \int_S f d\mu$ as $n \rightarrow \infty$. But by the increasing property, $\int_S u_n d\mu \leq \int_S f_n d\mu \leq \int_S v_n d\mu$ for $n \in \mathbb{N}_+$ so by the squeeze theorem for limits, $\int_S f_n d\mu \rightarrow \int_S f d\mu$ as $n \rightarrow \infty$.

As you might guess, the assumption that $|f_n|$ is uniformly bounded in n by an integrable function is critical. A counterexample when this assumption is missing is given [below](#) when this assumption is missing. The dominated convergence theorem remains true if $\lim_{n \rightarrow \infty} f_n$ exists almost everywhere on S . The following corollary of the dominated convergence theorem gives a condition for the interchange of infinite sum and integral.

Suppose that $f_i : S \rightarrow \mathbb{R}$ is measurable for $i \in \mathbb{N}_+$ and that $\sum_{i=1}^{\infty} |f_i|$ is integrable. then

$$\int_S \sum_{i=1}^{\infty} f_i d\mu = \sum_{i=1}^{\infty} \int_S f_i d\mu \quad (3.11.30)$$

Proof

The assumption that $g = \sum_{i=1}^{\infty} |f_i|$ is integrable implies that $g < \infty$ almost everywhere on S . In turn, this means that $\sum_{i=1}^{\infty} f_i$ is absolutely convergent almost everywhere on S . Let $f(x) = \sum_{i=1}^{\infty} f_i(x)$ if $g(x) < \infty$, and for completeness, let $f(x) = 0$ if $g(x) = \infty$. Since only the integral of f appears in the theorem, it doesn't matter how we define f on the null set where $g = \infty$. Now let $g_n = \sum_{i=1}^n |f_i|$. Then $g_n \rightarrow g$ as $n \rightarrow \infty$ almost everywhere on S and $|g_n| \leq g$ on S . Hence by the [dominated convergence theorem](#), $\int_S g_n d\mu \rightarrow \int_S g d\mu$ as $n \rightarrow \infty$. But we know the additivity property holds for finite sums, so $\int_S g_n d\mu = \sum_{i=1}^n \int_S |f_i| d\mu$, and in turn this converges to $\sum_{i=1}^{\infty} \int_S |f_i| d\mu$ as $n \rightarrow \infty$. Thus we have $\sum_{i=1}^{\infty} \int_S |f_i| d\mu = \int_S g d\mu$.

The following corollary of the dominated convergence theorem is known as the *bounded convergence theorem*.

Bounded Convergence Theorem. Suppose that $f_n : S \rightarrow \mathbb{R}$ is measurable for $n \in \mathbb{N}_+$ and there exists $A \in \mathcal{S}$ such that $\mu(A) < \infty$, $\lim_{n \rightarrow \infty} f_n$ exists on A , and $|f_n|$ is bounded in $n \in \mathbb{N}_+$ on A . Then

$$\int_A \lim_{n \rightarrow \infty} f_n d\mu = \lim_{n \rightarrow \infty} \int_A f_n d\mu \quad (3.11.31)$$

Proof

Suppose that $|f_n|$ is bounded in n on A by $c \in (0, \infty)$. The constant c is integrable on A since $\int_A c d\mu = c\mu(A) < \infty$, and $|f_n| \leq c$ on A for $n \in \mathbb{N}_+$. Thus the result follows from the [dominated convergence theorem](#).

Again, the bounded convergence remains true if $\lim_{n \rightarrow \infty} f_n$ exists almost everywhere on A . For a finite measure space (and in particular for a probability space), the condition that $\mu(A) < \infty$ automatically holds.

Product Spaces

Suppose now that (S, \mathcal{S}, μ) and (T, \mathcal{T}, ν) are σ -finite measure spaces. Please recall the basic facts about the product σ -algebra $\mathcal{S} \otimes \mathcal{T}$ of subsets of $S \times T$, and the product measure $\mu \otimes \nu$ on $\mathcal{S} \otimes \mathcal{T}$. The product measure space $(S \times T, \mathcal{S} \otimes \mathcal{T}, \mu \otimes \nu)$ is the standard one that we use for product spaces. If $f : S \times T \rightarrow \mathbb{R}$ is measurable, there are three integrals we might consider. First, of course, is the integral of f with respect to the product measure $\mu \otimes \nu$

$$\int_{S \times T} f(x, y) d(\mu \otimes \nu)(x, y) \quad (3.11.32)$$

sometimes called a *double integral* in this context. But also we have the nested or *iterated integrals* where we integrate with respect to one variable at a time:

$$\int_S \left(\int_T f(x, y) d\nu(y) \right) d\mu(x), \quad \int_T \left(\int_S f(x, y) d\mu(x) \right) d\nu(y) \quad (3.11.33)$$

How are these integrals related? Well, just as in calculus with ordinary Riemann integrals, under mild conditions the three integrals are the same. The resulting important theorem is known as *Fubini's Theorem* in honor of the Italian mathematician Guido Fubini.

Fubini's Theorem. Suppose that $f : S \times T \rightarrow \mathbb{R}$ is measurable. If the double integral on the left exists, then

$$\int_{S \times T} f(x, y) d(\mu \otimes \nu)(x, y) = \int_S \int_T f(x, y) d\nu(y) d\mu(x) = \int_T \int_S f(x, y) d\mu(x) d\nu(y) \quad (3.11.34)$$

Proof

We will show that

$$\int_{S \times T} f(x, y) d(\mu \otimes \nu)(x, y) = \int_S \int_T f(x, y) d\nu(y) d\mu(x) \quad (3.11.35)$$

The proof with the other iterated integral is symmetric. The proof proceeds in stages, paralleling the definition of the integral.

1. Suppose that $f = \mathbf{1}_{A \times B}$ where $A \in \mathcal{S}$ and $B \in \mathcal{T}$. The equation holds by definition of the product measure, since the double integral is $(\mu \otimes \nu)(A \times B)$ and the iterated integral is

$$\int_S \int_T \mathbf{1}_{A \times B}(x, y) d\nu(y) d\mu(x) = \int_S \int_T \mathbf{1}_A(x) \mathbf{1}_B(y) d\nu(y) d\mu(x) = \int_S \mathbf{1}_A(x) \nu(B) d\mu(x) = \mu(A) \nu(B) \quad (3.11.36)$$

2. Consider $f = \mathbf{1}_C$ where $C \in \mathcal{S} \otimes \mathcal{T}$. The double integral is $(\mu \otimes \nu)(C)$, and so as a function of $C \in \mathcal{S} \otimes \mathcal{T}$ defines the measure $\mu \otimes \nu$. On the other hand, the iterated integral is

$$\int_S \int_T \mathbf{1}_C(x, y) d\nu(y) d\mu(x) = \int_S \int_T \mathbf{1}_{C_x}(y) d\nu(y) d\mu(x) = \int_S \nu(C_x) d\mu(x) \quad (3.11.37)$$

where $C_x = \{y \in T : (x, y) \in C\}$ is the cross-section of C at $x \in S$. Recall that $x \mapsto \nu(C_x)$ is a nonnegative, measurable function of x , so $C \mapsto \int_S \nu(C_x) d\mu(x)$ makes sense. Moreover, as a function of $C \in \mathcal{S} \otimes \mathcal{T}$, this integral also forms a measure: If $\{C^i : i \in I\}$ is a countable, disjoint collection sets in $\mathcal{S} \otimes \mathcal{T}$, then $\{C_x^i : i \in I\}$ is a countable,

disjoint collection of sets in \mathcal{T} . Cross-sections preserve set operations, so if $C = \bigcup_{i \in I} C^i$ then $C_x = \bigcup_{i \in I} C_x^i$. By the additivity of the measure ν and the integral we have

$$\int_S \nu(C_x) d\mu(x) = \int_S \nu\left(\bigcup_{i \in I} C_x^i\right) d\mu(x) = \int_S \sum_{i \in I} \nu(C_x^i) d\mu(x) = \sum_{i \in I} \int_S \nu(C_x^i) d\mu(x) \quad (3.11.38)$$

To summarize, the double integral and the iterated integral define positive measures on $\mathcal{S} \otimes \mathcal{T}$. By (a), these measures agree on the measurable rectangles. By the uniqueness theorem, they must be the same measure. Thus the double integral and the iterated integral agree with integrand $f = \mathbf{1}_C$ for every $C \in \mathcal{S} \otimes \mathcal{T}$.

3. Suppose $f = \sum_{i \in I} c_i \mathbf{1}_{C_i}$ is a nonnegative simple function on $S \times T$. Thus, I is a finite index set, $c_i \in [0, \infty)$ for $i \in I$, and $\{C_i : i \in I\}$ is a disjoint collection of sets in $\mathcal{S} \otimes \mathcal{T}$. The double integral and the iterated integral satisfy the linearity properties, and hence by (b), agree with integrand f .
4. Suppose that $f : S \times T \rightarrow [0, \infty)$ is measurable. Then there exists a sequence of nonnegative simple functions g_n , $n \in \mathbb{N}_+$ such that g_n is increasing in $n \in \mathbb{N}_+$ on $S \times T$, and $g_n \rightarrow f$ as $n \rightarrow \infty$ on $S \times T$. By the monotone convergence theorem, $\int_{S \times T} g_n d(\mu \otimes \nu) \rightarrow \int_{S \times T} f d(\mu \otimes \nu)$. But for fixed $x \in S$, $y \mapsto g_n(x, y)$ is increasing in n on T and has limit $f(x, y)$ as $n \rightarrow \infty$. By another application of the monotone convergence theorem, $\int_T g_n(x, y) d\nu(y) \rightarrow \int_T f(x, y) d\nu(y)$ as $n \rightarrow \infty$. But $x \mapsto \int_T g_n(x, y) d\nu(y)$ is measurable and is increasing in $n \in \mathbb{N}_+$ on S , so by yet another application of the monotone convergence theorem, $\int_S \int_T g_n(x, y) d\nu(y) d\mu(x) \rightarrow \int_S \int_T f(x, y) d\nu(y) d\mu(x)$ as $n \rightarrow \infty$. But the double integral and the iterated integral agree with integrand g_n by (c) for each $n \in \mathbb{N}_+$, so it follows that the double integral and the iterated integral agree with integrand f .
5. Suppose that $f : S \times T \rightarrow \mathbb{R}$ is measurable. By (d), the double integral and the iterated integral agree with integrand functions f^+ and f^- . Assuming that at least one of these is finite, then by the additivity property, they agree with integrand function $f = f^+ - f^-$.

Of course, the double integral exists, and so Fubini's theorem applies, if either f is nonnegative or integrable with respect to $\mu \otimes \nu$. When f is nonnegative, the result is sometimes called *Tonelli's theorem* in honor of another Italian mathematician, Leonida Tonelli. On the other hand, the iterated integrals may exist, and may be different, when the double integral does not exist. A [counterexample](#) and a [second counterexample](#) are given below.

A special case of Fubini's theorem (and indeed part of the proof) is that we can compute the measure of a set in the product space by integrating the cross-sectional measures.

If $C \in \mathcal{S} \otimes \mathcal{T}$ then

$$(\mu \otimes \nu)(C) = \int_S \nu(C_x) d\mu(x) = \int_T \mu(C^y) d\nu(y) \quad (3.11.39)$$

where $C_x = \{y \in T : (x, y) \in C\}$ for $x \in S$, and $C^y = \{x \in S : (x, y) \in C\}$ for $y \in T$.

In particular, if $C, D \in \mathcal{S} \otimes \mathcal{T}$ have the property that $\nu(C_x) = \nu(D_x)$ for all $x \in S$, or $\mu(C^y) = \mu(D^y)$ for all $y \in T$ (that is, C and D have the same cross-sectional measures with respect to one of the variables), then $(\mu \otimes \nu)(C) = (\mu \otimes \nu)(D)$. In \mathbb{R}^2 with area, and in \mathbb{R}^3 with volume (Lebesgue measure in both cases), this is known as *Cavalieri's principle*, named for Bonaventura Cavalieri, yet a third Italian mathematician. Clearly, Italian mathematicians cornered the market on theorems of this sort.

A simple corollary of Fubini's theorem is that the double integral of a product function over a product set is the product of the integrals. This result has important applications to independent random variables.

Suppose that $g : S \rightarrow \mathbb{R}$ and $h : T \rightarrow \mathbb{R}$ are measurable, and are either nonnegative or integrable with respect to μ and ν , respectively. Then

$$\int_{S \times T} g(x)h(y) d(\mu \otimes \nu)(x, y) = \left(\int_S g(x) d\mu(x) \right) \left(\int_T h(y) d\nu(y) \right) \quad (3.11.40)$$

Recall that a *discrete measure space* consists of a countable set with the σ -algebra of all subsets and with counting measure. In such a space, integrals are simply sums and so Fubini's theorem allows us to rearrange the order of summation in a double sum.

Suppose that I and J are countable and that $a_{ij} \in \mathbb{R}$ for $i \in I$ and $j \in J$. If the sum of the positive terms or the sum of the negative terms is finite, then

$$\sum_{(i,j) \in I \times J} a_{ij} = \sum_{i \in I} \sum_{j \in J} a_{ij} = \sum_{j \in J} \sum_{i \in I} a_{ij} \quad (3.11.41)$$

Often $I = J = \mathbb{N}_+$, and in this case, a_{ij} can be viewed as an infinite array, with $i \in \mathbb{N}_+$ the row number and $j \in \mathbb{N}_+$ the column number:

a_{11}	a_{12}	a_{13}	\dots
a_{21}	a_{22}	a_{23}	\dots
a_{31}	a_{32}	a_{33}	\dots
\vdots	\vdots	\vdots	\vdots

The significant point is that \mathbb{N}_+ is totally ordered. While there is no implied order of summation in the double sum $\sum_{(i,j) \in \mathbb{N}_+^2} a_{ij}$, the iterated sum $\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{ij}$ is obtained by summing over the rows in order and then summing the results by column in order, while the iterated sum $\sum_{j=1}^{\infty} \sum_{i=1}^{\infty} a_{ij}$ is obtained by summing over the columns in order and then summing the results by row in order.

Of course, only one of the product spaces might be discrete. Theorems (9) and (15) which give conditions for the interchange of sum and integral can be viewed as applications of Fubini's theorem, where one of the measure spaces is (S, \mathcal{S}, μ) and the other is \mathbb{N}_+ with counting measure.

Examples and Applications

Probability Spaces

Suppose that $(\Omega, \mathcal{F}, \mathbb{P})$ is a probability space, so that Ω is the set of outcomes of a random experiment, \mathcal{F} is the σ -algebra of events, and \mathbb{P} is a probability measure on the sample space (Ω, \mathcal{F}) . Suppose also that (S, \mathcal{S}) is another measurable space, and that X is a random variable for the experiment, taking values in S . Of course, this simply means that X is a measurable function from Ω to S . Recall that the *probability distribution* of X is the probability measure P_X on (S, \mathcal{S}) defined by

$$P_X(A) = \mathbb{P}(X \in A), \quad A \in \mathcal{S} \quad (3.11.42)$$

Since $\{X \in A\}$ is just probability notation for the inverse image of A under X , P_X is simply a special case of constructing a new positive measure from a given positive measure via a change of variables. Suppose now that $r : S \rightarrow \mathbb{R}$ is measurable, so that $r(X)$ is a real-valued random variable. The integral of $r(X)$ (assuming that it exists) is known as the *expected value* of $r(X)$ and is of fundamental importance. We will study expected values in detail in the next chapter. Here, we simply note different ways to write the integral. By the change of variables formula (8) we have

$$\int_{\Omega} r[X(\omega)] d\mathbb{P}(\omega) = \int_S r(x) dP_X(x) \quad (3.11.43)$$

Now let F_Y denote the distribution function of $Y = r(X)$. By another change of variables, Y has a probability distribution P_Y on \mathbb{R} , which is also a *Lebesgue-Stieltjes* measure, named for Henri Lebesgue and Thomas Stieltjes. Recall that this probability measure is characterized by

$$P_Y(a, b] = \mathbb{P}(a < Y \leq b) = F_Y(b) - F_Y(a); \quad a, b \in \mathbb{R}, \quad a < b \quad (3.11.44)$$

With another application of our change of variables theorem, we can add to our chain of integrals:

$$\int_{\Omega} r[X(\omega)] d\mathbb{P}(\omega) = \int_S r(x) dP_X(x) = \int_{\mathbb{R}} y dP_Y(y) = \int_{\mathbb{R}} y dF_Y(y) \quad (3.11.45)$$

Of course, the last two integrals are simply different notations for exactly the same thing. In the section on absolute continuity and density functions, we will see other ways to write the integral.

Counterexamples

In the first three exercises below, $(\mathbb{R}, \mathcal{R}, \lambda)$ is the standard one-dimensional Euclidean space, so \mathcal{R} is σ -algebra of Lebesgue measurable sets and λ is Lebesgue measure.

Let $f = \mathbf{1}_{[1, \infty)}$ and $g = \mathbf{1}_{[0, \infty)}$. Show that

1. $f \leq g$ on \mathbb{R}
2. $\lambda\{x \in \mathbb{R} : f(x) < g(x)\} = 1$
3. $\int_{\mathbb{R}} f d\lambda = \int_{\mathbb{R}} g d\lambda = \infty$

This example shows that the [strict increasing property](#) can fail when the integrals are infinite.

Let $f_n = \mathbf{1}_{[n, \infty)}$ for $n \in \mathbb{N}_+$. Show that

1. f_n is decreasing in $n \in \mathbb{N}_+$ on \mathbb{R} .
2. $f_n \rightarrow 0$ as $n \rightarrow \infty$ on \mathbb{R} .
3. $\int_{\mathbb{R}} f_n d\lambda = \infty$ for each $n \in \mathbb{N}_+$.

This example shows that the [monotone convergence theorem](#) can fail if the first integral is infinite. It also illustrates strict inequality in [Fatou's lemma](#).

Let $f_n = \mathbf{1}_{[n, n+1]}$ for $n \in \mathbb{N}_+$. Show that

1. $\lim_{n \rightarrow \infty} f_n = 0$ on \mathbb{R} so $\int_{\mathbb{R}} \lim_{n \rightarrow \infty} f_n d\mu = 0$
2. $\int_{\mathbb{R}} f_n d\lambda = 1$ for $n \in \mathbb{N}_+$ so $\lim_{n \rightarrow \infty} \int_{\mathbb{R}} f_n d\lambda = 1$
3. $\sup\{f_n : n \in \mathbb{N}_+\} = \mathbf{1}_{[1, \infty)}$ on \mathbb{R}

This example shows that the [dominated convergence theorem](#) can fail if $|f_n|$ is not bounded by an integrable function. It also shows that strict inequality can hold in [Fatou's lemma](#).

Consider the product space $[0, 1]^2$ with the usual Lebesgue measurable subsets and Lebesgue measure. Let $f : [0, 1]^2 \rightarrow \mathbb{R}$ be defined by

$$f(x, y) = \frac{x^2 - y^2}{(x^2 + y^2)^2} \quad (3.11.46)$$

Show that

1. $\int_{[0, 1]^2} f(x, y) d(x, y)$ does not exist.
2. $\int_0^1 \int_0^1 f(x, y) dx dy = -\frac{\pi}{4}$
3. $\int_0^1 \int_0^1 f(x, y) dy dx = \frac{\pi}{4}$

This example shows that [Fubini's theorem](#) can fail if the double integral does not exist.

For $i, j \in \mathbb{N}_+$ define the sequence a_{ij} as follows: $a_{ii} = 1$ and $a_{i+1, i} = -1$ for $i \in \mathbb{N}_+$, $a_{ij} = 0$ otherwise.

1. Give a_{ij} in array form with $i \in \mathbb{N}_+$ as the row number and $j \in \mathbb{N}_+$ as the column number
2. Show that $\sum_{(i, j) \in \mathbb{N}_+^2} a_{ij}$ does not exist
3. Show that $\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{ij} = 1$
4. Show that $\sum_{j=1}^{\infty} \sum_{i=1}^{\infty} a_{ij} = 0$

This example shows that the iterated sums can exist and be different when the double sum does not exist, a counterexample to the [corollary to Fubini's theorem](#) for sums when the hypotheses are not satisfied.

Computational Exercises

Compute $\int_D f(x, y) d(x, y)$ in each case below for the given $D \subseteq \mathbb{R}^2$ and $f : D \rightarrow \mathbb{R}$.

1. $f(x, y) = e^{-2x} e^{-3y}$, $D = [0, \infty) \times [0, \infty)$

$$2. f(x, y) = e^{-2x} e^{-3y}, D = \{(x, y) \in \mathbb{R}^2 : 0 \leq x \leq y < \infty\}$$

Integrals of the type in the last exercise are useful in the study of exponential distributions.

This page titled [3.11: Properties of the Integral](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

3.12: General Measures

Basic Theory

Our starting point in this section is a measurable space (S, \mathcal{S}) . That is, S is a set and \mathcal{S} is a σ -algebra of subsets of S . So far, we have only considered positive measures on such spaces. Positive measures have applications, as we know, to length, area, volume, mass, probability, counting, and similar concepts of the nonnegative “size” of a set. Moreover, we have defined the integral of a measurable function $f : S \rightarrow \mathbb{R}$ with respect to a positive measure, and we have studied properties of the integral.

Definition

But now we will consider measures that can take negative values as well as positive values. These measures have applications to electric charge, monetary value, and other similar concepts of the “content” of a set that might be positive or negative. Also, this generalization will help in our study of density functions in the next section. The definition is exactly the same as for a positive measure, except that values in $\mathbb{R}^* = \mathbb{R} \cup \{-\infty, \infty\}$ are allowed.

A *measure* on (S, \mathcal{S}) is a function $\mu : \mathcal{S} \rightarrow \mathbb{R}^*$ that satisfies the following properties:

1. $\mu(\emptyset) = 0$
2. If $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} then $\mu(\bigcup_{i \in I} A_i) = \sum_{i \in I} \mu(A_i)$

As before, (b) is known as *countable additivity* and is the critical assumption: the measure of a set that consists of a countable number of disjoint pieces is the sum of the measures of the pieces. Implicit in the statement of this assumption is that the sum in (b) exists for every countable disjoint collection $\{A_i : i \in I\}$. That is, either the sum of the positive terms is finite or the sum of the negative terms is finite. In turn, this means that the order of the terms in the sum does not matter (a good thing, since there is no implied order). The term *signed measure* is used by many, but we will just use the simple term *measure*, and add appropriate adjectives for the special cases. Note that if $\mu(A) \geq 0$ for all $A \in \mathcal{S}$, then μ is a *positive measure*, the kind we have already studied (and so the new definition really is a generalization). In this case, the sum in (b) always exists in $[0, \infty]$. If $\mu(A) \in \mathbb{R}$ for all $A \in \mathcal{S}$ then μ is a *finite measure*. Note that in this case, the sum in (b) is absolutely convergent for every countable disjoint collection $\{A_i : i \in I\}$. If μ is a positive measure and $\mu(S) = 1$ then μ is a *probability measure*, our favorite kind. Finally, as with positive measures, μ is σ -finite if there exists a countable collection $\{A_i : i \in I\}$ of sets in \mathcal{S} such that $S = \bigcup_{i \in I} A_i$ and $\mu(A_i) \in \mathbb{R}$ for $i \in I$.

Basic Properties

We give a few simple properties of general measures; hopefully many of these will look familiar. Throughout, we assume that μ is a measure on (S, \mathcal{S}) . Our first result is that although μ can take the value ∞ or $-\infty$, it turns out that it cannot take both of these values.

Either $\mu(A) > -\infty$ for all $A \in \mathcal{S}$ or $\mu(A) < \infty$ for all $A \in \mathcal{S}$.

Proof

Suppose that there exist $A, B \in \mathcal{S}$ with $\mu(A) = \infty$ and $\mu(B) = -\infty$. Then $A = (A \cap B) \cup (A \setminus B)$ and the sets in the union are disjoint. By the additivity assumption, $\mu(A) = \mu(A \cap B) + \mu(A \setminus B)$. Similarly, $\mu(B) = \mu(A \cap B) + \mu(B \setminus A)$. The only way that both of these equations can make sense is for $\mu(A \setminus B) = \infty$, $\mu(B \setminus A) = -\infty$, and $\mu(A \cap B) \in \mathbb{R}$. But then $\mu(A \triangle B) = \mu(A \setminus B) + \mu(B \setminus A)$ is undefined, and so we have a contradiction.

We will say that two measures are *of the same type* if neither takes the value ∞ or if neither takes the value $-\infty$. *Being of the same type* is trivially an equivalence relation on the collection of measures on (S, \mathcal{S}) .

The difference rule holds, as long as the sets have finite measure:

Suppose that $A, B \in \mathcal{S}$. If $\mu(B) \in \mathbb{R}$ then $\mu(B \setminus A) = \mu(B) - \mu(A \cap B)$.

Proof

Note that $B = (A \cap B) \cup (B \setminus A)$ and the sets in the union are disjoint. Thus $\mu(B) = \mu(A \cap B) + \mu(B \setminus A)$. Since $\mu(B) \in \mathbb{R}$, we must have $\mu(A \cap B) \in \mathbb{R}$ and $\mu(B \setminus A) \in \mathbb{R}$ also, and then the difference rule holds by subtraction.

The following corollary is the difference rule for subsets, and will be needed below.

Suppose that $A, B \in \mathcal{S}$ and $A \subseteq B$. If $\mu(B) \in \mathbb{R}$ then $\mu(A) \in \mathbb{R}$ and $\mu(B \setminus A) = \mu(B) - \mu(A)$.

Proof

Note that $B = A \cup (B \setminus A)$ and the sets in the union are disjoint. Thus $\mu(B) = \mu(A) + \mu(B \setminus A)$. Since $\mu(B) \in \mathbb{R}$, we must have $\mu(A) \in \mathbb{R}$ and $\mu(B \setminus A) \in \mathbb{R}$ also, and then the difference rule holds by subtraction.

As a consequence, suppose that $A, B \in \mathcal{S}$ and $A \subseteq B$. If $\mu(A) = \infty$, then by the [infinity rule](#) we cannot have $\mu(B) = -\infty$ and by the [difference rule](#) we cannot have $\mu(B) \in \mathbb{R}$, so we must have $\mu(B) = \infty$. Similarly, if $\mu(A) = -\infty$ then $\mu(B) = -\infty$. The *inclusion-exclusion* rules hold for general measures, as long as the sets have finite measure.

Suppose that $A_i \in \mathcal{S}$ for each $i \in I$ where $\#(I) = n$, and that $\mu(A_i) \in \mathbb{R}$ for $i \in I$. Then

$$\mu\left(\bigcup_{i \in I} A_i\right) = \sum_{k=1}^n (-1)^{k-1} \sum_{J \subseteq I, \#(J)=k} \mu\left(\bigcap_{j \in J} A_j\right) \quad (3.12.1)$$

Proof

For $n = 2$, note that $A_1 \cup A_2 = A_1 \cup (A_2 \setminus A_1)$ and the sets in the last union are disjoint. By the additivity axiom and the difference rule (3),

$$\mu(A_1 \cup A_2) = \mu(A_1) + \mu(A_2 \setminus A_1) = \mu(A_1) + \mu(A_2) - \mu(A_1 \cap A_2) \quad (3.12.2)$$

The general result then follows by induction, just like the proof for probability measures.

The *continuity properties* hold for general measures. Part (a) is the continuity property for *increasing sets*, and part (b) is the continuity property for *decreasing sets*.

Suppose that $A_n \in \mathcal{S}$ for $n \in \mathbb{N}_+$.

1. If $A_n \subseteq A_{n+1}$ for $n \in \mathbb{N}_+$ then $\lim_{n \rightarrow \infty} \mu(A_n) = \mu(\bigcup_{i=1}^{\infty} A_i)$.
2. If $A_{n+1} \subseteq A_n$ for $n \in \mathbb{N}_+$ and $\mu(A_1) \in \mathbb{R}$, then $\lim_{n \rightarrow \infty} \mu(A_n) = \mu(\bigcap_{i=1}^{\infty} A_i)$.

Proof

The proofs are almost the same as for positive measures, except for technicalities involving ∞ and $-\infty$.

1. Let $A = \bigcup_{i=1}^{\infty} A_i$. From the [infinity rule](#) and the [difference rule](#), if $\mu(A_m) = \infty$ (respectively $-\infty$) for some $m \in \mathbb{N}_+$, then $\mu(A_n) = \infty$ ($-\infty$) for $n \geq m$ and $\mu(A) = \infty$ ($-\infty$), so the result trivially holds. Thus, assume that $\mu(A_n) \in \mathbb{R}$ for all $n \in \mathbb{N}_+$. Let $B_1 = A_1$ and let $B_i = A_i \setminus A_{i-1}$ for $i \in \{2, 3, \dots\}$. Then $\{B_i : i \in \mathbb{N}_+\}$ is a disjoint collection of sets and also has union A . Moreover, from the [difference rule](#), $\mu(B_i) = \mu(A_{i+1}) - \mu(A_i)$ for $i \in \{2, 3, \dots\}$. Thus

$$\mu(A) = \sum_{i=1}^{\infty} \mu(B_i) = \lim_{n \rightarrow \infty} \sum_{i=1}^n \mu(B_i) = \lim_{n \rightarrow \infty} \left(\mu(A_1) + \sum_{i=2}^n [\mu(A_i) - \mu(A_{i-1})] \right) = \lim_{n \rightarrow \infty} \mu(A_n) \quad (3.12.3)$$

2. Let $C_n = A_1 \setminus A_n$ for $n \in \mathbb{N}_+$. Then $C_n \subseteq C_{n+1}$ for $n \in \mathbb{N}_+$ and $\bigcup_{i=1}^{\infty} C_i = A_1 \setminus \bigcap_{i=1}^{\infty} A_i$. Part (a) applies, so $\lim_{n \rightarrow \infty} \mu(C_n) = \mu(\bigcup_{i=1}^{\infty} C_i)$. But by the [difference rule](#), $\mu(C_n) = \mu(A_1) - \mu(A_n)$ for $n \in \mathbb{N}_+$ and $\mu(\bigcup_{i=1}^{\infty} C_i) = \mu(A_1) - \mu(\bigcap_{i=1}^{\infty} A_i)$. All of these are real numbers, so subtracting $\mu(A_1)$ gives the result.

Recall that a positive measure is an increasing function, relative to the subset partial order on \mathcal{S} and the ordinary order on $[0, \infty]$, and this property follows from the [difference rule](#). But for general measures, the increasing property fails, and so do other properties that flow from it, including the subadditive property (Boole's inequality in probability) and the Bonferroni inequalities.

Constructions

It's easy to construct general measures as differences of positive measures.

Suppose that μ and ν are positive measures on (S, \mathcal{S}) and that at least one of them is finite. Then $\delta = \mu - \nu$ is a measure.

Proof

Suppose that ν is a finite measure; the proof when μ is finite is similar. First, $\delta(\emptyset) = \mu(\emptyset) - \nu(\emptyset) = 0$. Suppose that $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} and let $A = \bigcup_{i \in I} A_i$. Then

$$\delta(A) = \mu(A) - \nu(A) = \sum_{i \in I} \mu(A_i) - \sum_{i \in I} \nu(A_i) \quad (3.12.4)$$

Since $\nu(A_i) < \infty$ for $i \in I$, we can combine terms to get

$$\delta(A) = \sum_{i \in I} [\mu(A_i) - \nu(A_i)] = \sum_{i \in I} \delta(A_i) \quad (3.12.5)$$

The collection of measures on our space is closed under scalar multiplication.

If μ is a measure on (S, \mathcal{S}) and $c \in \mathbb{R}$, then $c\mu$ is a measure on (S, \mathcal{S})

Proof

First, $(c\mu)(\emptyset) = c\mu(\emptyset) = c0 = 0$. Next suppose that $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} . Then

$$(c\mu)\left(\bigcup_{i \in I} A_i\right) = c\mu\left(\bigcup_{i \in I} A_i\right) = c \sum_{i \in I} \mu(A_i) = \sum_{i \in I} c\mu(A_i) = \sum_{i \in I} (c\mu)(A_i) \quad (3.12.6)$$

The last step is the important one, and holds since the sum exists.

If μ is a finite measure, then so is $c\mu$ for $c \in \mathbb{R}$. If μ is not finite then μ and $c\mu$ are of the same type if $c > 0$ and are of opposite types if $c < 0$. We can add two measures to get another measure, as long as they are of the same type. In particular, the collection of *finite* measures is closed under addition as well as scalar multiplication, and hence forms a vector space.

If μ and ν are measures on (S, \mathcal{S}) of the same type then $\mu + \nu$ is a measure on (S, \mathcal{S}) .

Proof

First, $(\mu + \nu)(\emptyset) = \mu(\emptyset) + \nu(\emptyset) = 0 + 0 = 0$. Next suppose that $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} . Then

$$\begin{aligned} (\mu + \nu)\left(\bigcup_{i \in I} A_i\right) &= \mu\left(\bigcup_{i \in I} A_i\right) + \nu\left(\bigcup_{i \in I} A_i\right) \\ &= \sum_{i \in I} \mu(A_i) + \sum_{i \in I} \nu(A_i) = \sum_{i \in I} [\mu(A_i) + \nu(A_i)] = \sum_{i \in I} (\mu + \nu)(A_i) \end{aligned}$$

The sums can be combined because the measures are of the same type. That is, either the sum of all of the positive terms is finite or the sum of all the negative terms is finite. In short, we don't have to worry about the dreaded indeterminate form $\infty - \infty$.

Finally, it is easy to explicitly construct measures on a σ -algebra generated by a countable partition. Such σ -algebras are important for counterexamples and to gain insight, and also because many σ -algebras that occur in applications can be constructed from them.

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ is a countable partition of S into nonempty sets, and that $\mathcal{S} = \sigma(\mathcal{A})$. For $i \in I$, define $\mu(A_i) \in \mathbb{R}^*$ arbitrarily, subject only to the condition that the sum of the positive terms is finite, or the sum of the negative terms is finite. For $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$, define

$$\mu(A) = \sum_{j \in J} \mu(A_j) \quad (3.12.7)$$

Then μ is a measure on (S, \mathcal{S}) .

Proof

Recall that every $A \in \mathcal{S}$ has a unique representation of the form $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$.

1. $J = \emptyset$ in the representation gives $A = \emptyset$. The sum over an empty index set is 0, so $\mu(\emptyset) = 0$.

2. Suppose that $\{B_k : k \in K\}$ is a countable, disjoint collection of events in \mathcal{S} . Then for each $k \in K$ there exists $J_k \subseteq I$ and $\{A_j^k : j \in J_k\} \subseteq \mathcal{A}$ such that $B_k = \bigcup_{j \in J_k} A_j^k$. Hence

$$\mu\left(\bigcup_{k \in K} B_k\right) = \mu\left(\bigcup_{k \in K} \bigcup_{j \in J_k} A_j^k\right) = \sum_{k \in K} \sum_{j \in J_k} \mu(A_j^k) = \sum_{k \in K} \mu(B_k) \quad (3.12.8)$$

The fact that either the sum of all positive terms is finite or the sum of all the negative terms is finite means that we do not have to worry about the order of summation.

Positive, Negative, and Null Sets

To understand the structure of general measures, we need some basic definitions and properties. As before, we assume that μ is a measure on (S, \mathcal{S}) .

Definitions

1. $A \in \mathcal{S}$ is a *positive set* for μ if $\mu(B) \geq 0$ for every $B \in \mathcal{S}$ with $B \subseteq A$.
2. $A \in \mathcal{S}$ is a *negative set* for μ if $\mu(B) \leq 0$ for every $B \in \mathcal{S}$ with $B \subseteq A$.
3. $A \in \mathcal{S}$ is a *null set* for μ if $\mu(B) = 0$ for every $B \in \mathcal{S}$ with $B \subseteq A$.

Note that *positive* and *negative* are used in the weak sense (just as we use the terms *increasing* and *decreasing* in this text). Of course, if μ is a positive measure, then every $A \in \mathcal{S}$ is positive for μ , and $A \in \mathcal{S}$ is negative for μ if and only if A is null for μ if and only if $\mu(A) = 0$. For a general measure, $A \in \mathcal{S}$ is both positive and negative for μ if and only if A is null for μ . In particular, \emptyset is null for μ . A set $A \in \mathcal{S}$ is a *support set* for μ if and only if A^c is a null set for μ . A support set is a set where the measure “lives” in a sense. Positive, negative, and null sets for μ have a basic inheritance property that is essentially equivalent to the definition.

Suppose $A \in \mathcal{S}$.

1. If A is positive for μ then B is positive for μ for every $B \in \mathcal{S}$ with $B \subseteq A$.
2. If A is negative for μ then B is negative for μ for every $B \in \mathcal{S}$ with $B \subseteq A$.
3. If A is null for μ then B is null for μ for every $B \in \mathcal{S}$ with $B \subseteq A$.

The collections of positive sets, negative sets, and null sets for μ are closed under countable unions.

Suppose that $\{A_i : i \in I\}$ is a countable collection of sets in \mathcal{S} .

1. If A_i is positive for μ for $i \in I$ then $\bigcup_{i \in I} A_i$ is positive for μ .
2. If A_i is negative for μ for $i \in I$ then $\bigcup_{i \in I} A_i$ is negative for μ .
3. If A_i is null for μ for $i \in I$ then $\bigcup_{i \in I} A_i$ is null for μ .

Proof

We will prove (a); the proofs for (b) and (c) are analogous. Without loss of generality, we can suppose that $I = \mathbb{N}_+$. Let $A = \bigcup_{n=1}^{\infty} A_n$. Now let $B_1 = A_1$ and $B_n = A_n \setminus \left(\bigcup_{i=1}^{n-1} A_i\right)$ for $n \in \{2, 3, \dots\}$. Then $\{B_n : n \in \mathbb{N}_+\}$ is a countable, disjoint collection in \mathcal{S} , and $\bigcup_{n=1}^{\infty} B_n = A$. If $C \subseteq A$ then $C = \bigcup_{n=1}^{\infty} (C \cap B_n)$ and the sets in this union are disjoint. Hence by additivity, $\mu(C) = \sum_{n=1}^{\infty} \mu(C \cap B_n)$. But $C \cap B_n \subseteq B_n \subseteq A_n$ so $\mu(C \cap B_n) \geq 0$. Hence $\mu(C) \geq 0$.

It's easy to see what happens to the positive, negative, and null sets when a measure is multiplied by a non-zero constant.

Suppose that μ is a measure on (S, \mathcal{S}) , $c \in \mathbb{R}$, and $A \in \mathcal{S}$.

1. If $c > 0$ then A is positive (negative) for μ if and only if A is positive (negative) for $c\mu$.
2. If $c < 0$ then A is positive (negative) for μ if and only if A is negative (positive) for $c\mu$.
3. If $c \neq 0$ then A is null for μ if and only if A is null for $c\mu$.

Positive, negative, and null sets are also preserved under countable sums, assuming that the measures make sense.

Suppose that μ_i is a measure on (S, \mathcal{S}) for each i in a countable index set I , and that $\mu = \sum_{i \in I} \mu_i$ is a well-defined measure on (S, \mathcal{S}) . Let $A \in \mathcal{S}$.

1. If A is positive for μ_i for every $i \in I$ then A is positive for μ .
2. If A is negative for μ_i for every $i \in I$ then A is negative for μ .
3. If A is null for μ_i for every $i \in I$ then A is null for μ .

In particular, note that $\mu = \sum_{i \in I} \mu_i$ is a well-defined measure if μ_i is a positive measure for each $i \in I$, or if I is finite and μ_i is a finite measure for each $i \in I$. It's easy to understand the positive, negative, and null sets for a σ -algebra generated by a [countable partition](#).

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ is a countable partition of S into nonempty sets, and that $\mathcal{S} = \sigma(\mathcal{A})$. Suppose that μ is a measure on (S, \mathcal{S}) . Define

$$I_+ = \{i \in I : \mu(A_i) > 0\}, \quad I_- = \{i \in I : \mu(A_i) < 0\}, \quad I_0 = \{i \in I : \mu(A_i) = 0\} \quad (3.12.9)$$

Let $A \in \mathcal{S}$, so that $A = \bigcup_{j \in J} A_j$ for some $J \subseteq I$ (and this representation is unique). Then

1. A is positive for μ if and only if $J \subseteq I_+ \cup I_0$.
2. A is negative for μ if and only if $J \subseteq I_- \cup I_0$.
3. A is null for μ if and only if $J \subseteq I_0$.

The Hahn Decomposition

The fundamental results in this section and the next are two decomposition theorems that show precisely the relationship between general measures and positive measures. First we show that if a set has finite, positive measure, then it has a positive subset with at least that measure.

If $A \in \mathcal{S}$ and $0 \leq \mu(A) < \infty$ then there exists $P \in \mathcal{S}$ with $P \subseteq A$ such that P is positive for μ and $\mu(P) \geq \mu(A)$.

Proof

The proof is recursive, and works by successively removing sets of negative measure from A . For the initialization step, let $A_0 = A$. Then trivially, $A_0 \subseteq A$ and $\mu(A_0) \geq \mu(A)$. For the recursive step, suppose that $A_n \in \mathcal{S}$ has been defined with $A_n \subseteq A$ and $\mu(A_n) \geq \mu(A)$. If A_n is positive for μ , let $P = A_n$. Otherwise let $a_n = \inf\{\mu(B) : B \in \mathcal{S}, B \subseteq A_n, \mu(B) < 0\}$. Note that since A_n is not positive for μ , the set in the infimum is nonempty and hence $a_n < 0$ (and possibly $-\infty$). Let $b_n = a_n/2$ if $-\infty < a_n < 0$ and let $b_n = -1$ if $a_n = -\infty$. Since $b_n > a_n$, by definition of the infimum, there exists $B_n \subseteq A$ with $\mu(B_n) \leq b_n$. Let $A_{n+1} = A_n \setminus B_n$. Then $A_{n+1} \subseteq A_n \subseteq A$ and

$$\mu(A_{n+1}) = \mu(A_n) - \mu(B_n) \geq \mu(A_n) - b_n \geq \mu(A_n) \geq \mu(A) \quad (3.12.10)$$

Now, if the recursive process terminates after a finite number of steps, P is well defined and is positive for μ . Otherwise, we have a disjoint sequence of sets (B_1, B_2, \dots) . Let $P = A \setminus (\bigcup_{i=1}^{\infty} B_i)$. Then $P \subseteq A$, and by countable additivity and the [difference rule](#),

$$\mu(P) = \mu(A) - \sum_{n=1}^{\infty} \mu(B_n) \geq \mu(A) - \sum_{n=1}^{\infty} b_n \geq \mu(A) \quad (3.12.11)$$

Suppose that $B \subseteq P$ and $\mu(B) < 0$. Then $B \subseteq A_n$ and by definition, $a_n \leq \mu(B)$ for every $n \in \mathbb{N}_+$. It follows that $b_n \leq \frac{1}{2}\mu(B)$ or $b_n = -1$ for every $n \in \mathbb{N}_+$. Hence $\sum_{n=1}^{\infty} b_n = -\infty$ and therefore $\mu(P) = \infty$, a contradiction since $\mu(A) < \infty$. Hence we must have $\mu(B) \geq 0$ and thus P is positive for μ .

The assumption that $\mu(A) < \infty$ is critical; a [counterexample](#) is given below. Our first decomposition result is the *Hahn decomposition theorem*, named for the Austrian mathematician Hans Hahn. It states that S can be partitioned into a positive set and a negative set, and this decomposition is essentially unique.

Hahn Decomposition Theorem. There exists $P \in \mathcal{S}$ such that P is positive for μ and P^c is negative for μ . The pair (P, P^c) is a *Hahn decomposition* of S . If (Q, Q^c) is another Hahn decomposition, then $P \triangle Q$ is null for μ .

Proof

Suppose first that μ does not take the value ∞ . As with the previous result, the proof is recursive. For the initialization step, let $P_0 = \emptyset$. Then trivially, P_0 is positive for μ . For the recursive step, suppose that $P_n \in \mathcal{S}$ is positive for μ . If P_n^c is negative for μ , let $P = P_n$. Otherwise let $a_n = \sup\{\mu(A) : A \in \mathcal{S}, A \subseteq P_n^c\}$. Since P_n^c is not negative for μ , it follows that $a_n > 0$ (and possibly ∞). Let $b_n = a_n/2$ if $0 < a_n < \infty$ and $b_n = 1$ if $a_n = \infty$. Then $b_n < a_n$ so there exists $B_n \in \mathcal{S}$ with $B_n \subseteq P_n^c$ and $\mu(B_n) \geq b_n > 0$. By the [previous lemma](#), there exists $A_n \in \mathcal{S}$ with $A_n \subseteq B_n$, A_n positive for μ , and $\mu(A_n) \geq \mu(B_n)$. Let $P_{n+1} = P_n \cup A_n$. Then $P_{n+1} \in \mathcal{S}$ is positive for μ .

If the recursive process ends after a finite number of steps, then P is well-defined and (P, P^c) is a Hahn decomposition. Otherwise we generate an infinite sequence (A_1, A_2, \dots) of disjoint sets in \mathcal{S} , each positive for μ . Let $P = \bigcup_{n=1}^{\infty} A_n$. Then $P \in \mathcal{S}$ is positive for μ by the [closure result](#) above. Let $A \subseteq P^c$. If $\mu(A) > 0$ then $\mu(A) \leq a_n$ for every $n \in \mathbb{N}_+$. Hence $b_n \geq \frac{1}{2}\mu(A)$ or $b_n = 1$ for every $n \in \mathbb{N}_+$. But then

$$\mu(P) = \sum_{n=1}^{\infty} \mu(A_n) \geq \sum_{n=1}^{\infty} \mu(B_n) \geq \sum_{n=1}^{\infty} b_n = \infty \quad (3.12.12)$$

a contradiction. Hence $\mu(A) \leq 0$ so P^c is negative for μ and thus (P, P^c) is a Hahn decomposition.

Suppose that (Q, Q^c) is another Hahn decomposition of S . Then $P \cap Q^c$ and $Q \cap P^c$ are both positive and negative for μ and hence are null for μ . Hence $P \triangle Q = (P \cap Q^c) \cup (Q \cap P^c)$ is null for μ .

Finally, suppose that μ takes the value ∞ . Then μ does not take the value $-\infty$ by the [infinity rule](#) and hence $-\mu$ does not take the value ∞ . By our proof so far, there exists a Hahn decomposition (P, P^c) for $-\mu$ that is essentially unique. But then (P^c, P) is a Hahn decomposition for μ .

It's easy to see the Hahn decomposition for a measure on a σ -algebra generated by a [countable partition](#).

Suppose that $\mathcal{A} = \{A_i : i \in I\}$ is a countable partition of S into nonempty sets, and that $\mathcal{S} = \sigma(\mathcal{A})$. Suppose that μ is a measure on (S, \mathcal{S}) . Let $I_+ = \{i \in I : \mu(A_i) > 0\}$ and $I_0 = \{i \in I : \mu(A_i) = 0\}$. Then (P, P^c) is a Hahn decomposition of μ if and only if the positive set P has the form $P = \bigcup_{j \in J} A_j$ where $J = I_+ \cup K$ and $K \subseteq I_0$.

The Jordan Decomposition

The Hahn decomposition leads to another decomposition theorem called the *Jordan decomposition theorem*, named for the French mathematician Camille Jordan. This one shows that every measure is the [difference of positive measures](#). Once again we assume that μ is a measure on (S, \mathcal{S}) .

Jordan Decomposition Theorem. The measure μ can be written uniquely in the form $\mu = \mu_+ - \mu_-$ where μ_+ and μ_- are positive measures, at least one finite, and with the property that if (P, P^c) is any Hahn decomposition of S , then P^c is a null set of μ_+ and P is a null set of μ_- . The pair (μ_+, μ_-) is the *Jordan decomposition* of μ .

Proof

Let (P, P^c) be a Hahn decomposition of S relative to μ . Define $\mu_+(A) = \mu(A \cap P)$ and $\mu_-(A) = -\mu(A \cap P^c)$ for $A \in \mathcal{S}$. Then μ_+ and μ_- are positive measures and $\mu = \mu_+ - \mu_-$. Moreover, since μ cannot take both ∞ and $-\infty$ as values by the [infinity rule](#), one of these two positive measures is finite.

Suppose that (Q, Q^c) is an arbitrary Hahn decomposition. If $A \subseteq Q^c$, then $\mu_+(A) = \mu(P \cap A) = 0$ since $P \cap Q^c$ is a null set of μ by the [Hahn decomposition theorem](#). Similarly if $A \subseteq Q$ then $\mu_-(A) = \mu(P^c \cap A) = 0$ since $P^c \cap Q$ is a null set of μ .

Suppose that $\mu = \nu_+ - \nu_-$ is another decomposition with the same properties. If $A \in \mathcal{S}$ then $\mu_+(A) = \mu(A \cap P) = [\nu_+(A \cap P) - \nu_-(A \cap P)] = \nu_+(A \cap P)$. But also $\nu_+(A) = \nu_+(A \cap P) + \nu_+(A \cap P^c) = \nu_+(A \cap P)$. Hence $\nu_+ = \mu_+$ and therefore also $\nu_- = \mu_-$.

The Jordan decomposition leads to an important set of new definitions.

Suppose that μ has Jordan decomposition $\mu = \mu_+ - \mu_-$.

1. The positive measure μ_+ is called the *positive variation measure* of μ .
2. The positive measure μ_- is called the *negative variation measure* of μ .

3. The positive measure $|\mu| = \mu_+ + \mu_-$ is called the *total variation measure* of μ .
4. $\|\mu\| = |\mu|(S)$ is the *total variation* of μ .

Note that, in spite of the similarity in notation, $\mu_+(A)$ and $\mu_-(A)$ are *not* simply the positive and negative parts of the (extended) real number $\mu(A)$, nor is $|\mu|(A)$ the absolute value of $\mu(A)$. Also, be careful not to confuse the total variation of μ , a number in $[0, \infty]$, with the total variation *measure*. The positive, negative, and total variation measures can be written directly in terms of μ .

For $A \in \mathcal{S}$,

1. $\mu_+(A) = \sup\{\mu(B) : B \in \mathcal{S}, B \subseteq A\}$
2. $\mu_-(A) = -\inf\{\mu(B) : B \in \mathcal{S}, B \subseteq A\}$
3. $|\mu|(A) = \sup\left\{\sum_{i \in I} \mu(A_i) : \{A_i : i \in I\} \text{ is a finite, measurable partition of } A\right\}$
4. $\|\mu\| = \sup\left\{\sum_{i \in I} \mu(A_i) : \{A_i : i \in I\} \text{ is a finite, measurable partition of } S\right\}$

The total variation measure is related to sum and scalar multiples of measures in a natural way.

Suppose that μ and ν are measures of the same type and that $c \in \mathbb{R}$. Then

1. $|\mu| = 0$ if and only if $\mu = 0$ (the zero measure).
2. $|c\mu| = |c| |\mu|$
3. $|\mu + \nu| \leq |\mu| + |\nu|$

Proof

1. Since μ_+ , μ_- and $|\mu| = \mu_+ + \mu_-$ are positive measures, $|\mu| = 0$ if and only if $\mu_+ = \mu_- = 0$ if and only if $\mu = 0$.
2. If $c > 0$ then $(c\mu)_+ = c\mu_+$ and $(c\mu)_- = c\mu_-$. If $c < 0$ then $(c\mu)_+ = -c\mu_-$ and $(c\mu)_- = -c\mu_+$. Of course, if $c = 0$ then $(c\mu)_+ = (c\mu)_- = 0$. In all cases,

$$|c\mu| = (c\mu)_+ + (c\mu)_- = |c|(\mu_+ + \mu_-) = |c| |\mu| \quad (3.12.13)$$

3. From the [theorem above](#), $(\mu + \nu)_+ \leq \mu_+ + \nu_+$ and $(\mu + \nu)_- \leq \mu_- + \nu_-$. So

$$\begin{aligned} |\mu + \nu| &= (\mu + \nu)_+ + (\mu + \nu)_- \leq (\mu_+ + \nu_+) + (\mu_- + \nu_-) \\ &= (\mu_+ + \mu_-) + (\nu_+ + \nu_-) = |\mu| + |\nu| \end{aligned}$$

You may have noticed that the properties in the last result look a bit like norm properties. In fact, total variation really is a norm on the vector space of finite measures on (S, \mathcal{S}) :

Suppose that μ and ν are measures of the same type and that $c \in \mathbb{R}$. Then

1. $\|\mu\| = 0$ if and only if $\mu = 0$ (the *zero property*)
2. $\|c\mu\| = |c| \|\mu\|$ (the *scaling property*)
3. $\|\mu + \nu\| \leq \|\mu\| + \|\nu\|$ (the *triangle inequality*)

Proof

1. Since $|\mu|$ is a positive measure, $\|\mu\| = |\mu|(S) = 0$ if and only if $|\mu| = 0$. From part (a) of the [previous theorem](#), $|\mu| = 0$ if and only if $\mu = 0$.
2. From part (b) of the [previous theorem](#), $\|c\mu\| = |c\mu|(S) = |c| |\mu|(S) = |c| \|\mu\|$.
3. From part (c) of the [previous theorem](#), $\|\mu + \nu\| = |\mu + \nu|(S) \leq |\mu|(S) + |\nu|(S) = \|\mu\| + \|\nu\|$.

Every norm on a vector space leads to a corresponding measure of distance (a metric). Let \mathcal{M} denote the collection of finite measures on (S, \mathcal{S}) . Then \mathcal{M} , under the usual definition of addition and scalar multiplication of measures, is a vector space, and as the last theorem shows, $\|\cdot\|$ is a norm on \mathcal{M} . Here are the corresponding metric space properties:

Suppose that $\mu, \nu, \rho \in \mathcal{M}$ and $c \in \mathbb{R}$. Then

1. $\|\mu - \nu\| = \|\nu - \mu\|$, the *symmetric property*
2. $\|\mu\| = 0$ if and only if $\mu = 0$, the *zero property*
3. $\|\mu - \rho\| \leq \|\mu - \nu\| + \|\nu - \rho\|$, the *triangle inequality*

Now that we have a metric, we have a corresponding criterion for convergence.

Suppose that $\mu_n \in \mathcal{M}$ for $n \in \mathbb{N}_+$ and $\mu \in \mathcal{M}$. We say that $\mu_n \rightarrow \mu$ as $n \rightarrow \infty$ in *total variation* if $\|\mu_n - \mu\| \rightarrow 0$ as $n \rightarrow \infty$.

Of course, \mathcal{M} includes the probability measures on (S, \mathcal{S}) , so we have a new notion of convergence to go along with the others we have studied or will study. Here is a list:

- convergence with probability 1
- convergence in probability
- convergence in distribution
- convergence in k th mean
- convergence in total variation

The Integral

Armed with the Jordan decomposition, the integral can be extended to general measures in a natural way.

Suppose that μ is a measure on (S, \mathcal{S}) and that $f : S \rightarrow \mathbb{R}$ is measurable. We define

$$\int_S f d\mu = \int_S f d\mu_+ - \int_S f d\mu_- \quad (3.12.14)$$

assuming that the integrals on the right exist and that the right side is not of the form $\infty - \infty$.

We will not pursue this extension, but as you might guess, the essential properties of the integral hold.

Complex Measures

Again, suppose that (S, \mathcal{S}) is a measurable space. The same axioms that work for general measures can be used to define complex measures. Recall that $\mathbb{C} = \{x + iy : x, y \in \mathbb{R}\}$ denotes the set of complex numbers, where i is the imaginary unit.

A *complex measure* on (S, \mathcal{S}) is a function $\mu : \mathcal{S} \rightarrow \mathbb{C}$ that satisfies the following properties:

1. $\mu(\emptyset) = 0$
2. If $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} then $\mu(\bigcup_{i \in I} A_i) = \sum_{i \in I} \mu(A_i)$

Clearly a complex measure μ can be decomposed as $\mu = \nu + i\rho$ where ν and ρ are finite (real) measures on (S, \mathcal{S}) . We will have no use for complex measures in this text, but from the decomposition into finite measures, it's easy to see how to develop the theory.

Computational Exercises

Counterexamples

The [lemma](#) needed for the Hahn decomposition theorem can fail without the assumption that $\mu(A) < \infty$.

Let S be a set with subsets A and B satisfying $\emptyset \subset B \subset A \subset S$. Let $\mathcal{S} = \sigma\{A, B\}$ be the σ -algebra generated by $\{A, B\}$. Define $\mu(B) = -1$, $\mu(A \setminus B) = \infty$, $\mu(A^c) = 1$.

1. Draw the Venn diagram of A, B, S .
2. List the sets in \mathcal{S} .
3. Using additivity, give the value of μ on each set in \mathcal{S} .
4. Show that A does not have a positive subset $P \in \mathcal{S}$ with $\mu(P) \geq \mu(A)$.

This page titled [3.12: General Measures](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist \(Random Services\)](#) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

3.13: Absolute Continuity and Density Functions

Basic Theory

Our starting point is a measurable space (S, \mathcal{S}) . That is S is a set and \mathcal{S} is a σ -algebra of subsets of S . In the last section, we discussed general measures on (S, \mathcal{S}) that can take positive and negative values. Special cases are positive measures, finite measures, and our favorite kind, probability measures. In particular, we studied properties of general measures, ways to construct them, special sets (positive, negative, and null), and the Hahn and Jordan decompositions.

In this section, we see how to construct a new measure from a given positive measure using a density function, and we answer the fundamental question of when a measure has a density function relative to the given positive measure.

Relations on Measures

The answer to the question involves two important relations on the collection of measures on (S, \mathcal{S}) that are defined in terms of null sets. Recall that $A \in \mathcal{S}$ is *null* for a measure μ on (S, \mathcal{S}) if $\mu(B) = 0$ for every $B \in \mathcal{S}$ with $B \subseteq A$. At the other extreme, $A \in \mathcal{S}$ is a *support set* for μ if A^c is a null set. Here are the basic definitions:

Suppose that μ and ν are measures on (S, \mathcal{S}) .

1. ν is *absolutely continuous* with respect to μ if every null set of μ is also a null set of ν . We write $\nu \ll \mu$.
2. μ and ν are *mutually singular* if there exists $A \in \mathcal{S}$ such that A is null for μ and A^c is null for ν . We write $\mu \perp \nu$.

Thus $\nu \ll \mu$ if every support set of μ is a support set of ν . At the opposite end, $\mu \perp \nu$ if μ and ν have disjoint support sets.

Suppose that μ, ν , and ρ are measures on (S, \mathcal{S}) . Then

1. $\mu \ll \mu$, the *reflexive property*.
2. If $\mu \ll \nu$ and $\nu \ll \rho$ then $\mu \ll \rho$, the *transitive property*.

Recall that every relation that is reflexive and transitive leads to an equivalence relation, and then in turn, the original relation can be extended to a partial order on the collection of equivalence classes. This general theorem on relations leads to the following two results.

Measures μ and ν on (S, \mathcal{S}) are *equivalent* if $\mu \ll \nu$ and $\nu \ll \mu$, and we write $\mu \equiv \nu$. The relation \equiv is an equivalence relation on the collection of measures on (S, \mathcal{S}) . That is, if μ, ν , and ρ are measures on (S, \mathcal{S}) then

1. $\mu \equiv \mu$, the *reflexive property*
2. If $\mu \equiv \nu$ then $\nu \equiv \mu$, the *symmetric property*
3. If $\mu \equiv \nu$ and $\nu \equiv \rho$ then $\mu \equiv \rho$, the *transitive property*

Thus, μ and ν are equivalent if they have the same null sets and thus the same support sets. This equivalence relation is rather weak: equivalent measures have the same support sets, but the values assigned to these sets can be very different. As usual, we will write $[\mu]$ for the equivalence class of a measure μ on (S, \mathcal{S}) , under the equivalence relation \equiv .

If μ and ν are measures on (S, \mathcal{S}) , we write $[\mu] \preceq [\nu]$ if $\mu \ll \nu$. The definition is consistent, and defines a partial order on the collection of equivalence classes. That is, if μ, ν , and ρ are measures on (S, \mathcal{S}) then

1. $[\mu] \preceq [\mu]$, the *reflexive property*.
2. If $[\mu] \preceq [\nu]$ and $[\nu] \preceq [\mu]$ then $[\mu] = [\nu]$, the *antisymmetric property*.
3. If $[\mu] \preceq [\nu]$ and $[\nu] \preceq [\rho]$ then $[\mu] \preceq [\rho]$, the *transitive property*

The singularity relation is trivially symmetric and is almost anti-reflexive.

Suppose that μ and ν are measures on (S, \mathcal{S}) . Then

1. If $\mu \perp \nu$ then $\nu \perp \mu$, the *symmetric property*.
2. $\mu \perp \mu$ if and only if $\mu = \mathbf{0}$, the *zero measure*.

Proof

Part (a) is trivial from the symmetry of the definition. For part (b), note that S is null for $\mathbf{0}$ and \emptyset is null for $\mathbf{0}$, so $\mathbf{0} \perp \mathbf{0}$. Conversely, suppose that μ is a measure and $\mu \perp \mu$. Then there exists $A \in \mathcal{S}$ such that A is null for μ and A^c is null for μ . But then $S = A \cup A^c$ is null for μ , so $\mu(B) = 0$ for every $B \in \mathcal{S}$.

Absolute continuity and singularity are preserved under multiplication by nonzero constants.

Suppose that μ and ν are measures on (S, \mathcal{S}) and that $a, b \in \mathbb{R} \setminus \{0\}$. Then

1. $\nu \ll \mu$ if and only if $a\nu \ll b\mu$.
2. $\nu \perp \mu$ if and only if $a\nu \perp b\mu$.

Proof

Recall that if $c \neq 0$, then $A \in \mathcal{S}$ is null for μ if and only if A is null for $c\mu$.

There is a corresponding result for sums of measures.

Suppose that μ is a measure on (S, \mathcal{S}) and that ν_i is a measure on (S, \mathcal{S}) for each i in a countable index set I . Suppose also that $\nu = \sum_{i \in I} \nu_i$ is a well-defined measure on (S, \mathcal{S}) .

1. If $\nu_i \ll \mu$ for every $i \in I$ then $\nu \ll \mu$.
2. If $\nu_i \perp \mu$ for every $i \in I$ then $\nu \perp \mu$.

Proof

Recall that if $A \in \mathcal{S}$ is null for ν_i for each $i \in I$, then A is null for $\nu = \sum_{i \in I} \nu_i$, assuming that this is a well-defined measure.

As before, note that $\nu = \sum_{i \in I} \nu_i$ is well-defined if ν_i is a positive measure for each $i \in I$ or if I is finite and ν_i is a finite measure for each $i \in I$. We close this subsection with a couple of results that involve both the absolute continuity relation and the singularity relation

Suppose that μ, ν , and ρ are measures on (S, \mathcal{S}) . If $\nu \ll \mu$ and $\mu \perp \rho$ then $\nu \perp \rho$.

Proof

Since $\mu \perp \rho$, there exists $A \in \mathcal{S}$ such that A is null for μ and A^c is null for ρ . But $\nu \ll \mu$ so A is null for ν . Hence $\nu \perp \rho$.

Suppose that μ and ν are measures on (S, \mathcal{S}) . If $\nu \ll \mu$ and $\nu \perp \mu$ then $\nu = \mathbf{0}$.

Proof

From the [previous theorem](#) (with $\rho = \nu$) we have $\nu \perp \nu$ and hence by (5), $\nu = \mathbf{0}$.

Density Functions

We are now ready for our study of density functions. Throughout this subsection, we assume that μ is a positive, σ -finite measure on our measurable space (S, \mathcal{S}) . Recall that if $f: S \rightarrow \mathbb{R}$ is measurable, then the integral of f with respect to μ may exist as a number in $\mathbb{R}^* = \mathbb{R} \cup \{-\infty, \infty\}$ or may fail to exist.

Suppose that $f: S \rightarrow \mathbb{R}$ is a measurable function whose integral with respect to μ exists. Then function ν defined by

$$\nu(A) = \int_A f d\mu, \quad A \in \mathcal{S} \quad (3.13.1)$$

is a σ -finite measure on (S, \mathcal{S}) that is absolutely continuous with respect to μ . The function f is a *density function* of ν relative to μ .

Proof

To say that the integral exists means that either $\int_S f^+ d\mu < \infty$ or $\int_S f^- d\mu < \infty$, where as usual, f^+ and f^- are the positive and negative parts of f . So $\nu(A) = \nu_+(A) - \nu_-(A)$ for $A \in \mathcal{S}$ where $\nu_+(A) = \int_A f^+ d\mu$ and $\nu_-(A) = \int_A f^- d\mu$. Both ν_+ and ν_- are positive measures by basic properties of the integral: Generically, suppose $g: S \rightarrow [0, \infty)$ is measurable. The integral over the empty set is always 0, so $\int_\emptyset g d\mu = 0$. Next, if $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} and $A = \bigcup_{i \in I} A_i$, then by the additivity property of the integral over disjoint domains,

$$\int_A g d\mu = \sum_{i \in I} \int_{A_i} g d\mu \quad (3.13.2)$$

By the assumption that the integral exists, either ν_+ or ν_- is a finite positive measure, and hence ν is a measure. As you might guess, ν_+ and ν_- form the Jordan decomposition of ν , a point that we will revisit below.

Again, either ν_+ or ν_- is a finite measure. By symmetry, let's suppose that ν_- is finite. Then to show that ν is σ -finite, we just need to show that ν_+ is σ -finite. Since μ has this property, there exists a collection $\{A_n : n \in \mathbb{N}_+\}$ with $A_n \in \mathcal{S}$, $\mu(A_n) < \infty$, and $\bigcup_{n=1}^\infty A_n = S$. Let $B_n = \{x \in S : f^+(x) \leq n\}$ for $n \in \mathbb{N}_+$. Then $B_n \in \mathcal{S}$ for $n \in \mathbb{N}_+$ and $\bigcup_{n=1}^\infty B_n = S$. Hence $\{A_m \cap B_n : (m, n) \in \mathbb{N}_+^2\}$ is a countable collection of measurable sets whose union is also S . Moreover,

$$\nu_+(A_m \cap B_n) = \int_{A_m \cap B_n} f^+ d\mu \leq n\mu(A_m \cap B_n) < \infty \quad (3.13.3)$$

Finally, suppose $A \in \mathcal{S}$ is a null set of μ . If $B \in \mathcal{S}$ and $B \subseteq A$ then $\mu(B) = 0$ so $\nu(B) = \int_B f d\mu = 0$. Hence $\nu \ll \mu$.

The following three special cases are the most important:

1. If f is nonnegative (so that the integral exists in $\mathbb{R} \cup \{\infty\}$) then ν is a *positive measure* since $\nu(A) \geq 0$ for $A \in \mathcal{S}$.
2. If f is integrable (so that the integral exists in \mathbb{R}), then ν is a *finite measure* since $\nu(A) \in \mathbb{R}$ for $A \in \mathcal{S}$.
3. If f is nonnegative and $\int_S f d\mu = 1$ then ν is a *probability measure* since $\nu(A) \geq 0$ for $A \in \mathcal{S}$ and $\nu(S) = 1$.

In case 3, f is the *probability density function* of ν relative to μ , our favorite kind of density function. When they exist, density functions are essentially unique.

Suppose that ν is a σ -finite measure on (S, \mathcal{S}) and that ν has density function f with respect to μ . Then $g: S \rightarrow \mathbb{R}$ is a density function of ν with respect to μ if and only if $f = g$ almost everywhere on S with respect to μ .

Proof

These results also follow from basic properties of the integral. Suppose that $f, g: S \rightarrow \mathbb{R}$ are measurable functions whose integrals with respect to μ exist. If $g = f$ almost everywhere on S with respect to μ then $\int_A f d\mu = \int_A g d\mu$ for every $A \in \mathcal{S}$. Hence if f is a density function for ν with respect to μ then so is g . For the converse, if $\int_A f d\mu = \int_A g d\mu$ for every $A \in \mathcal{S}$, then since μ is σ -finite, it follows that $f = g$ almost everywhere on S with respect to μ .

The essential uniqueness of density functions can fail if the positive measure space (S, \mathcal{S}, μ) is not σ -finite. A simple example is given [below](#). Our next result answers the question of when a measure has a density function with respect to μ , and is the fundamental theorem of this section. The theorem is in two parts: Part (a) is the *Lebesgue decomposition theorem*, named for our old friend Henri Lebesgue. Part (b) is the *Radon-Nikodym theorem*, named for Johann Radon and Otto Nikodym. We combine the theorems because our proofs of the two results are inextricably linked.

Suppose that ν is a σ -finite measure on (S, \mathcal{S}) .

1. **Lebesgue Decomposition Theorem.** ν can be uniquely decomposed as $\nu = \nu_c + \nu_s$ where $\nu_c \ll \mu$ and $\nu_s \perp \mu$.
2. **Radon-Nikodym Theorem.** ν_c has a density function with respect to μ .

Proof

The proof proceeds in stages. we first prove the result for finite, positive measures, then for σ -finite, positive measures, and finally for general σ -finite measures. The first stage is the most complicated.

Part 1, suppose that μ and ν are positive, finite measures. Let \mathcal{F} denote the collection of measurable functions $g: S \rightarrow [0, \infty)$ with $\int_A g d\mu \leq \nu(A)$ for all $A \in \mathcal{S}$. Note that $\mathcal{F} \neq \emptyset$ since the constant function 0 is in \mathcal{F} . The proof works by finding a maximal element of \mathcal{F} and using this function as the density function of the absolutely continuous part of ν .

Our first step is to show that \mathcal{F} is closed under the max operator. Let $g_1, g_2 \in \mathcal{F}$. For $A \in \mathcal{S}$, let $A_1 = \{x \in A : g_1(x) \geq g_2(x)\}$ and $A_2 = \{x \in A : g_1(x) < g_2(x)\}$. Then $A_1, A_2 \in \mathcal{S}$ partition A so

$$\int_A \max\{g_1, g_2\} d\mu = \int_{A_1} \max\{g_1, g_2\} d\mu + \int_{A_2} \max\{g_1, g_2\} d\mu = \int_{A_1} g_1 d\mu + \int_{A_2} g_2 d\mu \leq \nu(A_1) + \nu(A_2) = \nu(A) \quad (3.13.4)$$

Hence $\max\{g_1, g_2\} \in \mathcal{F}$.

Our next step is to show that \mathcal{F} is closed with respect to increasing limits. Thus suppose that $g_n \in \mathcal{F}$ for $n \in \mathbb{N}_+$ and that g_n is increasing in n on S . Let $g = \lim_{n \rightarrow \infty} g_n$. Then $g: S \rightarrow [0, \infty]$ is measurable, and by the monotone convergence theorem, $\int_A g d\mu = \lim_{n \rightarrow \infty} \int_A g_n d\mu$ for every $A \in \mathcal{S}$. But $\int_A g_n d\mu \leq \nu(A)$ for every $n \in \mathbb{N}_+$ so $\int_A g d\mu \leq \nu(A)$. In particular, $\int_S g d\mu \leq \nu(S) < \infty$ so $g < \infty$ almost everywhere on S with respect to μ . Thus, by redefining g on a μ -null set if necessary, we can assume $g < \infty$ on S . Hence $g \in \mathcal{F}$.

Now let $\alpha = \sup \left\{ \int_S g d\mu : g \in \mathcal{F} \right\}$. Note that $\alpha \leq \nu(S) < \infty$. By definition of the supremum, for each $n \in \mathbb{N}_+$ there exist $g_n \in \mathcal{F}$ such that $\int_S g_n d\mu > \alpha - \frac{1}{n}$. Now let $f_n = \max\{g_1, g_2, \dots, g_n\}$ for $n \in \mathbb{N}_+$. Then $f_n \in \mathcal{F}$ and f_n is increasing in $n \in \mathbb{N}_+$ on S . Hence $f = \lim_{n \rightarrow \infty} f_n \in \mathcal{F}$ and $\int_S f d\mu = \lim_{n \rightarrow \infty} \int_S f_n d\mu$. But $\int_S f_n d\mu \geq \int_S g_n d\mu > \alpha - \frac{1}{n}$ for each $n \in \mathbb{N}_+$ and hence $\int_S f d\mu \geq \alpha$.

Define $\nu_c(A) = \int_A f d\mu$ and $\nu_s(A) = \nu(A) - \nu_c(A)$ for $A \in \mathcal{S}$. Then ν_c and ν_s are finite, positive measures and by our previous theorem, ν_c is absolutely continuous with respect to μ and has density function f . Our next step is to show that ν_s is singular with respect to μ . For $n \in \mathbb{N}$, let (P_n, P_n^c) denote a Hahn decomposition of the measure $\nu_s - \frac{1}{n}\mu$. Then

$$\int_A \left(f + \frac{1}{n} \mathbf{1}_{P_n} \right) d\mu = \nu_c(A) + \frac{1}{n} \mu(P_n \cap A) = \nu(A) - \left[\nu_s(A) - \frac{1}{n} \mu(P_n \cap A) \right] \quad (3.13.5)$$

But $\nu_s(A) - \frac{1}{n}\mu(P_n \cap A) \geq \nu_s(A \cap P_n) - \frac{1}{n}\mu(A \cap P_n) \geq 0$ since ν_s is a positive measure and P_n is positive for $\nu_s - \frac{1}{n}\mu$. Thus we have $\int_A (f + \frac{1}{n}\mathbf{1}_{P_n}) d\mu \leq \nu(A)$ for every $A \in \mathcal{S}$, so $f + \frac{1}{n}\mathbf{1}_{P_n} \in \mathcal{F}$ for every $n \in \mathbb{N}_+$. If $\mu(P_n) > 0$ then $\int_S (f + \frac{1}{n}\mathbf{1}_{P_n}) d\mu = \alpha + \frac{1}{n}\mu(P_n) > \alpha$, which contradicts the definition of α . Hence we must have $\mu(P_n) = 0$ for every $n \in \mathbb{N}_+$. Now let $P = \bigcup_{n=1}^{\infty} P_n$. Then $\mu(P) = 0$. If $\nu_s(P^c) > 0$ then $\nu_s(P^c) - \frac{1}{n}\mu(P^c) > 0$ for n sufficiently large. But this is a contradiction since $P^c \subseteq P_n^c$ which is negative for $\nu_s - \frac{1}{n}\mu$ for every $n \in \mathbb{N}_+$. Thus we must have $\nu_s(P^c) = 0$, so μ and ν_s are singular.

Part 2. Suppose that μ and ν are σ -finite, positive measures. Then there exists a countable partition $\{S_i : i \in I\}$ of S where $S_i \in \mathcal{S}$ for $i \in I$, and $\mu(S_i) < \infty$ and $\nu(S_i) < \infty$ for $i \in I$. Let $\mu_i(A) = \mu(A \cap S_i)$ and $\nu_i(A) = \nu(A \cap S_i)$ for $i \in I$. Then μ_i and ν_i are finite, positive measures for $i \in I$, and $\mu = \sum_{i \in I} \mu_i$ and $\nu = \sum_{i \in I} \nu_i$. By part 1, for each $i \in I$, there exists a measurable function $f_i : S \rightarrow [0, \infty)$ such that $\nu_i = \nu_{i,c} + \nu_{i,s}$ where $\nu_{i,c}(A) = \int_A f_i d\mu$ for $A \in \mathcal{S}$ and $\nu_{i,s} \perp \mu$. Let $f = \sum_{i \in I} \mathbf{1}_{A_i} f_i$. Then $f : S \rightarrow [0, \infty)$ is measurable. Define $\nu_c(A) = \int_A f d\mu$ and $\nu_s(A) = \nu(A) - \nu_c(A)$ for $A \in \mathcal{S}$. Note that $\nu_c = \sum_{i \in I} \nu_{i,c}$ and $\nu_s = \sum_{i \in I} \nu_{i,s}$. Then $\nu_c \ll \mu$ and has density function f and $\nu_s \perp \mu$.

Part 3. Suppose that ν is a σ -finite measure (not necessarily positive). By the Jordan decomposition theorem, $\nu = \nu_+ - \nu_-$ where ν_+ and ν_- are σ -finite, positive measures, and at least one is finite. By part 2, there exist measurable functions $f_+ : S \rightarrow [0, \infty)$ and $f_- : S \rightarrow [0, \infty)$ such that $\nu_+ = \nu_{+,c} + \nu_{+,s}$ and $\nu_- = \nu_{-,c} + \nu_{-,s}$ where $\nu_{+,c}(A) = \int_A f_+ d\mu$, $\nu_{-,c}(A) = \int_A f_- d\mu$ for $A \in \mathcal{S}$, and $\nu_{+,s} \perp \mu$, $\nu_{-,s} \perp \mu$. Let $f = f_+ - f_-$, $\nu_c(A) = \int_A f d\mu$, $\nu_s(A) = \nu(A) - \nu_c(A)$ for $A \in \mathcal{S}$. Then $\nu = \nu_c + \nu_s$ and $\nu_s = \nu_{+,s} - \nu_{-,s} \perp \mu$.

Uniqueness. Suppose that $\nu = \nu_{c,1} + \nu_{s,1} = \nu_{c,2} + \nu_{s,2}$ where $\nu_{c,i} \ll \mu$ and $\nu_{s,i} \perp \mu$ for $i \in \{1, 2\}$. Then $\nu_{c,1} - \nu_{c,2} = \nu_{s,2} - \nu_{s,1}$. But $\nu_{c,1} - \nu_{c,2} \ll \mu$ and $\nu_{s,2} - \nu_{s,1} \perp \mu$ so $\nu_{c,1} - \nu_{c,2} = \nu_{s,2} - \nu_{s,1} = \mathbf{0}$ by the theorem above.

In particular, a measure ν on (S, \mathcal{S}) has a density function with respect to μ if and only if $\nu \ll \mu$. The density function in this case is also referred to as the *Radon-Nikodym derivative* of ν with respect to μ and is sometimes written in derivative notation as $d\nu/d\mu$. This notation, however, can be a bit misleading because we need to remember that a density function is unique only up to a μ -null set. Also, the Radon-Nikodym theorem can fail if the positive measure space (S, \mathcal{S}, μ) is not σ -finite. A couple of examples are given below. Next we characterize the Hahn decomposition and the Jordan decomposition of ν in terms of the density function.

Suppose that ν is a measure on (S, \mathcal{S}) with $\nu \ll \mu$, and that ν has density function f with respect to μ . Let $P = \{x \in S : f(x) \geq 0\}$, and let f^+ and f^- denote the positive and negative parts of f .

1. A Hahn decomposition of ν is (P, P^c) .
2. The Jordan decomposition is $\nu = \nu_+ - \nu_-$ where $\nu_+(A) = \int_A f^+ d\mu$ and $\nu_-(A) = \int_A f^- d\mu$, for $A \in \mathcal{S}$.

Proof

Of course $P^c = \{x \in S : f(x) < 0\}$. The proofs are simple.

1. Suppose that $A \in \mathcal{S}$. If $A \subseteq P$ then $f(x) \geq 0$ for $x \in A$ and hence $\nu(A) = \int_A f d\mu \geq 0$. If $A \subseteq P^c$ then $\nu(A) = \int_A f d\mu \leq 0$.
2. This follows immediately from (a) and the Jordan decomposition theorem, since $\nu_+(A) = \nu(A \cap P)$ and $\nu_-(A) = -\nu(A \cap P^c)$ for $A \in \mathcal{S}$. Note that $f^+ = \mathbf{1}_P f$ and $f^- = -\mathbf{1}_{P^c} f$.

The following result is a basic *change of variables theorem* for integrals.

Suppose that ν is a positive measure on (S, \mathcal{S}) with $\nu \ll \mu$ and that ν has density function f with respect to μ . If $g : S \rightarrow \mathbb{R}$ is a measurable function whose integral with respect to ν exists, then

$$\int_S g d\nu = \int_S g f d\mu \quad (3.13.6)$$

Proof

The proof is a classical *bootstrapping argument*. Suppose first that $g = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ is a nonnegative simple function. That is, I is a finite index set, $a_i \in [0, \infty)$ for $i \in I$, and $\{A_i : i \in I\}$ is a disjoint collection of sets in \mathcal{S} . Then $\int_S g d\nu = \sum_{i \in I} a_i \nu(A_i)$. But $\nu(A_i) = \int_{A_i} f d\mu = \int_S \mathbf{1}_{A_i} f d\mu$ for each $i \in I$ so

$$\int_S g d\mu = \sum_{i \in I} a_i \int_S \mathbf{1}_{A_i} f d\mu = \int_S \left(\sum_{i \in I} a_i \mathbf{1}_{A_i} \right) f d\mu = \int_S g f d\mu \quad (3.13.7)$$

Suppose next that $g : S \rightarrow [0, \infty)$ is measurable. There exists a sequence of nonnegative simple functions (g_1, g_2, \dots) such that g_n is increasing in $n \in \mathbb{N}_+$ on S and $g_n \rightarrow g$ as $n \rightarrow \infty$ on S . Since f is nonnegative, $g_n f$ is increasing in $n \in \mathbb{N}_+$ on S and $g_n f \rightarrow g f$ as $n \rightarrow \infty$ on S . By the first step, $\int_S g_n d\nu = \int_S g_n f d\mu$ for each $n \in \mathbb{N}_+$. But by the monotone convergence theorem, $\int_S g_n d\nu \rightarrow \int_S g d\nu$ and $\int_S g_n f d\mu \rightarrow \int_S g f d\mu$ as $n \rightarrow \infty$. Hence $\int_S g d\nu = \int_S g f d\mu$.

Finally, suppose that $g: S \rightarrow \mathbb{R}$ is a measurable function whose integral with respect to ν exists. By the previous step, $\int_S g^+ d\nu = \int_S g^+ f d\mu$ and $\int_S g^- d\nu = \int_S g^- f d\mu$, and at least one of these integrals is finite. Hence by the additive property

$$\int_S g d\nu = \int_S g^+ d\nu - \int_S g^- d\nu = \int_S g^+ f d\mu - \int_S g^- f d\mu = \int_S (g^+ - g^-) f d\mu = \int_S g f d\mu \quad (3.13.8)$$

In *differential notation*, the change of variables theorem has the familiar form $d\nu = f d\mu$, and this is really the justification for the derivative notation $f = d\nu/d\mu$ in the first place. The following result gives the *scalar multiple rule* for density functions.

Suppose that ν is a measure on (S, \mathcal{S}) with $\nu \ll \mu$ and that ν has density function f with respect to μ . If $c \in \mathbb{R}$, then $c\nu$ has density function cf with respect to μ .

Proof

If $A \in \mathcal{S}$ then $\int_A cf d\mu = c \int_A f d\mu = c\nu(A)$.

Of course, we already knew that $\nu \ll \mu$ implies $c\nu \ll \mu$ for $c \in \mathbb{R}$, so the new information is the relation between the density functions. In derivative notation, the scalar multiple rule has the familiar form

$$\frac{d(c\nu)}{d\mu} = c \frac{d\nu}{d\mu} \quad (3.13.9)$$

The following result gives the sum rule for density functions. Recall that two measures are of the *same type* if neither takes the value ∞ or if neither takes the value $-\infty$.

Suppose that ν and ρ are measures on (S, \mathcal{S}) of the same type with $\nu \ll \mu$ and $\rho \ll \mu$, and that ν and ρ have density functions f and g with respect to μ , respectively. Then $\nu + \rho$ has density function $f + g$ with respect to μ .

Proof

If $A \in \mathcal{S}$ then

$$\int_A (f + g) d\mu = \int_A f d\mu + \int_A g d\mu = \nu(A) + \rho(A) \quad (3.13.10)$$

The additive property holds because we know that the integrals in the middle of the displayed equation are not of the form $\infty - \infty$.

Of course, we already knew that $\nu \ll \mu$ and $\rho \ll \mu$ imply $\nu + \rho \ll \mu$, so the new information is the relation between the density functions. In derivative notation, the sum rule has the familiar form

$$\frac{d(\nu + \rho)}{d\mu} = \frac{d\nu}{d\mu} + \frac{d\rho}{d\mu} \quad (3.13.11)$$

The following result is the *chain rule* for density functions.

Suppose that ν is a positive measure on (S, \mathcal{S}) with $\nu \ll \mu$ and that ν has density function f with respect to μ . Suppose ρ is a measure on (S, \mathcal{S}) with $\rho \ll \nu$ and that ρ has density function g with respect to ν . Then ρ has density function gf with respect to μ .

Proof

This is a simple consequence of the change of variables theorem above. If $A \in \mathcal{S}$ then $\rho(A) = \int_A g d\nu = \int_A gf d\mu$.

Of course, we already knew that $\nu \ll \mu$ and $\rho \ll \nu$ imply $\rho \ll \mu$, so once again the new information is the relation between the density functions. In derivative notation, the chain rule has the familiar form

$$\frac{d\rho}{d\mu} = \frac{d\rho}{d\nu} \frac{d\nu}{d\mu} \quad (3.13.12)$$

The following related result is the *inverse rule* for density functions.

Suppose that ν is a positive measure on (S, \mathcal{S}) with $\nu \ll \mu$ and $\mu \ll \nu$ (so that $\nu \equiv \mu$). If ν has density function f with respect to μ then μ has density function $1/f$ with respect to ν .

Proof

Let f be a density function of ν with respect to μ and let $Z = \{x \in S : f(x) = 0\}$. Then $\nu(Z) = \int_Z f d\mu = 0$ so Z is a null set of ν and hence is also a null set of μ . Thus, we can assume that $f \neq 0$ on S . Let g be a density of μ with respect to ν . Since $\mu \ll \nu \ll \mu$, it follows from the chain rule that fg is a density of μ with respect to μ . But of course the constant function 1 is also a density of μ with respect to itself so we have $fg = 1$ almost everywhere on S . Thus $1/f$ is a density of μ with respect to ν .

In derivative notation, the inverse rule has the familiar form

$$\frac{d\mu}{d\nu} = \frac{1}{d\nu/d\mu} \quad (3.13.13)$$

Examples and Special Cases

Discrete Spaces

Recall that a *discrete measure space* $(S, \mathcal{S}, \#)$ consists of a countable set S with the σ -algebra $\mathcal{S} = \mathcal{P}(S)$ of all subsets of S , and with counting measure $\#$. Of course $\#$ is a positive measure and is trivially σ -finite since S is countable. Note also that \emptyset is the only set that is null for $\#$. If ν is a measure on S , then by definition, $\nu(\emptyset) = 0$, so ν is absolutely continuous relative to μ . Thus, by the Radon-Nikodym theorem, ν can be written in the form

$$\nu(A) = \sum_{x \in A} f(x), \quad A \subseteq S \quad (3.13.14)$$

for a unique $f : S \rightarrow \mathbb{R}$. Of course, this is obvious by a direct argument. If we define $f(x) = \nu\{x\}$ for $x \in S$ then the displayed equation follows by the countable additivity of ν .

Spaces Generated by Countable Partitions

We can generalize the last discussion to *spaces generated by countable partitions*. Suppose that S is a set and that $\mathcal{A} = \{A_i : i \in I\}$ is a countable partition of S into nonempty sets. Let $\mathcal{S} = \sigma(\mathcal{A})$ and recall that every $A \in \mathcal{S}$ has a unique representation of the form $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$. Suppose now that μ is a positive measure on \mathcal{S} with $0 < \mu(A_i) < \infty$ for every $i \in I$. Then once again, the measure space (S, \mathcal{S}, μ) is σ -finite and \emptyset is the only null set. Hence if ν is a measure on (S, \mathcal{S}) then ν is absolutely continuous with respect to μ and hence has unique density function f with respect to μ :

$$\nu(A) = \int_A f d\mu, \quad A \in \mathcal{S} \quad (3.13.15)$$

Once again, we can construct the density function explicitly.

In the setting above, define $f : S \rightarrow \mathbb{R}$ by $f(x) = \nu(A_i)/\mu(A_i)$ for $x \in A_i$ and $i \in I$. Then f is the density of ν with respect to μ .

Proof

Suppose that $A \in \mathcal{S}$ so that $A = \bigcup_{j \in J} A_j$ for some $J \subseteq I$. Then

$$\int_A f d\mu = \sum_{j \in J} \int_{A_j} f d\mu = \sum_{j \in J} \frac{\nu(A_j)}{\mu(A_j)} \mu(A_j) = \sum_{j \in J} \nu(A_j) = \nu(A) \quad (3.13.16)$$

Often positive measure spaces that occur in applications can be decomposed into spaces generated by countable partitions. In the section on Convergence in the chapter on Martingales, we show that more general density functions can be obtained as limits of density functions of the type in the [last theorem](#).

Probability Spaces

Suppose that $(\Omega, \mathcal{F}, \mathbb{P})$ is a probability space and that X is a random variable taking values in a measurable space (S, \mathcal{S}) . Recall that the *distribution* of X is the probability measure P_X on (S, \mathcal{S}) given by

$$P_X(A) = \mathbb{P}(X \in A), \quad A \in \mathcal{S} \quad (3.13.17)$$

If μ is a positive measure, σ -finite measure on (S, \mathcal{S}) , then the theory of this section applies, of course. The Radon-Nikodym theorem tells us precisely when (the distribution of) X has a probability density function with respect to μ : we need the distribution to be absolutely continuous with respect to μ : if $\mu(A) = 0$ then $P_X(A) = \mathbb{P}(X \in A) = 0$ for $A \in \mathcal{S}$.

Suppose that $r : S \rightarrow \mathbb{R}$ is measurable, so that $r(X)$ is a real-valued random variable. The integral of $r(X)$ (assuming that it exists) is of fundamental importance, and is known as the *expected value* of $r(X)$. We will study expected values in detail in the next chapter, but here we just note different ways to write the integral. By the change of variables theorem in the last section we have

$$\int_{\Omega} r[X(\omega)] d\mathbb{P}(\omega) = \int_S r(x) dP_X(x) \quad (3.13.18)$$

Assuming that P_X , the distribution of X , is absolutely continuous with respect to μ , with density function f , we can add to our chain of integrals using Theorem [\(14\)](#):

$$\int_{\Omega} r[X(\omega)] d\mathbb{P}(\omega) = \int_S r(x) dP_X(x) = \int_S r(x) f(x) d\mu(x) \quad (3.13.19)$$

Specializing, suppose that $(S, \mathcal{S}, \#)$ is a discrete measure space. Thus X has a discrete distribution and (as noted in the previous subsection), the distribution of X is absolutely continuous with respect to $\#$, with probability density function f given by $f(x) = \mathbb{P}(X = x)$ for $x \in S$. In this case the integral simplifies:

$$\int_{\Omega} r[X(\omega)] d\mathbb{P}(\omega) = \sum_{x \in S} r(x) f(x) \quad (3.13.20)$$

Recall next that for $n \in \mathbb{N}_+$, the n -dimensional Euclidean measure space is $(\mathbb{R}^n, \mathcal{R}_n, \lambda_n)$ where \mathcal{R}_n is the σ -algebra of Lebesgue measurable sets and λ_n is Lebesgue measure. Suppose now that $S \in \mathcal{R}_n$ and that \mathcal{S} is the σ -algebra of Lebesgue measurable subsets of S , and that once again, X is a random variable with values in S . By definition, X has a continuous distribution if $\mathbb{P}(X = x) = 0$ for $x \in S$. But we now know that this is not enough to ensure that the distribution of X has a density function with respect to λ_n . We need the distribution to be *absolutely* continuous, so that if $\lambda_n(A) = 0$ then $\mathbb{P}(X \in A) = 0$ for $A \in \mathcal{S}$. Of course $\lambda_n\{x\} = 0$ for $x \in S$, so absolute continuity implies continuity, but not conversely. Continuity of the distribution is a (much) weaker condition than absolute continuity of the distribution. If the distribution of X is continuous but not absolutely so, then the distribution will not have a density function with respect to λ_n .

For example, suppose that $\lambda_n(S) = 0$. Then the distribution of X and λ_n are mutually singular since $\mathbb{P}(X \in S) = 1$ and so X will not have a density function with respect to λ_n . This will always be the case if S is countable, so that the distribution of X is discrete. But it is also possible for X to have a continuous distribution on an uncountable set $S \in \mathcal{R}_n$ with $\lambda_n(S) = 0$. In such a case, the continuous distribution of X is said to be *degenerate*. There are a couple of natural ways in which this can happen that are illustrated in the following exercises.

Suppose that Θ is uniformly distributed on the interval $[0, 2\pi)$. Let $X = \cos \Theta$, $Y = \sin \Theta$.

1. (X, Y) has a continuous distribution on the circle $C = \{(x, y) : x^2 + y^2 = 1\}$.
2. The distribution of (X, Y) and λ_2 are mutually singular.
3. Find $\mathbb{P}(Y > X)$.

Solution

1. If $(x, y) \in C$ then there exist a unique $\theta \in [0, 2\pi)$ with $x = \cos \theta$ and $y = \sin \theta$. Hence $\mathbb{P}[(X, Y) = (x, y)] = \mathbb{P}(\Theta = \theta) = 0$.
2. $\mathbb{P}[(X, Y) \in C] = 1$ but $\lambda_2(C) = 0$.
3. $\frac{1}{2}$

The last example is artificial since (X, Y) has a one-dimensional distribution in a sense, in spite of taking values in \mathbb{R}^2 . And of course Θ has a probability density function f with respect to λ_1 given by $f(\theta) = 1/2\pi$ for $\theta \in [0, 2\pi)$.

Suppose that X is uniformly distributed on the set $\{0, 1, 2\}$, Y is uniformly distributed on the interval $[0, 2]$, and that X and Y are independent.

1. (X, Y) has a continuous distribution on the product set $S = \{0, 1, 2\} \times [0, 2]$.
2. The distribution of (X, Y) and λ_2 are mutually singular.
3. Find $\mathbb{P}(Y > X)$.

Solution

1. The variables are independent and Y has a continuous distribution so $\mathbb{P}[(X, Y) = (x, y)] = \mathbb{P}(X = 2)\mathbb{P}(Y = y) = 0$ for $(x, y) \in S$.
2. $\mathbb{P}[(X, Y) \in S] = 1$ but $\lambda_2(S) = 0$
3. $\frac{1}{2}$

The last exercise is artificial since X has a discrete distribution on $\{0, 1, 2\}$ (with all subsets measurable and with $\#$), and Y a continuous distribution on the Euclidean space $[0, 2]$ (with Lebesgue measurable subsets and with λ). Both are absolutely continuous; X has density function g given by $g(x) = 1/3$ for $x \in \{0, 1, 2\}$ and Y has density function h given by $h(y) = 1/2$ for $y \in [0, 2]$. So really, the proper measure space on S is the product measure space formed from these two spaces. Relative to this product space (X, Y) has a density f given by $f(x, y) = 1/6$ for $(x, y) \in S$.

It is also possible to have a continuous distribution on $S \subseteq \mathbb{R}^n$ with $\lambda_n(S) > 0$, yet still with no probability density function, a much more interesting situation. We will give a classical construction. Let (X_1, X_2, \dots) be a sequence of Bernoulli trials with success parameter $p \in (0, 1)$. We will indicate the dependence of the probability measure \mathbb{P} on the parameter p with a subscript. Thus, we have a sequence of independent indicator variables with

$$\mathbb{P}_p(X_i = 1) = p, \quad \mathbb{P}_p(X_i = 0) = 1 - p \quad (3.13.21)$$

We interpret X_i as the i th binary digit (*bit*) of a random variable X taking values in $(0, 1)$. That is, $X = \sum_{i=1}^{\infty} X_i/2^i$. Conversely, recall that every number $x \in (0, 1)$ can be written in binary form as $x = \sum_{i=1}^{\infty} x_i/2^i$ where $x_i \in \{0, 1\}$ for each $i \in \mathbb{N}_+$. This representation is unique

except when x is a *binary rational* of the form $x = k/2^n$ for $n \in \mathbb{N}_+$ and $k \in \{1, 3, \dots, 2^n - 1\}$. In this case, there are two representations, one in which the bits are eventually 0 and one in which the bits are eventually 1. Note, however, that the set of binary rationals is countable. Finally, note that the uniform distribution on $(0, 1)$ is the same as Lebesgue measure on $(0, 1)$.

X has a continuous distribution on $(0, 1)$ for every value of the parameter $p \in (0, 1)$. Moreover,

1. If $p, q \in (0, 1)$ and $p \neq q$ then the distribution of X with parameter p and the distribution of X with parameter q are mutually singular.
2. If $p = \frac{1}{2}$, X has the uniform distribution on $(0, 1)$.
3. If $p \neq \frac{1}{2}$, then the distribution of X is singular with respect to Lebesgue measure on $(0, 1)$, and hence has no probability density function in the usual sense.

Proof

If $x \in (0, 1)$ is not a binary rational, then

$$\mathbb{P}_p(X = x) = \mathbb{P}_p(X_i = x_i \text{ for all } i \in \mathbb{N}_+) = \lim_{n \rightarrow \infty} \mathbb{P}_p(X_i = x_i \text{ for } i = 1, 2, \dots, n) = \lim_{n \rightarrow \infty} p^y (1-p)^{n-y} \quad (3.13.22)$$

where $y = \sum_{i=1}^n x_i$. Let $q = \max\{p, 1-p\}$. Then $p^y (1-p)^{n-y} \leq q^n \rightarrow 0$ as $n \rightarrow \infty$. Hence, $\mathbb{P}_p(X = x) = 0$. If $x \in (0, 1)$ is a binary rational, then there are two bit strings that represent x , say (x_1, x_2, \dots) (with bits eventually 0) and (y_1, y_2, \dots) (with bits eventually 1). Hence $\mathbb{P}_p(X = x) = \mathbb{P}_p(X_i = x_i \text{ for all } i \in \mathbb{N}_+) + \mathbb{P}_p(X_i = y_i \text{ for all } i \in \mathbb{N}_+)$. But both of these probabilities are 0 by the same argument as before.

Next, we define the set of numbers for which the limiting relative frequency of 1's is p . Let $C_p = \{x \in (0, 1) : \frac{1}{n} \sum_{i=1}^n x_i \rightarrow p \text{ as } n \rightarrow \infty\}$. Note that since limits are unique, $C_p \cap C_q = \emptyset$ for $p \neq q$. Next, by the strong law of large numbers, $\mathbb{P}_p(X \in C_p) = 1$. Although we have not yet studied the law of large numbers, the basic idea is simple: in a sequence of Bernoulli trials with success probability p , the long-term relative frequency of successes is p . Thus the distributions of X , as p varies from 0 to 1, are mutually singular; that is, as p varies, X takes values with probability 1 in mutually disjoint sets.

Let F denote the distribution function of X , so that $F(x) = \mathbb{P}_p(X \leq x) = \mathbb{P}_p(X < x)$ for $x \in (0, 1)$. If $x \in (0, 1)$ is not a binary rational, then $X < x$ if and only if there exists $n \in \mathbb{N}_+$ such that $X_i = x_i$ for $i \in \{1, 2, \dots, n-1\}$ and $X_n = 0$ while $x_n = 1$. Hence $\mathbb{P}_{1/2}(X < x) = \sum_{n=1}^{\infty} \frac{x_n}{2^n} = x$. Since the distribution function of a continuous distribution is continuous, it follows that $F(x) = x$ for all $x \in [0, 1]$. This means that X has the uniform distribution on $(0, 1)$. If $p \neq \frac{1}{2}$, the distribution of X and the uniform distribution are mutually singular, so in particular, X does not have a probability density function with respect to Lebesgue measure.

For an application of some of the ideas in this example, see Bold Play in the game of Red and Black.

Counterexamples

The essential uniqueness of density functions can fail if the underlying positive measure μ is not σ -finite. Here is a trivial counterexample:

Suppose that S is a nonempty set and that $\mathcal{S} = \{S, \emptyset\}$ is the trivial σ -algebra. Define the positive measure μ on (S, \mathcal{S}) by $\mu(\emptyset) = 0$, $\mu(S) = \infty$. Let ν_c denote the measure on (S, \mathcal{S}) with constant density function $c \in \mathbb{R}$ with respect to μ .

1. (S, \mathcal{S}, μ) is not σ -finite.
2. $\nu_c = \mu$ for every $c \in (0, \infty)$.

The Radon-Nikodym theorem can fail if the measure μ is not σ -finite, even if ν is finite. Here are a couple of standard counterexamples:

Suppose that S is an uncountable set and \mathcal{S} is the σ -algebra of *countable and co-countable sets*:

$$\mathcal{S} = \{A \subseteq S : A \text{ is countable or } A^c \text{ is countable}\} \quad (3.13.23)$$

As usual, let $\#$ denote counting measure on \mathcal{S} , and define ν on \mathcal{S} by $\nu(A) = 0$ if A is countable and $\nu(A) = 1$ if A^c is countable. Then

1. $(S, \mathcal{S}, \#)$ is not σ -finite.
2. ν is a finite, positive measure on (S, \mathcal{S}) .
3. ν is absolutely continuous with respect to $\#$.
4. ν does not have a density function with respect to $\#$.

Proof

1. Recall that a countable union of countable sets is countable, and so S cannot be written as such a union.
2. Note that $\nu(\emptyset) = 0$. Suppose that $\{A_i : i \in I\}$ is a countable, disjoint collection of sets in \mathcal{S} . If A_i is countable for every $i \in I$ then $\bigcup_{i \in I} A_i$ is countable. Hence $\nu(\bigcup_{i \in I} A_i) = 0$ and $\nu(A_i) = 0$ for every $i \in I$. Next suppose that A_j^c and A_k^c are countable for distinct $j, k \in I$. Since $A_j \cap A_k = \emptyset$, we have $A_j^c \cup A_k^c = S$. But then S would be countable, which is a contradiction. Hence it is only possible for to have A_j^c countable for a single $j \in I$. In this case, $\nu(A_j) = 1$ and $\nu(A_i) = 0$ for $i \neq j$. But also $(\bigcup_{i \in I} A_i)^c = \bigcap_{i \in I} A_i^c$

is countable, so $\nu(\bigcup_{i \in I} A_i) = 1$. Hence in all cases, $\nu(\bigcup_{i \in I} A_i) = \sum_{i \in I} \nu(A_i)$ so ν is a measure on (S, \mathcal{S}) . It is clearly positive and finite.

3. Recall that any measure is absolutely continuous with respect to counting measure, since $\#(A) = 0$ if and only if $A = \emptyset$.
4. Suppose that ν has density function f with respect to $\#$. Then $0 = \nu\{x\} = \int_{\{x\}} f d\# = f(x)$ for every $x \in S$. But then $\nu(S) = \int_S f d\# = 0$, which is a contradiction.

Let \mathcal{R} denote the standard Borel σ -algebra on \mathbb{R} . Let $\#$ and λ denote counting measure and Lebesgue measure on $(\mathbb{R}, \mathcal{R})$, respectively. Then

1. $(\mathbb{R}, \mathcal{R}, \#)$ is not σ -finite.
2. λ is absolutely continuous with respect to $\#$.
3. λ does not have a density function with respect to $\#$.

Proof

1. \mathbb{R} is uncountable and hence cannot be written as a countable union of finite sets.
2. Since \emptyset is the only null set of $\#$, $\lambda \ll \#$.
3. Suppose that λ has density function f with respect to $\#$. Then

$$0 = \lambda\{x\} = \int_{\{x\}} f d\# = f(x), \quad x \in \mathbb{R} \quad (3.13.24)$$

But then also $\lambda(\mathbb{R}) = \int_{\mathbb{R}} f d\# = 0$, a contradiction.

3.14: Function Spaces

Basic Theory

Our starting point is a positive measure space (S, \mathcal{S}, μ) . That is S is a set, \mathcal{S} is a σ -algebra of subsets of S , and μ is a positive measure on (S, \mathcal{S}) . As usual, the most important special cases are

- *Euclidean space*: S is a Lebesgue measurable subset of \mathbb{R}^n for some $n \in \mathbb{N}_+$, \mathcal{S} is the σ -algebra of Lebesgue measurable subsets of S , and $\mu = \lambda_n$ is n -dimensional Lebesgue measure.
- *Discrete space*: S is a countable set, $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S , and $\mu = \#$ is counting measure.
- *Probability space*: S is the set of outcomes of a random experiment, \mathcal{S} is the σ -algebra of events, and $\mu = \mathbb{P}$ is a probability measure.

In previous sections, we defined the integral of certain measurable functions $f: S \rightarrow \mathbb{R}$ with respect to μ , and we studied properties of the integral. In this section, we will study vector spaces of functions that are defined in terms of certain integrability conditions. These function spaces are of fundamental importance in all areas of analysis, including probability. In particular, the results of this section will reappear in the form of spaces of random variables in our study of expected value.

Definitions and Basic Properties

Consider a statement on the elements of S , for example an equation or an inequality with $x \in S$ as a free variable. (Technically such a statement is a *predicate* on S .) For $A \in \mathcal{S}$, we say that the statement holds *on* A if it is true for every $x \in A$. We say that the statement holds *almost everywhere on* A (with respect to μ) if there exists $B \in \mathcal{S}$ with $B \subseteq A$ such that the statement holds on B and $\mu(A \setminus B) = 0$.

Measurable functions $f, g: S \rightarrow \mathbb{R}$ are *equivalent* if $f = g$ almost everywhere on S , in which case we write $f \equiv g$. The relation \equiv is an equivalence relation on the collection of measurable functions from S to \mathbb{R} . That is, if $f, g, h: S \rightarrow \mathbb{R}$ are measurable then

1. $f \equiv f$, the *reflexive property*.
2. If $f \equiv g$ then $g \equiv f$, the *symmetric property*.
3. If $f \equiv g$ and $g \equiv h$ then $f \equiv h$, the *transitive property*.

Thus, equivalent functions are indistinguishable from the point of view of the measure μ . As with any equivalence relation, \equiv partitions the underlying set (in this case the collection of real-valued measurable functions on S) into equivalence classes of mutually equivalent elements. As we will see, we often view these equivalence classes as the basic objects of study. Our next task is to define measures of the “size” of a function; these will become norms in our spaces.

Suppose that $f: S \rightarrow \mathbb{R}$ is measurable. For $p \in (0, \infty)$ we define

$$\|f\|_p = \left(\int_S |f|^p d\mu \right)^{1/p} \quad (3.14.1)$$

We also define $\|f\|_\infty = \inf \{b \in [0, \infty] : |f| \leq b \text{ almost everywhere on } S\}$.

Since $|f|^p$ is a nonnegative, measurable function for $p \in (0, \infty)$, $\int_S |f|^p d\mu$ exists in $[0, \infty]$, and hence so does $\|f\|_p$. Clearly $\|f\|_\infty$ also exists in $[0, \infty]$ and is known as the *essential supremum* of f . A number $b \in [0, \infty]$ such that $|f| \leq b$ almost everywhere on S is an *essential bound* of f and so, appropriately enough, the essential supremum of f is the infimum of the essential bounds of f . Thus, we have defined $\|f\|_p$ for all $p \in (0, \infty]$. The definition for $p = \infty$ is special, but we will see that it's the appropriate one.

For $p \in (0, \infty]$, let L^p denote the collection of measurable functions $f: S \rightarrow \mathbb{R}$ such that $\|f\|_p < \infty$.

So for $p \in (0, \infty)$, $f \in L^p$ if and only if $|f|^p$ is integrable. The symbol L is in honor of Henri Lebesgue, who first developed the theory. If we want to indicate the dependence on the underlying measure space, we write $L^p(S, \mathcal{S}, \mu)$. Of course, L^1 is simply the

collection of functions that are integrable with respect to μ . Our goal is to study the spaces L^p for $p \in (0, \infty]$. We start with some simple properties.

Suppose that $f : S \rightarrow \mathbb{R}$ is measurable. Then for $p \in (0, \infty]$,

1. $\|f\|_p \geq 0$
2. $\|f\|_p = 0$ if and only if $f = 0$ almost everywhere on S , so that $f \equiv 0$.

Proof

1. This is obvious from the definitions.
2. For $p \in (0, \infty)$, this follows from properties of the integral that we already have. First of course, $\int_S 0^p d\mu = \int_S 0 d\mu = 0$ so $\|0\|_p = 0$. Conversely if $\|f\|_p = 0$ then $\int_S |f|^p d\mu = 0$ and hence $|f|^p = 0$ almost everywhere on S and so $f = 0$ almost everywhere on S . Suppose $p = \infty$. Clearly $\|0\|_\infty = 0$. Conversely suppose that $\|f\|_\infty = 0$. Then for each $n \in \mathbb{N}_+$ there exists $b_n \in [0, \infty)$ with $b_n \rightarrow 0$ as $n \rightarrow \infty$ and $|f| \leq b_n$ almost everywhere on S . Hence $f = 0$ almost everywhere on S .

Suppose that $f : S \rightarrow \mathbb{R}$ is measurable and $c \in \mathbb{R}$. Then $\|cf\|_p = |c| \|f\|_p$ for $p \in (0, \infty]$.

Proof

Again, when $p \in (0, \infty)$, this result follows easily from properties of the integral that we already have:

$$\int_S |cf|^p d\mu = |c|^p \int_S |f|^p d\mu \quad (3.14.2)$$

Taking the p th root of both sides gives the result. For $p = \infty$, the result is trivially true if $c = 0$. For $c \neq 0$, note that $b \in [0, \infty]$ is an essential bound of $|f|$ if and only if $|c|b$ is an essential bound of $|cf|$.

In particular, if $f \in L^p$ and $c \in \mathbb{R}$ then $cf \in L^p$.

Conjugate Indices and Hölder's inequality

Certain pairs of our function spaces turn out to be *dual* or *complementary* to one another in a sense. To understand this, we need the following definition.

Indices $p, q \in (1, \infty)$ are said to be *conjugate* if $1/p + 1/q = 1$. In addition, 1 and ∞ are conjugate indices.

For justification of the last case, note that if $p \in (1, \infty)$, then the index conjugate to p is

$$q = \frac{1}{1 - 1/p} \quad (3.14.3)$$

and $q \uparrow \infty$ as $p \downarrow 1$. Note that $p = q = 2$ are conjugate indices, and this is the only case where the indices are the same. Ultimately, the importance of conjugate indices stems from the following inequality:

If $x, y \in (0, \infty)$ and if $p, q \in (1, \infty)$ are conjugate indices, then

$$xy \leq \frac{1}{p} x^p + \frac{1}{q} y^q \quad (3.14.4)$$

Moreover, equality occurs if and only if $x^p = y^q$.

Proof 1

From properties of the natural logarithm function,

$$\ln(xy) = \ln(x) + \ln(y) = \frac{1}{p} \ln(x^p) + \frac{1}{q} \ln(y^q) \quad (3.14.5)$$

But the natural logarithm function is concave and $1/p + 1/q = 1$ so

$$\ln(xy) = \frac{1}{p} \ln(x^p) + \frac{1}{q} \ln(y^q) \leq \ln\left(\frac{1}{p} x^p + \frac{1}{q} y^q\right) \quad (3.14.6)$$

Taking exponentials we have

$$xy \leq \frac{1}{p}x^p + \frac{1}{q}y^q \quad (3.14.7)$$

Proof 2

Fix $y \in (0, \infty)$ and define $f : (0, \infty) \rightarrow \mathbb{R}$ by

$$f(x) = \frac{1}{p}x^p + \frac{1}{q}y^q - xy, \quad x \in (0, \infty) \quad (3.14.8)$$

Then $f'(x) = x^{p-1} - y$ and $f''(x) = (p-1)x^{p-2}$ for $x \in (0, \infty)$. Hence f has a single critical point at $x = y^{1/(p-1)} = y^{q/p}$ and $f''(x) > 0$ for $x \in (0, \infty)$. It follows that the minimum value of f on $(0, \infty)$ occurs at $y^{q/p}$ and $f(y^{q/p}) = 0$. Hence $f(x) \geq 0$ for $x \in (0, \infty)$ with equality only at $x = y^{q/p}$ (that is, $x^p = y^q$).

our next major result is *Hölder's inequality*, named for Otto Hölder, which clearly indicates the importance of conjugate indices.

Suppose that $f, g : S \rightarrow \mathbb{R}$ are measurable and that p and q are conjugate indices. Then

$$\|fg\|_1 \leq \|f\|_p \|g\|_q \quad (3.14.9)$$

Proof

The result is obvious if $\|f\|_p = \infty$ or $\|g\|_q = \infty$, so suppose that $f \in L^p$ and $g \in L^q$. For our first case, suppose that $p = 1$ and $q = \infty$. Note that $|g| \leq \|g\|_\infty$ almost everywhere on S . Hence

$$\int_S |fg| d\mu = \int_S |f| |g| d\mu \leq \|g\|_\infty \int_S |f| d\mu = \|f\|_1 \|g\|_\infty \quad (3.14.10)$$

For the second case, suppose $p, q \in (1, \infty)$. By part (b) of the [positive property](#), the result holds if $\|f\|_p = 0$ or $\|g\|_q = 0$, so assume that $\|f\|_p > 0$ and $\|g\|_q > 0$. By the additivity of the integral over disjoint domains, we can restrict the integrals to the set $\{x \in S : f(x) \neq 0, g(x) \neq 0\}$, or simply assume that $f \neq 0$ and $g \neq 0$ on S . From the [basic inequality](#),

$$|fg| \leq \frac{1}{p}|f|^p + \frac{1}{q}|g|^q \quad (3.14.11)$$

Suppose first that $\|f\|_p = \|g\|_q = 1$. From the increasing and linearity properties of the integral,

$$\int_S |fg| d\mu \leq \frac{1}{p} \int_S |f|^p d\mu + \frac{1}{q} \int_S |g|^q d\mu = \frac{1}{p} + \frac{1}{q} = 1 \quad (3.14.12)$$

For the general case where $\|f\|_p > 0$ and $\|g\|_q > 0$, let $f_1 = f/\|f\|_p$ and $g_1 = g/\|g\|_q$. Then $\|f_1\|_p = \|g_1\|_q = 1$ so $\|f_1 g_1\|_1 \leq 1$. So by the [scaling property](#),

$$\|f_1 g_1\|_1 = \frac{\|fg\|_1}{\|f\|_p \|g\|_q} \leq 1 \quad (3.14.13)$$

In particular, if $f \in L^p$ and $g \in L^q$ then $fg \in L^1$. The most important special case of Hölder's inequality is when $p = q = 2$, in which case we have the *Cauchy-Schwartz inequality*, named for Augustin Louis Cauchy and Karl Hermann Schwarz:

$$\|fg\|_1 \leq \|f\|_2 \|g\|_2 \quad (3.14.14)$$

Minkowski's Inequality

Our next major result is *Minkowski's inequality*, named for Hermann Minkowski. This inequality will help show that L^p is a vector space and that $\|\cdot\|_p$ is a norm (up to equivalence) when $p \geq 1$.

Suppose that $f, g : S \rightarrow \mathbb{R}$ are measurable and that $p \in [1, \infty]$. Then

$$\|f + g\|_p \leq \|f\|_p + \|g\|_p \quad (3.14.15)$$

Proof

Again, the result is trivial if $\|f\|_p = \infty$ or $\|g\|_p = \infty$, so assume that $f, g \in L^p$. When $p = 1$, the result is the simple triangle inequality for the integral:

$$\|f + g\|_1 = \int_S |f + g| d\mu \leq \int_S (|f| + |g|) d\mu = \int_S |f| d\mu + \int_S |g| d\mu = \|f\|_1 + \|g\|_1 \quad (3.14.16)$$

For the case $p = \infty$, note that if $a \in [0, \infty]$ is an essential bound for f and $b \in [0, \infty]$ is an essential bound for g then $a + b$ is an essential bound for $f + g$. Hence $\|f + g\|_\infty \leq \|f\|_\infty + \|g\|_\infty$. For the last case, suppose that $p \in (1, \infty)$ and let q be the index conjugate to p . Then

$$|f + g|^p = |f + g|^{p-1} |f + g| \leq |f + g|^{p-1} (|f| + |g|) = |f + g|^{p-1} |f| + |f + g|^{p-1} |g| \quad (3.14.17)$$

Integrating over S and using the additive and increasing properties of the integral gives

$$\|f + g\|_p^p \leq \int_S |f + g|^{p-1} |f| d\mu + \int_S |f + g|^{p-1} |g| d\mu \quad (3.14.18)$$

But by Höder's inequality,

$$\int_S |f + g|^{p-1} |f| d\mu \leq \| |f + g|^{p-1} \|_q \|f\|_p, \quad \int_S |f + g|^{p-1} |g| d\mu \leq \| |f + g|^{p-1} \|_q \|g\|_p \quad (3.14.19)$$

Combining this with the previous inequality we have

$$\|f + g\|_p^p \leq \| |f + g|^{p-1} \|_q (\|f\|_p + \|g\|_p) \quad (3.14.20)$$

But $(p-1)q = p$ and $1/q = (p-1)/p$ so

$$\| |f + g|^{p-1} \|_q = \left(\int_S |f + g|^{(p-1)q} d\mu \right)^{1/q} = \left(\int_S |f + g|^p d\mu \right)^{(p-1)/p} = \|f + g\|_p^{p-1} \quad (3.14.21)$$

Hence we have

$$\|f + g\|_p^p \leq \|f + g\|_p^{p-1} (\|f\|_p + \|g\|_p) \quad (3.14.22)$$

and therefore $\|f + g\|_p \leq \|f\|_p + \|g\|_p$.

Vector Spaces

We can now discuss various vector spaces of functions. First, we know from our previous work with measure spaces, that the set \mathcal{V} of all measurable functions $f : S \rightarrow \mathbb{R}$ is a vector space under our standard (pointwise) definitions of sum and scalar multiple. The spaces we are studying in this section are subspaces:

L^p is a subspace of \mathcal{V} for every $p \in [1, \infty]$.

Proof

We just need to show that L^p is closed under addition and scalar multiplication. From the [positive property](#), if $f \in L^p$ and $c \in \mathbb{R}$ then $cf \in L^p$. From [Minkowski's inequality](#), if $f, g \in L^p$ then $f + g \in L^p$.

However, we usually want to *identify* functions that are equal almost everywhere on S (with respect to μ). Recalling the equivalence relation \equiv [defined above](#), here are the definitions:

Let $[f]$ denote the equivalence class of $f \in \mathcal{V}$ under the equivalence relation \equiv , and let $\mathcal{U} = \{[f] : f \in \mathcal{V}\}$. If $f, g \in \mathcal{V}$ and $c \in \mathbb{R}$ we define

1. $[f] + [g] = [f + g]$
2. $c[f] = [cf]$

Then \mathcal{U} is a vector space.

Proof

we know from our previous work that these definitions are consistent in the sense that they do not depend on the particular representatives of the equivalence classes. That is if $f_1 \equiv f$ and $g_1 \equiv g$ then $f_1 + g_1 \equiv f + g$ and $cf_1 \equiv cf$. That \mathcal{U} is a vector space then follows from the fact that \mathcal{V} is a vector space.

Now we can define the Lebesgue vector spaces precisely.

For $p \in [1, \infty]$, let $\mathcal{L}^p = \{[f] : f \in L^p\}$. For $f \in \mathcal{V}$ define $\|[f]\|_p = \|f\|_p$. Then \mathcal{L}^p is a subspace of \mathcal{U} and $\|\cdot\|_p$ is a norm on \mathcal{L}^p . That is, for $f, g \in L^p$ and $c \in \mathbb{R}$

1. $\|f\|_p \geq 0$ and $\|f\|_p = 0$ if and only if $f \equiv 0$, the *positive property*
2. $\|cf\|_p = |c| \|f\|_p$, the *scaling property*
3. $\|f + g\|_p \leq \|f\|_p + \|g\|_p$, the *triangle inequality*

Proof

That \mathcal{L}^p is a subspace of \mathcal{U} follows immediately from the fact that L^p is a subspace of \mathcal{V} . The fact that $\|\cdot\|_p$ is a norm on \mathcal{L}^p also follows from our previous work.

We have stated these results precisely, but on the other hand, we don't want to be overly pedantic. It's more natural and intuitive to simply work with the space \mathcal{V} and the subspaces L^p for $p \in [1, \infty]$, and just remember that functions that are equal almost everywhere on S are regarded as the same vector. This will be our point of view for the rest of this section.

Every norm on a vector space naturally leads to a metric. That is, we measure the distance between vectors as the norm of their difference. Stated in terms of the norm $\|\cdot\|_p$, here are the properties of the metric on L^p .

For $f, g, h \in L^p$,

1. $\|f - g\|_p \geq 0$ and $\|f - g\|_p = 0$ if and only if $f \equiv g$, the *positive property*
2. $\|f - g\|_p = \|g - f\|_p$, the *symmetric property*
3. $\|f - h\|_p \leq \|f - g\|_p + \|g - h\|_p$, the *triangle inequality*

Once we have a metric, we naturally have a criterion for *convergence*.

Suppose that $f_n \in L^p$ for $n \in \mathbb{N}_+$ and $f \in L^p$. Then by definition, $f_n \rightarrow f$ as $n \rightarrow \infty$ in L^p if and only if $\|f_n - f\|_p \rightarrow 0$ as $n \rightarrow \infty$.

Limits are unique, up to equivalence. (That is, limits *are* unique in \mathcal{L}^p .)

Suppose again that $f_n \in L^p$ for $n \in \mathbb{N}_+$. Recall that this sequence is said to be a *Cauchy sequence* if for every $\epsilon > 0$ there exists $N \in \mathbb{N}_+$ such that if $n > N$ and $m > N$ then $\|f_n - f_m\|_p < \epsilon$. Needless to say, the Cauchy criterion is named for our ubiquitous friend Augustin Cauchy. A metric space in which every Cauchy sequence converges (to an element of the space) is said to be *complete*. Intuitively, one expects a Cauchy sequence to converge, so a complete space is literally one that is not missing any elements that should be there. A complete, normed vector space is called a *Banach space*, after the Polish mathematician Stefan Banach. Banach spaces are of fundamental importance in analysis, in large part because of the following result:

L^p is a Banach space for every $p \in [1, \infty]$.

The Space L^2

The norm $\|\cdot\|_2$ is special because it corresponds to an *inner product*.

For $f, g \in L^2$, define

$$\langle f, g \rangle = \int_S fg d\mu \quad (3.14.23)$$

Note that the integral is well-defined by the Cauchy-Schwarz inequality. As with all of our other definitions, this one is consistent with the equivalence relation. That is, if $f \equiv f_1$ and $g \equiv g_1$ then $fg \equiv f_1g_1$ so $\int_S fg d\mu = \int_S f_1g_1 d\mu$ and hence $\langle f, g \rangle = \langle f_1, g_1 \rangle$. Note also that $\langle f, f \rangle = \|f\|_2^2$ for $f \in L^2$, so this definition generates the 2-norm.

L^2 is an inner product space. That is, if $f, g, h \in L^2$ and $c \in \mathbb{R}$ then

1. $\langle f, f \rangle \geq 0$ and $\langle f, f \rangle = 0$ if and only if $f \equiv 0$, the *positive property*
2. $\langle f, g \rangle = \langle g, f \rangle$, the *symmetric property*
3. $\langle cf, g \rangle = c\langle f, g \rangle$, the *scaling property*
4. $\langle f + g, h \rangle = \langle f, h \rangle + \langle g, h \rangle$, the *additive property*

Proof

Part (a) is a restatement of the positive property of the norm $\|\cdot\|_2$. Part (b) is obvious and parts (c) and (d) follow from the linearity of the integral.

From parts (c) and (d), the inner product is linear in the first argument, with the second argument fixed. By the symmetric property (b), it follows that the inner product is also linear in the second argument with the first argument fixed. That is, the inner product is *bi-linear*. A complete inner product space is known as a *Hilbert space*, named for the German mathematician David Hilbert. Thus, the following result follows immediately from the previous two.

L^2 is a Hilbert space.

All inner product spaces lead naturally to the concept of orthogonality; L^2 is no exception.

Functions $f, g \in L^2$ are *orthogonal* if $\langle f, g \rangle = 0$, in which case we write $f \perp g$. Equivalently $f \perp g$ if

$$\int_S fg d\mu = 0 \quad (3.14.24)$$

Of course, all of the basic theorems of general inner product spaces hold in L^2 . For example, the following result is the *Pythagorean theorem*, named of course for Pythagoras.

If $f, g \in L^2$ and $f \perp g$ then $\|f + g\|_2^2 = \|f\|_2^2 + \|g\|_2^2$.

Proof

The proof just uses basic properties of inner product in (17). No special properties of L^2 are used. If $f, g \in L^2$ and $f \perp g$ then

$$\|f + g\|^2 = \langle f + g, f + g \rangle = \langle f, f \rangle + 2\langle f, g \rangle + \langle g, g \rangle = \|f\|^2 + \|g\|^2 \quad (3.14.25)$$

Examples and Special Cases

Discrete Spaces

Recall again that the measure space $(S, \mathcal{S}, \#)$ is *discrete* if S is countable, $\mathcal{S} = \mathcal{P}(S)$ is the σ -algebra of all subsets of S , and of course, $\#$ is counting measure. In this case, recall that integrals are sums. The exposition will look more familiar if we use the notation of sequences rather than functions. Thus, let $x : S \rightarrow \mathbb{R}$, and denote the value of x at $i \in S$ by x_i rather than $x(i)$. For $p \in [1, \infty)$, the p -norm is

$$\|x\|_p = \left(\sum_{i \in S} |x_i|^p \right)^{1/p} \quad (3.14.26)$$

On the other hand, $\|x\|_\infty = \sup\{x_i : i \in S\}$. The only null set for $\#$ is \emptyset , so the equivalence relation \equiv is simply equality, and so the spaces L^p and \mathcal{L}^p are the same. For $p \in [1, \infty)$, $x \in L^p$ if and only if

$$\sum_{i \in S} |x_i|^p < \infty \quad (3.14.27)$$

When $p \in \mathbb{N}_+$ (as is often the case), this condition means that $\sum_{i \in S} x_i^p$ is absolutely convergent. On the other hand, $x \in L^\infty$ if and only if x is bounded. When $S = \mathbb{N}_+$, the space L^p is often denoted ℓ^p . The inner product on L^2 is

$$\langle x, y \rangle = \sum_{i \in S} x_i y_i, \quad x, y \in L^2 \quad (3.14.28)$$

When $S = \{1, 2, \dots, n\}$, L^2 is simply the vector space \mathbb{R}^n with the usual addition, scalar multiplication, inner product, and norm that we study in elementary linear algebra. Orthogonal vectors are perpendicular in the usual sense.

Probability Spaces

Suppose that $(S, \mathcal{S}, \mathbb{P})$ is a probability space, so that S is the set of outcomes of a random experiment, \mathcal{S} is the σ -algebra of events, and \mathbb{P} is a probability measure on the sample space (S, \mathcal{S}) . Of course, a measurable function $X : S \rightarrow \mathbb{R}$ is simply a real-valued random variable. For $p \in [1, \infty)$, the integral $\int_S |x|^p d\mathbb{P}$ is the *expected value* of $|X|^p$, and is denoted $\mathbb{E}(|X|^p)$. Thus in this case, L^p is the collection of real-valued random variables X with $\mathbb{E}(|X|^p) < \infty$. We will study these spaces in more detail in the chapter on expected value.

CHAPTER OVERVIEW

4: Expected Value

Expected value is one of the fundamental concepts in probability, in a sense more general than probability itself. The expected value of a real-valued random variable gives a measure of the center of the distribution of the variable. More importantly, by taking the expected value of various functions of a general random variable, we can measure many interesting features of its distribution, including spread, skewness, kurtosis, and correlation. Generating functions are certain types of expected value that completely determine the distribution of the variable. Conditional expected value, which incorporates known information in the computation, is one of the fundamental concepts in probability.

In the advanced topics, we define expected value as an integral with respect to the underlying probability measure. We also revisit conditional expected value from a measure-theoretic point of view. We study vector spaces of random variables with certain expected values as the norms of the spaces, which in turn leads to modes of convergence for random variables.

4.1: Definitions and Basic Properties

Expected value is one of the most important concepts in probability. The expected value of a real-valued random variable gives the center of the distribution of the variable, in a special sense. Additionally, by computing expected values of various real transformations of a general random variable, we can extract a number of interesting characteristics of the distribution of the variable, including measures of spread, symmetry, and correlation. In a sense, expected value is a more general concept than probability itself.

Basic Concepts

Definitions

As usual, we start with a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} the collection of events and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) . In the following definitions, we assume that X is a random variable for the experiment, taking values in $S \subseteq \mathbb{R}$.

If X has a discrete distribution with probability density function f (so that S is countable), then the *expected value* of X is defined as follows (assuming that the sum is well defined):

$$\mathbb{E}(X) = \sum_{x \in S} x f(x) \quad (4.1.1)$$

The sum defining the expected value makes sense if either the sum over the positive $x \in S$ is finite or the sum over the negative $x \in S$ is finite (or both). This ensures that the entire sum exists (as an extended real number) and does not depend on the order of the terms. So as we will see, it's possible for $\mathbb{E}(X)$ to be a real number or ∞ or $-\infty$ or to simply not exist. Of course, if S is finite the expected value always exists as a real number.

If X has a continuous distribution with probability density function f (and so S is typically an interval or a union of disjoint intervals), then the *expected value* of X is defined as follows (assuming that the integral is well defined):

$$\mathbb{E}(X) = \int_S x f(x) dx \quad (4.1.2)$$

The probability density functions in basic applied probability that describe continuous distributions are piecewise continuous. So the integral above makes sense if the integral over positive $x \in S$ is finite or the integral over negative $x \in S$ is finite (or both). This ensures that the entire integral exists (as an extended real number). So as in the discrete case, it's possible for $\mathbb{E}(X)$ to exist as a real number or as ∞ or as $-\infty$ or to not exist at all. As you might guess, the definition for a mixed distribution is a combination of the definitions for the discrete and continuous cases.

If X has a mixed distribution, with partial discrete density g on D and partial continuous density h on C , where D and C are disjoint, D is countable, C is typically an interval, and $S = D \cup C$. The expected value of X is defined as follows (assuming that the expression on the right is well defined):

$$\mathbb{E}(X) = \sum_{x \in D} x g(x) + \int_C x h(x) dx \quad (4.1.3)$$

For the expected value above to make sense, the sum must be well defined, as in the discrete case, the integral must be well defined, as in the continuous case, and we must avoid the dreaded indeterminate form $\infty - \infty$. In the next section on additional properties, we will see that the various definitions given here can be unified into a single definition that works regardless of the type of distribution of X . An even more general definition is given in the advanced section on expected value as an integral.

Interpretation

The expected value of X is also called the *mean* of the distribution of X and is frequently denoted μ . The mean is the center of the probability distribution of X in a special sense. Indeed, if we think of the distribution as a mass distribution (with total mass 1), then the mean is the *center of mass* as defined in physics. The two pictures below show discrete and continuous probability density functions; in each case the mean μ is the center of mass, the balance point.

Figure 4.1.1: The mean μ as the center of mass of a discrete distribution.

Figure 4.1.2: The mean μ as the center of mass of a continuous distribution.

Recall the other measures of the center of a distribution that we have studied:

- A mode is any $x \in S$ that maximizes f .
- A median is any $x \in \mathbb{R}$ that satisfies $\mathbb{P}(X < x) \leq \frac{1}{2}$ and $\mathbb{P}(X \leq x) \geq \frac{1}{2}$.

To understand expected value in a probabilistic way, suppose that we create a new, compound experiment by repeating the basic experiment over and over again. This gives a sequence of independent random variables (X_1, X_2, \dots) , each with the same distribution as X . In statistical terms, we are sampling from the distribution of X . The average value, or *sample mean*, after n runs is

$$M_n = \frac{1}{n} \sum_{i=1}^n X_i \quad (4.1.4)$$

Note that M_n is a random variable in the compound experiment. The important fact is that the *average value* M_n converges to the *expected value* $\mathbb{E}(X)$ as $n \rightarrow \infty$. The precise statement of this is the law of large numbers, one of the fundamental theorems of probability. You will see the law of large numbers at work in many of the simulation exercises given below.

Extensions

If $a \in \mathbb{R}$ and $n \in \mathbb{N}$, the *moment of X about a of order n* is defined to be

$$\mathbb{E}[(X - a)^n] \quad (4.1.5)$$

(assuming of course that this expected value exists).

The moments about 0 are simply referred to as *moments* (or sometimes *raw moments*). The moments about μ are the *central moments*. The second central moment is particularly important, and is studied in detail in the section on variance. In some cases, if we know *all* of the moments of X , we can determine the entire distribution of X . This idea is explored in the section on generating functions.

The expected value of a random variable X is based, of course, on the probability measure \mathbb{P} for the experiment. This probability measure could be a conditional probability measure, conditioned on a given event $A \in \mathcal{F}$ for the experiment (with $\mathbb{P}(A) > 0$). The usual notation is $\mathbb{E}(X | A)$, and this expected value is computed by the definitions given above, except that the conditional probability density function $x \mapsto f(x | A)$ replaces the ordinary probability density function f . It is very important to realize that, except for notation, no new concepts are involved. All results that we obtain for expected value in general have analogues for these conditional expected values. On the other hand, we will study a more general notion of conditional expected value in a later section.

Basic Properties

The purpose of this subsection is to study some of the essential properties of expected value. Unless otherwise noted, we will assume that the indicated expected values exist, and that the various sets and functions that we use are measurable. We start with two simple but still essential results.

Simple Variables

First, recall that a constant $c \in \mathbb{R}$ can be thought of as a random variable (on any probability space) that takes only the value c with probability 1. The corresponding distribution is sometimes called *point mass* at c .

If c is a constant random variable, then $\mathbb{E}(c) = c$.

Proof

As a random variable, c has a discrete distribution, so $\mathbb{E}(c) = c \cdot 1 = c$.

Next recall that an indicator variable is a random variable that takes only the values 0 and 1.

If X is an indicator variable then $\mathbb{E}(X) = \mathbb{P}(X = 1)$.

Proof

X is discrete so by definition, $\mathbb{E}(X) = 1 \cdot \mathbb{P}(X = 1) + 0 \cdot \mathbb{P}(X = 0) = \mathbb{P}(X = 1)$.

In particular, if $\mathbf{1}_A$ is the indicator variable of an event A , then $\mathbb{E}(\mathbf{1}_A) = \mathbb{P}(A)$, so in a sense, expected value subsumes probability. For a book that takes expected value, rather than probability, as the fundamental starting concept, see the book [Probability via Expectation](#), by Peter Whittle.

Change of Variables Theorem

The expected value of a real-valued random variable gives the center of the distribution of the variable. This idea is much more powerful than might first appear. By finding expected values of various *functions* of a general random variable, we can measure many interesting features of its distribution.

Thus, suppose that X is a random variable taking values in a general set S , and suppose that r is a function from S into \mathbb{R} . Then $r(X)$ is a real-valued random variable, and so it makes sense to compute $\mathbb{E}[r(X)]$ (assuming as usual that this expected value exists). However, to compute this expected value from the definition would require that we know the probability density function of the transformed variable $r(X)$ (a difficult problem, in general). Fortunately, there is a much better way, given by the *change of variables theorem* for expected value. This theorem is sometimes referred to as the *law of the unconscious statistician*, presumably because it is so basic and natural that it is often used without the realization that it is a theorem, and not a definition.

If X has a discrete distribution on a countable set S with probability density function f , then

$$\mathbb{E}[r(X)] = \sum_{x \in S} r(x)f(x) \quad (4.1.6)$$

Proof

Figure 4.1.3: The change of variables theorem when X has a discrete distribution.

The next result is the change of variables theorem when X has a continuous distribution. We will prove the continuous version in stages, first when r has discrete range below and then in the next section in full generality. Even though the complete proof is delayed, however, we will use the change of variables theorem in the proofs of many of the other properties of expected value.

Suppose that X has a continuous distribution on $S \subseteq \mathbb{R}^n$ with probability density function f , and that $r : S \rightarrow \mathbb{R}$. Then

$$\mathbb{E}[r(X)] = \int_S r(x)f(x) dx \quad (4.1.7)$$

Proof when r has discrete range

Figure 4.1.4: The change of variables theorem when X has a continuous distribution and r has countable range.

The results below gives basic properties of expected value. These properties are true in general, but we will restrict the proofs primarily to the continuous case. The proofs for the discrete case are analogous, with sums replacing integrals. The change of variables theorem is the main tool we will need. In these theorems X and Y are real-valued random variables for an experiment (that is, defined on an underlying probability space) and c is a constant. As usual, we assume that the indicated expected values exist. Be sure to try the proofs yourself before reading the ones in the text.

Linearity

Our first property is the *additive property*.

$$\mathbb{E}(X + Y) = \mathbb{E}(X) + \mathbb{E}(Y)$$

Proof

We apply the [change of variables theorem](#) with the function $r(x, y) = x + y$. Suppose that (X, Y) has a continuous distribution with PDF f , and that X takes values in $S \subseteq \mathbb{R}$ and Y takes values in $T \subseteq \mathbb{R}$. Recall that X has PDF g given by $g(x) = \int_T f(x, y) dy$ for $x \in S$ and Y has PDF h given by $h(y) = \int_S f(x, y) dx$ for $y \in T$. Thus

$$\mathbb{E}(X + Y) = \int_{S \times T} (x + y) f(x, y) d(x, y) = \int_{S \times T} x f(x, y) d(x, y) + \int_{S \times T} y f(x, y) d(x, y) \quad (4.1.8)$$

$$= \int_S x \left(\int_T f(x, y) dy \right) dx + \int_T y \left(\int_S f(x, y) dx \right) dy = \int_S x g(x) dx + \int_T y h(y) dy = \mathbb{E}(X) + \mathbb{E}(Y) \quad (4.1.9)$$

Writing the double integrals as iterated integrals is a special case of Fubini's theorem. The proof in the discrete case is the same, with sums replacing integrals.

Our next property is the *scaling property*.

$$\mathbb{E}(cX) = c \mathbb{E}(X)$$

Proof

We apply the [change of variables formula](#) with the function $r(x) = cx$. Suppose that X has a continuous distribution on $S \subseteq \mathbb{R}$ with PDF f . Then

$$\mathbb{E}(cX) = \int_S c x f(x) dx = c \int_S x f(x) dx = c \mathbb{E}(X) \quad (4.1.10)$$

Again, the proof in the discrete case is the same, with sums replacing integrals.

Here is the linearity of expected value in full generality. It's a simple corollary of the previous two results.

Suppose that (X_1, X_2, \dots) is a sequence of real-valued random variables defined on the underlying probability space and that (a_1, a_2, \dots, a_n) is a sequence of constants. Then

$$\mathbb{E} \left(\sum_{i=1}^n a_i X_i \right) = \sum_{i=1}^n a_i \mathbb{E}(X_i) \quad (4.1.11)$$

Thus, expected value is a *linear operation* on the collection of real-valued random variables for the experiment. The linearity of expected value is so basic that it is important to understand this property on an intuitive level. Indeed, it is implied by the interpretation of expected value given in the law of large numbers.

Suppose that (X_1, X_2, \dots, X_n) is a sequence of real-valued random variables with common mean μ .

1. Let $Y = \sum_{i=1}^n X_i$, the sum of the variables. Then $\mathbb{E}(Y) = n\mu$.
2. Let $M = \frac{1}{n} \sum_{i=1}^n X_i$, the average of the variables. Then $\mathbb{E}(M) = \mu$.

Proof

1. By the [additive property](#),

$$\mathbb{E}(Y) = \mathbb{E} \left(\sum_{i=1}^n X_i \right) = \sum_{i=1}^n \mathbb{E}(X_i) = \sum_{i=1}^n \mu = n\mu \quad (4.1.12)$$

2. Note that $M = Y/n$. Hence from the [scaling property](#) and part (a), $\mathbb{E}(M) = \mathbb{E}(Y)/n = \mu$.

If the random variables in the previous result are also independent and identically distributed, then in statistical terms, the sequence is a *random sample* of size n from the common distribution, and M is the *sample mean*.

In several important cases, a random variable from a special distribution can be decomposed into a sum of simpler random variables, and then part (a) of the [last theorem](#) can be used to compute the expected value.

Inequalities

The following exercises give some basic inequalities for expected value. The first, known as the *positive property* is the most obvious, but is also the main tool for proving the others.

Suppose that $\mathbb{P}(X \geq 0) = 1$. Then

1. $\mathbb{E}(X) \geq 0$
2. If $\mathbb{P}(X > 0) > 0$ then $\mathbb{E}(X) > 0$.

Proof

1. This result follows from the definition, since we can take the set of values S of X to be a subset of $[0, \infty)$.
2. Suppose that $\mathbb{P}(X > 0) > 0$ (in addition to $\mathbb{P}(X \geq 0) = 1$). By the continuity theorem for increasing events, there exists $\epsilon > 0$ such that $\mathbb{P}(X \geq \epsilon) > 0$. Therefore $X - \epsilon \mathbf{1}_{(X \geq \epsilon)} \geq 0$ (with probability 1). By part (a), linearity, and Theorem 2, $\mathbb{E}(X) - \epsilon \mathbb{P}(X \geq \epsilon) > 0$ so $\mathbb{E}(X) \geq \epsilon \mathbb{P}(X \geq \epsilon) > 0$.

Next is the *increasing property*, perhaps the most important property of expected value, after linearity.

Suppose that $\mathbb{P}(X \leq Y) = 1$. Then

1. $\mathbb{E}(X) \leq \mathbb{E}(Y)$
2. If $\mathbb{P}(X < Y) > 0$ then $\mathbb{E}(X) < \mathbb{E}(Y)$.

Proof

1. The assumption is equivalent to $\mathbb{P}(Y - X \geq 0) = 1$. Thus $\mathbb{E}(Y - X) \geq 0$ by part (a) of the [positive property](#). But then $\mathbb{E}(Y) - \mathbb{E}(X) \geq 0$ by the linearity of expected value.
2. Similarly, this result follows from part (b) of the [positive property](#).

Absolute value inequalities:

1. $|\mathbb{E}(X)| \leq \mathbb{E}(|X|)$
2. If $\mathbb{P}(X > 0) > 0$ and $\mathbb{P}(X < 0) > 0$ then $|\mathbb{E}(X)| < \mathbb{E}(|X|)$.

Proof

1. Note that $-|X| \leq X \leq |X|$ (with probability 1) so by part (a) of the [increasing property](#), $\mathbb{E}(-|X|) \leq \mathbb{E}(X) \leq \mathbb{E}(|X|)$. By linearity, $-\mathbb{E}(|X|) \leq \mathbb{E}(X) \leq \mathbb{E}(|X|)$ which implies $|\mathbb{E}(X)| \leq \mathbb{E}(|X|)$.
2. If $\mathbb{P}(X > 0) > 0$ then $\mathbb{P}(-|X| < X) > 0$, and if $\mathbb{P}(X < 0) > 0$ then $\mathbb{P}(X < |X|) > 0$. Hence by part (b) of the [increasing property](#), $-\mathbb{E}(|X|) < \mathbb{E}(X) < \mathbb{E}(|X|)$ and therefore $|\mathbb{E}(X)| < \mathbb{E}(|X|)$.

Only in [Lake Wobegone](#) are all of the children above average:

If $\mathbb{P}[X \neq \mathbb{E}(X)] > 0$ then

1. $\mathbb{P}[X > \mathbb{E}(X)] > 0$
2. $\mathbb{P}[X < \mathbb{E}(X)] > 0$

Proof

1. We prove the contrapositive. Thus suppose that $\mathbb{P}[X > \mathbb{E}(X)] = 0$ so that $\mathbb{P}[X \leq \mathbb{E}(X)] = 1$. If $\mathbb{P}[X < \mathbb{E}(X)] > 0$ then by the [increasing property](#) we have $\mathbb{E}(X) < \mathbb{E}(X)$, a contradiction. Thus $\mathbb{P}[X = \mathbb{E}(X)] = 1$.
2. Similarly, if $\mathbb{P}[X < \mathbb{E}(X)] = 0$ then $\mathbb{P}[X = \mathbb{E}(X)] = 1$.

Thus, if X is not a constant (with probability 1), then X must take values greater than its mean with positive probability and values less than its mean with positive probability.

Symmetry

Again, suppose that X is a random variable taking values in \mathbb{R} . The distribution of X is *symmetric* about $a \in \mathbb{R}$ if the distribution of $a - X$ is the same as the distribution of $X - a$.

Suppose that the distribution of X is symmetric about $a \in \mathbb{R}$. If $\mathbb{E}(X)$ exists, then $\mathbb{E}(X) = a$.

Proof

By assumption, the distribution of $X - a$ is the same as the distribution of $a - X$. Since $\mathbb{E}(X)$ exists we have $\mathbb{E}(a - X) = \mathbb{E}(X - a)$ so by linearity $a - \mathbb{E}(X) = \mathbb{E}(X) - a$. Equivalently $2\mathbb{E}(X) = 2a$.

The previous result applies if X has a continuous distribution on \mathbb{R} with a probability density f that is symmetric about a ; that is, $f(a + x) = f(a - x)$ for $x \in \mathbb{R}$.

Independence

If X and Y are independent real-valued random variables then $\mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y)$.

Proof

Suppose that X has a continuous distribution on $S \subseteq \mathbb{R}$ with PDF g and that Y has a continuous distribution on $T \subseteq \mathbb{R}$ with PDF h . Then (X, Y) has PDF $f(x, y) = g(x)h(y)$ on $S \times T$. We apply the [change of variables theorem](#) with the function $r(x, y) = xy$.

$$\mathbb{E}(XY) = \int_{S \times T} xyf(x, y) d(x, y) = \int_{S \times T} xyg(x)h(y) d(x, y) = \int_S xg(x) dx \int_T yh(y) dy = \mathbb{E}(X)\mathbb{E}(Y) \quad (4.1.13)$$

The proof in the discrete case is similar with sums replacing integrals.

It follows from the last result that independent random variables are uncorrelated (a concept that we will study in a later section). Moreover, this result is more powerful than might first appear. Suppose that X and Y are independent random variables taking values in general spaces S and T respectively, and that $u : S \rightarrow \mathbb{R}$ and $v : T \rightarrow \mathbb{R}$. Then $u(X)$ and $v(Y)$ are independent, real-valued random variables and hence

$$\mathbb{E}[u(X)v(Y)] = \mathbb{E}[u(X)]\mathbb{E}[v(Y)] \quad (4.1.14)$$

Examples and Applications

As always, be sure to try the proofs and computations yourself before reading the proof and answers in the text.

Uniform Distributions

Discrete uniform distributions are widely used in combinatorial probability, and model a point chosen *at random* from a finite set.

Suppose that X has the discrete uniform distribution on a finite set $S \subseteq \mathbb{R}$.

1. $\mathbb{E}(X)$ is the arithmetic average of the numbers in S .
2. If the points in S are evenly spaced with endpoints a, b , then $\mathbb{E}(X) = \frac{a+b}{2}$, the average of the endpoints.

Proof

1. Let $n = \#(S)$, the number of points in S . Then X has PDF $f(x) = 1/n$ for $x \in S$ so

$$\mathbb{E}(X) = \sum_{x \in S} x \frac{1}{n} = \frac{1}{n} \sum_{x \in S} x \quad (4.1.15)$$

2. Suppose that $S = \{a, a + h, a + 2h, \dots, a + (n - 1)h\}$ and let $b = a + (n - 1)h$, the right endpoint. As in (a), S has n points so using (a) and the formula for the sum of the first $n - 1$ positive integers, we have

$$\mathbb{E}(X) = \frac{1}{n} \sum_{i=0}^{n-1} (a + ih) = \frac{1}{n} \left(na + h \frac{(n-1)n}{2} \right) = a + \frac{(n-1)h}{2} = \frac{a+b}{2} \quad (4.1.16)$$

The previous results are easy to see if we think of $\mathbb{E}(X)$ as the center of mass, since the discrete uniform distribution corresponds to a finite set of points with equal mass.

Open the special distribution simulator, and select the discrete uniform distribution. This is the uniform distribution on n points, starting at a , evenly spaced at distance h . Vary the parameters and note the location of the mean in relation to the probability density function. For selected values of the parameters, run the simulation 1000 times and compare the empirical mean to the distribution mean.

Next, recall that the continuous uniform distribution on a bounded interval corresponds to selecting a point *at random* from the interval. Continuous uniform distributions arise in geometric probability and a variety of other applied problems.

Suppose that X has the continuous uniform distribution on an interval $[a, b]$, where $a, b \in \mathbb{R}$ and $a < b$.

1. $\mathbb{E}(X) = \frac{a+b}{2}$, the midpoint of the interval.
2. $\mathbb{E}(X^n) = \frac{1}{n+1} (a^n + a^{n-1}b + \dots + ab^{n-1} + b^n)$ for $n \in \mathbb{N}$.

Proof

1. Recall that X has PDF $f(x) = \frac{1}{b-a}$. Hence

$$\mathbb{E}(X) = \int_a^b x \frac{1}{b-a} dx = \frac{1}{b-a} \frac{b^2 - a^2}{2} = \frac{a+b}{2} \quad (4.1.17)$$

2. By the [change of variables formula](#),

$$\mathbb{E}(X^n) = \int_a^b \frac{1}{b-a} x^n dx = \frac{b^{n+1} - a^{n+1}}{(n+1)(b-a)} = \frac{1}{n+1} (a^n + a^{n-1}b + \dots + ab^{n-1} + b^n) \quad (4.1.18)$$

Part (a) is easy to see if we think of the mean as the center of mass, since the uniform distribution corresponds to a uniform distribution of mass on the interval.

Open the special distribution simulator, and select the continuous uniform distribution. This is the uniform distribution the interval $[a, a+w]$. Vary the parameters and note the location of the mean in relation to the probability density function. For selected values of the parameters, run the simulation 1000 times and compare the empirical mean to the distribution mean.

Next, the *average value* of a function on an interval, as defined in calculus, has a nice interpretation in terms of the uniform distribution.

Suppose that X is uniformly distributed on the interval $[a, b]$, and that g is an integrable function from $[a, b]$ into \mathbb{R} . Then $\mathbb{E}[g(X)]$ is the average value of g on $[a, b]$:

$$\mathbb{E}[g(X)] = \frac{1}{b-a} \int_a^b g(x) dx \quad (4.1.19)$$

Proof

This result follows immediately from the change of variables theorem, since X has PDF $f(x) = 1/(b-a)$ for $a \leq x \leq b$.

Find the average value of the following functions on the given intervals:

1. $f(x) = x$ on $[2, 4]$
2. $g(x) = x^2$ on $[0, 1]$
3. $h(x) = \sin(x)$ on $[0, \pi]$.

Answer

1. 3
2. $\frac{1}{3}$
3. $\frac{2}{\pi}$

The next exercise illustrates the value of the change of variables theorem in computing expected values.

Suppose that X is uniformly distributed on $[-1, 3]$.

1. Give the probability density function of X .
2. Find the probability density function of X^2 .
3. Find $\mathbb{E}(X^2)$ using the probability density function in (b).
4. Find $\mathbb{E}(X^2)$ using the [change of variables theorem](#).

Answer

1. $f(x) = \frac{1}{4}$ for $-1 \leq x \leq 3$
2. $g(y) = \begin{cases} \frac{1}{4}y^{-1/2}, & 0 < y < 1 \\ \frac{1}{8}y^{-1/2}, & 1 < y < 9 \end{cases}$

$$3. \int_0^9 yg(y) dy = \frac{7}{3}$$

$$4. \int_{-1}^3 x^2 f(x) dx = \frac{7}{3}$$

The discrete uniform distribution and the continuous uniform distribution are studied in more detail in the chapter on Special Distributions.

Dice

Recall that a *standard die* is a six-sided die. A *fair die* is one in which the faces are equally likely. An *ace-six flat die* is a standard die in which faces 1 and 6 have probability $\frac{1}{4}$ each, and faces 2, 3, 4, and 5 have probability $\frac{1}{8}$ each.

Two standard, fair dice are thrown, and the scores (X_1, X_2) recorded. Find the expected value of each of the following variables.

1. $Y = X_1 + X_2$, the sum of the scores.
2. $M = \frac{1}{2}(X_1 + X_2)$, the average of the scores.
3. $Z = X_1 X_2$, the product of the scores.
4. $U = \min\{X_1, X_2\}$, the minimum score
5. $V = \max\{X_1, X_2\}$, the maximum score.

Answer

1. 7
2. $\frac{7}{2}$
3. $\frac{49}{4}$
4. $\frac{101}{36}$
5. $\frac{19}{4}$

In the dice experiment, select two fair die. Note the shape of the probability density function and the location of the mean for the sum, minimum, and maximum variables. Run the experiment 1000 times and compare the sample mean and the distribution mean for each of these variables.

Two standard, ace-six flat dice are thrown, and the scores (X_1, X_2) recorded. Find the expected value of each of the following variables.

1. $Y = X_1 + X_2$, the sum of the scores.
2. $M = \frac{1}{2}(X_1 + X_2)$, the average of the scores.
3. $Z = X_1 X_2$, the product of the scores.
4. $U = \min\{X_1, X_2\}$, the minimum score
5. $V = \max\{X_1, X_2\}$, the maximum score.

Answer

1. 7
2. $\frac{7}{2}$
3. $\frac{49}{4}$
4. $\frac{77}{32}$
5. $\frac{147}{32}$

In the dice experiment, select two ace-six flat die. Note the shape of the probability density function and the location of the mean for the sum, minimum, and maximum variables. Run the experiment 1000 times and compare the sample mean and the distribution mean for each of these variables.

Bernoulli Trials

Recall that a *Bernoulli trials process* is a sequence $\mathbf{X} = (X_1, X_2, \dots)$ of independent, identically distributed indicator random variables. In the usual language of reliability, X_i denotes the outcome of trial i , where 1 denotes success and 0 denotes failure. The probability of success $p = \mathbb{P}(X_i = 1) \in [0, 1]$ is the basic parameter of the process. The process is named for Jacob Bernoulli. A separate chapter on the Bernoulli Trials explores this process in detail.

For $n \in \mathbb{N}_+$, the number of successes in the first n trials is $Y = \sum_{i=1}^n X_i$. Recall that this random variable has the binomial distribution with parameters n and p , and has probability density function f given by

$$f(y) = \binom{n}{y} p^y (1-p)^{n-y}, \quad y \in \{0, 1, \dots, n\} \quad (4.1.20)$$

If Y has the binomial distribution with parameters n and p then $\mathbb{E}(Y) = np$

Proof from the definition

The critical tools that we need involve binomial coefficients: the identity $y \binom{n}{y} = n \binom{n-1}{y-1}$ for $y, n \in \mathbb{N}_+$, and the binomial theorem:

$$\mathbb{E}(Y) = \sum_{y=0}^n y \binom{n}{y} p^y (1-p)^{n-y} = \sum_{y=1}^n n \binom{n-1}{y-1} p^y (1-p)^{n-y} \quad (4.1.21)$$

$$= np \sum_{y=1}^{n-1} \binom{n-1}{y-1} p^{y-1} (1-p)^{(n-1)-(y-1)} = np [p + (1-p)]^{n-1} = np \quad (4.1.22)$$

Proof using the additive property

Since $Y = \sum_{i=1}^n X_i$, the result follows immediately from the [expected value of an indicator variable](#) and the [additive property](#), since $\mathbb{E}(X_i) = p$ for each $i \in \mathbb{N}_+$.

Note the superiority of the second proof to the first. The result also makes intuitive sense: in n trials with success probability p , we expect np successes.

In the binomial coin experiment, vary n and p and note the shape of the probability density function and the location of the mean. For selected values of n and p , run the experiment 1000 times and compare the sample mean to the distribution mean.

Suppose that $p \in (0, 1]$, and let N denote the trial number of the first success. This random variable has the geometric distribution on \mathbb{N}_+ with parameter p , and has probability density function g given by

$$g(n) = p(1-p)^{n-1}, \quad n \in \mathbb{N}_+ \quad (4.1.23)$$

If N has the geometric distribution on \mathbb{N}_+ with parameter $p \in (0, 1]$ then $\mathbb{E}(N) = 1/p$.

Proof

The key is the formula for the derivative of a geometric series:

$$\mathbb{E}(N) = \sum_{n=1}^{\infty} np(1-p)^{n-1} = -p \frac{d}{dp} \sum_{n=0}^{\infty} (1-p)^n = -p \frac{d}{dp} \frac{1}{p} = p \frac{1}{p^2} = \frac{1}{p} \quad (4.1.24)$$

Again, the result makes intuitive sense. Since p is the probability of success, we expect a success to occur after $1/p$ trials.

In the negative binomial experiment, select $k = 1$ to get the geometric distribution. Vary p and note the shape of the probability density function and the location of the mean. For selected values of p , run the experiment 1000 times and compare the sample mean to the distribution mean.

The Hypergeometric Distribution

Suppose that a population consists of m objects; r of the objects are type 1 and $m-r$ are type 0. A sample of n objects is chosen at random, without replacement. The parameters $m, r, n \in \mathbb{N}$ with $r \leq m$ and $n \leq m$. Let X_i denote the type of the i th object selected. Recall that $\mathbf{X} = (X_1, X_2, \dots, X_n)$ is a sequence of identically distributed (but *not* independent) indicator random variable with $\mathbb{P}(X_i = 1) = r/m$ for each $i \in \{1, 2, \dots, n\}$.

Let Y denote the number of type 1 objects in the sample, so that $Y = \sum_{i=1}^n X_i$. Recall that Y has the hypergeometric distribution, which has probability density function f given by

$$f(y) = \frac{\binom{r}{y} \binom{m-r}{n-y}}{\binom{m}{n}}, \quad y \in \{0, 1, \dots, n\} \quad (4.1.25)$$

If Y has the hypergeometric distribution with parameters m, n , and r then $\mathbb{E}(Y) = n \frac{r}{m}$.

Proof from the definition

Using the hypergeometric PDF,

$$\mathbb{E}(Y) = \sum_{y=0}^n y \frac{\binom{r}{y} \binom{m-r}{n-y}}{\binom{m}{n}} \quad (4.1.26)$$

Note that the $y = 0$ term is 0. For the other terms, we can use the identity $y \binom{r}{y} = r \binom{r-1}{y-1}$ to get

$$\mathbb{E}(Y) = \frac{r}{\binom{m}{n}} \sum_{y=1}^n \binom{r-1}{y-1} \binom{m-r}{n-y} \quad (4.1.27)$$

But substituting $k = y - 1$ and using another fundamental identity,

$$\sum_{y=1}^n \binom{r-1}{y-1} \binom{m-r}{n-y} = \sum_{k=0}^{n-1} \binom{r-1}{k} \binom{m-r}{n-1-k} = \binom{m-1}{n-1} \quad (4.1.28)$$

So substituting and doing a bit of algebra gives $\mathbb{E}(Y) = n \frac{r}{m}$.

Proof using the additive property

A much better proof uses the [additive property](#) and the representation of Y as a sum of indicator variables. The result follows immediately since $\mathbb{E}(X_i) = r/m$ for each $i \in \{1, 2, \dots, n\}$.

In the ball and urn experiment, vary n , r , and m and note the shape of the probability density function and the location of the mean. For selected values of the parameters, run the experiment 1000 times and compare the sample mean to the distribution mean.

Note that if we select the objects *with replacement*, then \mathbf{X} would be a sequence of Bernoulli trials, and hence Y would have the binomial distribution with parameters n and $p = \frac{r}{m}$. Thus, the mean would still be $\mathbb{E}(Y) = n \frac{r}{m}$.

The Poisson Distribution

Recall that the *Poisson distribution* has probability density function f given by

$$f(n) = e^{-a} \frac{a^n}{n!}, \quad n \in \mathbb{N} \quad (4.1.29)$$

where $a \in (0, \infty)$ is a parameter. The Poisson distribution is named after Simeon Poisson and is widely used to model the number of “random points” in a region of time or space; the parameter a is proportional to the size of the region. The Poisson distribution is studied in detail in the chapter on the Poisson Process.

If N has the Poisson distribution with parameter a then $\mathbb{E}(N) = a$. Thus, the parameter of the Poisson distribution is the mean of the distribution.

Proof

The proof depends on the standard series for the exponential function

$$\mathbb{E}(N) = \sum_{n=0}^{\infty} n e^{-a} \frac{a^n}{n!} = e^{-a} \sum_{n=1}^{\infty} \frac{a^n}{(n-1)!} = e^{-a} a \sum_{n=1}^{\infty} \frac{a^{n-1}}{(n-1)!} = e^{-a} a e^a = a. \quad (4.1.30)$$

In the Poisson experiment, the parameter is $a = rt$. Vary the parameter and note the shape of the probability density function and the location of the mean. For various values of the parameter, run the experiment 1000 times and compare the sample mean to the distribution mean.

The Exponential Distribution

Recall that the *exponential distribution* is a continuous distribution with probability density function f given by

$$f(t) = r e^{-rt}, \quad t \in [0, \infty) \quad (4.1.31)$$

where $r \in (0, \infty)$ is the *rate parameter*. This distribution is widely used to model failure times and other “arrival times”; in particular, the distribution governs the time between arrivals in the Poisson model. The exponential distribution is studied in detail in the chapter on the Poisson Process.

Suppose that T has the exponential distribution with rate parameter r . Then $\mathbb{E}(T) = 1/r$.

Proof

This result follows from the definition and an integration by parts:

$$\mathbb{E}(T) = \int_0^{\infty} t r e^{-rt} dt = -te^{-rt} \Big|_0^{\infty} + \int_0^{\infty} e^{-rt} dt = 0 - \frac{1}{r} e^{-rt} \Big|_0^{\infty} = \frac{1}{r} \quad (4.1.32)$$

Recall that the mode of T is 0 and the median of T is $\ln 2/r$. Note how these measures of center are ordered: $0 < \ln 2/r < 1/r$

In the gamma experiment, set $n = 1$ to get the exponential distribution. This app simulates the first arrival in a Poisson process. Vary r with the scroll bar and note the position of the mean relative to the graph of the probability density function. For selected values of r , run the experiment 1000 times and compare the sample mean to the distribution mean.

Suppose again that T has the exponential distribution with rate parameter r and suppose that $t > 0$. Find $\mathbb{E}(T \mid T > t)$.

Answer

$$t + \frac{1}{r}$$

The Gamma Distribution

Recall that the *gamma distribution* is a continuous distribution with probability density function f given by

$$f(t) = r^n \frac{t^{n-1}}{(n-1)!} e^{-rt}, \quad t \in [0, \infty) \quad (4.1.33)$$

where $n \in \mathbb{N}_+$ is the *shape parameter* and $r \in (0, \infty)$ is the *rate parameter*. This distribution is widely used to model failure times and other “arrival times”, and in particular, models the n th arrival in the Poisson process. Thus it follows that if (X_1, X_2, \dots, X_n) is a sequence of independent random variables, each having the exponential distribution with rate parameter r , then $T = \sum_{i=1}^n X_i$ has the gamma distribution with shape parameter n and rate parameter r . The gamma distribution is studied in more generality, with non-integer shape parameters, in the chapter on the Special Distributions.

Suppose that T has the gamma distribution with shape parameter n and rate parameter r . Then $\mathbb{E}(T) = n/r$.

Proof from the definition

The proof is by induction on n , so let μ_n denote the mean when the shape parameter is $n \in \mathbb{N}_+$. When $n = 1$, we have the exponential distribution with rate parameter r , so we know $\mu_1 = 1/r$ by our [result above](#). Suppose that $\mu_n = r/n$ for a given $n \in \mathbb{N}_+$. Then

$$\mu_{n+1} = \int_0^{\infty} t r^{n+1} \frac{t^n}{n!} e^{-rt} dt = \int_0^{\infty} r^{n+1} \frac{t^{n+1}}{n!} e^{-rt} dt \quad (4.1.34)$$

Integrate by parts with $u = \frac{t^{n+1}}{n!}$, $dv = r^{n+1} e^{-rt} dt$ so that $du = (n+1) \frac{t^n}{n!} dt$ and $v = -r^n e^{-rt}$. Then

$$\mu_{n+1} = (n+1) \int_0^{\infty} r^n \frac{t^n}{n!} e^{-rt} dt = \frac{n+1}{n} \int_0^{\infty} t r^n \frac{t^{n-1}}{(n-1)!} e^{-rt} dt \quad (4.1.35)$$

But the last integral is μ_n , so by the induction hypothesis, $\mu_{n+1} = \frac{n+1}{n} \frac{n}{r} = \frac{n+1}{r}$.

Proof using the additive property

The result follows immediately from the [additive property](#) and the fact that T can be represented in the form $T = \sum_{i=1}^n X_i$ where X_i has the exponential distribution with parameter r for each $i \in \{1, 2, \dots, n\}$.

Note again how much easier and more intuitive the second proof is than the first.

Open the gamma experiment, which simulates the arrival times in the Poisson process. Vary the parameters and note the position of the mean relative to the graph of the probability density function. For selected parameter values, run the experiment 1000 times and compare the sample mean to the distribution mean.

Beta Distributions

The distributions in this subsection belong to the family of *beta distributions*, which are widely used to model random proportions and probabilities. The beta distribution is studied in detail in the chapter on Special Distributions.

Suppose that X has probability density function f given by $f(x) = 3x^2$ for $x \in [0, 1]$.

1. Find the mean of X .

2. Find the mode of X .
3. Find the median of X .
4. Sketch the graph of f and show the location of the mean, median, and mode on the x -axis.

Answer

1. $\frac{3}{4}$
2. 1
3. $(\frac{1}{2})^{1/3}$

In the special distribution simulator, select the beta distribution and set $a = 3$ and $b = 1$ to get the distribution in the last exercise. Run the experiment 1000 times and compare the sample mean to the distribution mean.

Suppose that a sphere has a random radius R with probability density function f given by $f(r) = 12r^2(1-r)$ for $r \in [0, 1]$. Find the expected value of each of the following:

1. The circumference $C = 2\pi R$
2. The surface area $A = 4\pi R^2$
3. The volume $V = \frac{4}{3}\pi R^3$

Answer

1. $\frac{6}{5}\pi$
2. $\frac{8}{5}\pi$
3. $\frac{8}{21}\pi$

Suppose that X has probability density function f given by $f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$ for $x \in (0, 1)$.

1. Find the mean of X .
2. Find median of X .
3. Note that f is unbounded, so X does not have a mode.
4. Sketch the graph of f and show the location of the mean and median on the x -axis.

Answer

1. $\frac{1}{2}$
2. $\frac{1}{2}$

The particular beta distribution in the last exercise is also known as the (standard) *arcsine distribution*. It governs the last time that the Brownian motion process hits 0 during the time interval $[0, 1]$. The arcsine distribution is studied in more generality in the chapter on Special Distributions.

Open the Brownian motion experiment and select the last zero. Run the simulation 1000 times and compare the sample mean to the distribution mean.

Suppose that the grades on a test are described by the random variable $Y = 100X$ where X has the beta distribution with probability density function f given by $f(x) = 12x(1-x)^2$ for $x \in [0, 1]$. The grades are generally low, so the teacher decides to “curve” the grades using the transformation $Z = 10\sqrt{Y} = 100\sqrt{X}$. Find the expected value of each of the following variables

1. X
2. Y
3. Z

Answer

1. $\mathbb{E}(X) = \frac{2}{5}$
2. $\mathbb{E}(Y) = 40$
3. $\mathbb{E}(Z) = \frac{1280}{21} \approx 60.95$

The Pareto Distribution

Recall that the *Pareto distribution* is a continuous distribution with probability density function f given by

$$f(x) = \frac{a}{x^{a+1}}, \quad x \in [1, \infty) \quad (4.1.36)$$

where $a \in (0, \infty)$ is a parameter. The Pareto distribution is named for Vilfredo Pareto. It is a heavy-tailed distribution that is widely used to model certain financial variables. The Pareto distribution is studied in detail in the chapter on Special Distributions.

Suppose that X has the Pareto distribution with shape parameter a . Then

1. $\mathbb{E}(X) = \infty$ if $0 < a \leq 1$
2. $\mathbb{E}(X) = \frac{a}{a-1}$ if $a > 1$

Proof

1. If $0 < a < 1$,

$$\mathbb{E}(X) = \int_1^\infty x \frac{a}{x^{a+1}} dx = \int_1^\infty \frac{a}{x^a} dx = \frac{a}{-a+1} x^{-a+1} \Big|_1^\infty = \infty \quad (4.1.37)$$

since the exponent $-a+1 > 0$. If $a = 1$, $\mathbb{E}(X) = \int_1^\infty x \frac{1}{x^2} dx = \int_1^\infty \frac{1}{x} dx = \ln x \Big|_1^\infty = \infty$.

2. If $a > 1$ then

$$\mathbb{E}(X) = \int_1^\infty x \frac{a}{x^{a+1}} dx = \int_1^\infty \frac{a}{x^a} dx = \frac{a}{-a+1} x^{-a+1} \Big|_1^\infty = \frac{a}{a-1} \quad (4.1.38)$$

The previous exercise gives us our first example of a distribution whose mean is infinite.

In the special distribution simulator, select the Pareto distribution. Note the shape of the probability density function and the location of the mean. For the following values of the shape parameter a , run the experiment 1000 times and note the behavior of the empirical mean.

1. $a = 1$
2. $a = 2$
3. $a = 3$.

The Cauchy Distribution

Recall that the (standard) *Cauchy distribution* has probability density function f given by

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad x \in \mathbb{R} \quad (4.1.39)$$

This distribution is named for Augustin Cauchy. The Cauchy distributions is studied in detail in the chapter on Special Distributions.

If X has the Cauchy distribution then $\mathbb{E}(X)$ does not exist.

Proof

By definition,

$$\mathbb{E}(X) = \int_{-\infty}^\infty x \frac{1}{\pi(1+x^2)} dx = \frac{1}{2\pi} \ln(1+x^2) \Big|_{-\infty}^\infty \quad (4.1.40)$$

which evaluates to the meaningless expression $\infty - \infty$.

Note that the graph of f is symmetric about 0 and is unimodal. Thus, the mode and median of X are both 0. By the [symmetry result](#), if X had a mean, the mean would be 0 also, but alas the mean does not exist. Moreover, the non-existence of the mean is not just a pedantic technicality. If we think of the probability distribution as a mass distribution, then the moment to the right of a is $\int_a^\infty (x-a)f(x) dx = \infty$ and the moment to the left of a is $\int_{-\infty}^a (x-a)f(x) dx = -\infty$ for every $a \in \mathbb{R}$. The center of mass simply does not exist. Probabilistically, the law of large numbers fails, as you can see in the following simulation exercise:

In the Cauchy experiment (with the default parameter values), a light source is 1 unit from position 0 on an infinite straight wall. The angle that the light makes with the perpendicular is uniformly distributed on the interval $(-\frac{\pi}{2}, \frac{\pi}{2})$, so that the position of the light beam on the wall has the Cauchy distribution. Run the simulation 1000 times and note the behavior of the empirical mean.

The Normal Distribution

Recall that the *standard normal distribution* is a continuous distribution with density function ϕ given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}, \quad z \in \mathbb{R} \quad (4.1.41)$$

Normal distributions are widely used to model physical measurements subject to small, random errors and are studied in detail in the chapter on Special Distributions.

If Z has the standard normal distribution then $\mathbb{E}(Z) = 0$.

Proof

Using a simple change of variables, we have

$$\mathbb{E}(Z) = \int_{-\infty}^{\infty} z \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} dz = -\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} \Big|_{-\infty}^{\infty} = 0 - 0 \quad (4.1.42)$$

The standard normal distribution is unimodal and symmetric about 0. Thus, the median, mean, and mode all agree. More generally, for $\mu \in (-\infty, \infty)$ and $\sigma \in (0, \infty)$, recall that $X = \mu + \sigma Z$ has the normal distribution with *location parameter* μ and *scale parameter* σ . X has probability density function f given by

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right], \quad x \in \mathbb{R} \quad (4.1.43)$$

The location parameter is the mean of the distribution:

If X has the normal distribution with location parameter $\mu \in \mathbb{R}$ and scale parameter $\sigma \in (0, \infty)$, then $\mathbb{E}(X) = \mu$

Proof

Of course we could use the definition, but a proof using [linearity](#) and the representation in terms of the standard normal distribution is trivial: $\mathbb{E}(X) = \mu + \sigma \mathbb{E}(Z) = \mu$.

In the special distribution simulator, select the normal distribution. Vary the parameters and note the location of the mean. For selected parameter values, run the simulation 1000 times and compare the sample mean to the distribution mean.

Additional Exercises

Suppose that (X, Y) has probability density function f given by $f(x, y) = x + y$ for $(x, y) \in [0, 1] \times [0, 1]$. Find the following expected values:

1. $\mathbb{E}(X)$
2. $\mathbb{E}(X^2 Y)$
3. $\mathbb{E}(X^2 + Y^2)$
4. $\mathbb{E}(XY \mid Y > X)$

Answer

1. $\frac{7}{12}$
2. $\frac{17}{72}$
3. $\frac{5}{6}$
4. $\frac{1}{3}$

Suppose that N has a discrete distribution with probability density function f given by $f(n) = \frac{1}{50}n^2(5-n)$ for $n \in \{1, 2, 3, 4\}$. Find each of the following:

1. The median of N .
2. The mode of N
3. $\mathbb{E}(N)$.
4. $\mathbb{E}(N^2)$
5. $\mathbb{E}(1/N)$.
6. $\mathbb{E}(1/N^2)$.

Answer

1. 3
2. 3
3. $\frac{73}{25}$
4. $\frac{47}{5}$
5. $\frac{2}{5}$
6. $\frac{1}{5}$

Suppose that X and Y are real-valued random variables with $\mathbb{E}(X) = 5$ and $\mathbb{E}(Y) = -2$. Find $\mathbb{E}(3X + 4Y - 7)$.

Answer

0

Suppose that X and Y are real-valued, independent random variables, and that $\mathbb{E}(X) = 5$ and $\mathbb{E}(Y) = -2$. Find $\mathbb{E}[(3X - 4)(2Y + 7)]$.

Answer

33

Suppose that there are 5 duck hunters, each a perfect shot. A flock of 10 ducks fly over, and each hunter selects one duck at random and shoots. Find the expected number of ducks killed.

Solution

Number the ducks from 1 to 10. For $k \in \{1, 2, \dots, 10\}$ let X_k be the indicator variable that takes the value 1 if duck k is killed and 0 otherwise. Duck k is killed if at least one of the hunters selects her, so $\mathbb{E}(X_k) = \mathbb{P}(X_k = 1) = 1 - \left(\frac{9}{10}\right)^5$. The number of ducks killed is $N = \sum_{k=1}^{10} X_k$ so $\mathbb{E}(N) = 10 \left[1 - \left(\frac{9}{10}\right)^5\right] = 4.095$

For a more complete analysis of the duck hunter problem, see The Number of Distinct Sample Values in the chapter on Finite Sampling Models.

Consider the following game: An urn initially contains one red and one green ball. A ball is selected at random, and if the ball is green, the game is over. If the ball is red, the ball is returned to the urn, another red ball is added, and the game continues. At each stage, a ball is selected at random, and if the ball is green, the game is over. If the ball is red, the ball is returned to the urn, another red ball is added, and the game continues. Let X denote the length of the game (that is, the number of selections required to obtain a green ball). Find $\mathbb{E}(X)$.

Solution

The probability density function f of X was found in the section on discrete distributions: $f(x) = \frac{1}{x(x+1)}$ for $x \in \mathbb{N}_+$. The expected length of the game is infinite:

$$\mathbb{E}(X) = \sum_{x=1}^{\infty} x \frac{1}{x(x+1)} = \sum_{x=1}^{\infty} \frac{1}{x+1} = \infty \quad (4.1.44)$$

4.2: Additional Properties

In this section, we study some properties of expected value that are a bit more specialized than the basic properties considered in the previous section. Nonetheless, the new results are also very important. They include two fundamental inequalities as well as special formulas for the expected value of a nonnegative variable. As usual, unless otherwise noted, we assume that the referenced expected values exist.

Basic Theory

Markov's Inequality

Our first result is known as *Markov's inequality* (named after Andrei Markov). It gives an upper bound for the tail probability of a nonnegative random variable in terms of the expected value of the variable.

If X is a nonnegative random variable, then

$$\mathbb{P}(X \geq x) \leq \frac{\mathbb{E}(X)}{x}, \quad x > 0 \quad (4.2.1)$$

Proof

For $x > 0$, note that $x \cdot \mathbf{1}(X \geq x) \leq X$. Taking expected values through this inequality gives $x\mathbb{P}(X \geq x) \leq \mathbb{E}(X)$.

The upper bound in Markov's inequality may be rather crude. In fact, it's quite possible that $\mathbb{E}(X)/x \geq 1$, in which case the bound is worthless. However, the real value of Markov's inequality lies in the fact that it holds with no assumptions whatsoever on the distribution of X (other than that X be nonnegative). Also, as an [example below](#) shows, the inequality is *tight* in the sense that equality can hold for a given x . Here is a simple corollary of Markov's inequality.

If X is a real-valued random variable and $k \in (0, \infty)$ then

$$\mathbb{P}(|X| \geq x) \leq \frac{\mathbb{E}(|X|^k)}{x^k} \quad x > 0 \quad (4.2.2)$$

Proof

Since $k \geq 0$, the function $x \mapsto x^k$ is strictly increasing on $[0, \infty)$. Hence using Markov's inequality,

$$\mathbb{P}(|X| \geq x) = \mathbb{P}(|X|^k \geq x^k) \leq \frac{\mathbb{E}(|X|^k)}{x^k} \quad (4.2.3)$$

In this corollary of Markov's inequality, we could try to find $k > 0$ so that $\mathbb{E}(|X|^k)/x^k$ is minimized, thus giving the tightest bound on $\mathbb{P}(|X| \geq x)$.

Right Distribution Function

Our next few results give alternative ways to compute the expected value of a nonnegative random variable by means of the right-tail distribution function. This function also known as the *reliability function* if the variable represents the lifetime of a device.

If X is a nonnegative random variable then

$$\mathbb{E}(X) = \int_0^\infty \mathbb{P}(X > x) dx \quad (4.2.4)$$

Proof

A proof can be constructed by expressing $\mathbb{P}(X > x)$ in terms of the probability density function of X , as a sum in the discrete case or an integral in the continuous case. Then in the expression $\int_0^\infty \mathbb{P}(X > x) dx$ interchange the integral and the sum (in the discrete case) or the two integrals (in the continuous case). There is a much more elegant proof if we use the fact that we can interchange expected values and integrals when the integrand is nonnegative:

$$\int_0^\infty \mathbb{P}(X > x) dx = \int_0^\infty \mathbb{E}[\mathbf{1}(X > x)] dx = \mathbb{E}\left(\int_0^\infty \mathbf{1}(X > x) dx\right) = \mathbb{E}\left(\int_0^X 1 dx\right) = \mathbb{E}(X) \quad (4.2.5)$$

This interchange is a special case of *Fubini's theorem*, named for the Italian mathematician Guido Fubini. See the advanced section on expected value as an integral for more details.

Here is a slightly more general result:

If X is a nonnegative random variable and $k \in (0, \infty)$ then

$$\mathbb{E}(X^k) = \int_0^\infty kx^{k-1} \mathbb{P}(X > x) dx \quad (4.2.6)$$

Proof

The same basic proof works:

$$\int_0^\infty kx^{k-1} \mathbb{P}(X > x) dx = \int_0^\infty kx^{k-1} \mathbb{E}[\mathbf{1}(X > x)] dx = \mathbb{E}\left(\int_0^\infty kx^{k-1} \mathbf{1}(X > x) dx\right) = \mathbb{E}\left(\int_0^X kx^{k-1} dx\right) = \mathbb{E}(X^k) \quad (4.2.7)$$

The following result is similar to the [theorem above](#), but is specialized to nonnegative integer valued variables:

Suppose that N has a discrete distribution, taking values in \mathbb{N} . Then

$$\mathbb{E}(N) = \sum_{n=0}^\infty \mathbb{P}(N > n) = \sum_{n=1}^\infty \mathbb{P}(N \geq n) \quad (4.2.8)$$

Proof

First, the two sums on the right are equivalent by a simple change of variables. A proof can be constructed by expressing $\mathbb{P}(N > n)$ as a sum in terms of the probability density function of N . Then in the expression $\sum_{n=0}^\infty \mathbb{P}(N > n)$ interchange the two sums. Here is a more elegant proof:

$$\sum_{n=1}^\infty \mathbb{P}(N \geq n) = \sum_{n=1}^\infty \mathbb{E}[\mathbf{1}(N \geq n)] = \mathbb{E}\left(\sum_{n=1}^\infty \mathbf{1}(N \geq n)\right) = \mathbb{E}\left(\sum_{n=1}^N 1\right) = \mathbb{E}(N) \quad (4.2.9)$$

This interchange is a special case of a general rule that allows the interchange of expected value and an infinite series, when the terms are nonnegative. See the advanced section on expected value as an integral for more details.

A General Definition

The [special expected value formula](#) for nonnegative variables can be used as the basis of a general formulation of expected value that would work for discrete, continuous, or even mixed distributions, and would not require the assumption of the existence of probability density functions. First, the special formula is taken as the definition of $\mathbb{E}(X)$ if X is nonnegative.

If X is a nonnegative random variable, define

$$\mathbb{E}(X) = \int_0^\infty \mathbb{P}(X > x) dx \quad (4.2.10)$$

Next, for $x \in \mathbb{R}$, recall that the *positive and negative parts* of x are $x^+ = \max\{x, 0\}$ and $x^- = \max\{0, -x\}$.

For $x \in \mathbb{R}$,

1. $x^+ \geq 0, x^- \geq 0$
2. $x = x^+ - x^-$
3. $|x| = x^+ + x^-$

Now, if X is a real-valued random variable, then X^+ and X^- , the positive and negative parts of X , are nonnegative random variables, so their expected values are defined as above. The definition of $\mathbb{E}(X)$ is then natural, anticipating of course the linearity property.

If X is a real-valued random variable, define $\mathbb{E}(X) = \mathbb{E}(X^+) - \mathbb{E}(X^-)$, assuming that at least one of the expected values on the right is finite.

The usual formulas for expected value in terms of the probability density function, for discrete, continuous, or mixed distributions, would now be proven as theorems. We will not go further in this direction, however, since the most complete and general definition of expected value is given in the advanced section on expected value as an integral.

The Change of Variables Theorem

Suppose that X takes values in S and has probability density function f . Suppose also that $r: S \rightarrow \mathbb{R}$, so that $r(X)$ is a real-valued random variable. The *change of variables theorem* gives a formula for computing $\mathbb{E}[r(X)]$ without having to first find the probability density function of $r(X)$. If S is countable, so that X has a discrete distribution, then

$$\mathbb{E}[r(X)] = \sum_{x \in S} r(x)f(x) \quad (4.2.11)$$

If $S \subseteq \mathbb{R}^n$ and X has a continuous distribution on S then

$$\mathbb{E}[r(X)] = \int_S r(x)f(x) dx \quad (4.2.12)$$

In both cases, of course, we assume that the expected values exist. In the previous section on basic properties, we proved the change of variables theorem when X has a discrete distribution and when X has a continuous distribution but r has countable range. Now we can finally finish our proof in the continuous case.

Suppose that X has a continuous distribution on S with probability density function f , and $r : S \rightarrow \mathbb{R}$. Then

$$\mathbb{E}[r(X)] = \int_S r(x)f(x) dx \quad (4.2.13)$$

Proof

Suppose first that r is nonnegative. From the [theorem above](#),

$$\mathbb{E}[r(X)] = \int_0^\infty \mathbb{P}[r(X) > t] dt = \int_0^\infty \int_{r^{-1}(t, \infty)} f(x) dx dt = \int_S \int_0^{r(x)} f(x) dt dx = \int_S r(x)f(x) dx \quad (4.2.14)$$

For general r , we decompose into positive and negative parts, and use the result just established.

$$\mathbb{E}[r(X)] = \mathbb{E}[r^+(X) - r^-(X)] = \mathbb{E}[r^+(X)] - \mathbb{E}[r^-(X)] \quad (4.2.15)$$

$$= \int_S r^+(x)f(x) dx - \int_S r^-(x)f(x) dx = \int_S [r^+(x) - r^-(x)] f(x) dx = \int_S r(x)f(x) dx \quad (4.2.16)$$

Jensens's Inequality

Our next sequence of exercises will establish an important inequality known as *Jensen's inequality*, named for Johan Jensen. First we need a definition.

A real-valued function g defined on an interval $S \subseteq \mathbb{R}$ is said to be *convex* (or *concave upward*) on S if for each $t \in S$, there exist numbers a and b (that may depend on t), such that

1. $a + bt = g(t)$
2. $a + bx \leq g(x)$ for all $x \in S$

The graph of $x \mapsto a + bx$ is called a *supporting line* for g at t .

Thus, a convex function has *at least one* supporting line at each point in the domain

Figure 4.2.1: A convex function and several supporting lines

You may be more familiar with convexity in terms of the following theorem from calculus: If g has a continuous, non-negative second derivative on S , then g is convex on S (since the tangent line at t is a supporting line at t for each $t \in S$). The next result is the single variable version of Jensen's inequality

If X takes values in an interval S and $g : S \rightarrow \mathbb{R}$ is convex on S , then

$$\mathbb{E}[g(X)] \geq g[\mathbb{E}(X)] \quad (4.2.17)$$

Proof

Note that $\mathbb{E}(X) \in S$ so let $y = a + bx$ be a supporting line for g at $\mathbb{E}(X)$. Thus $a + b\mathbb{E}(X) = g[\mathbb{E}(X)]$ and $a + bX \leq g(X)$. Taking expected values through the inequality gives

$$a + b\mathbb{E}(X) = g[\mathbb{E}(X)] \leq \mathbb{E}[g(X)] \quad (4.2.18)$$

Jensens's inequality extends easily to higher dimensions. The 2-dimensional version is particularly important, because it will be used to derive several special inequalities in the section on vector spaces of random variables. We need two definitions.

A set $S \subseteq \mathbb{R}^n$ is *convex* if for every pair of points in S , the line segment connecting those points also lies in S . That is, if $\mathbf{x}, \mathbf{y} \in S$ and $p \in [0, 1]$ then $p\mathbf{x} + (1-p)\mathbf{y} \in S$.

Figure 4.2.2: A convex subset of \mathbb{R}^2

Suppose that $S \subseteq \mathbb{R}^n$ is convex. A function $g: S \rightarrow \mathbb{R}$ on S is *convex* (or *concave upward*) if for each $\mathbf{t} \in S$, there exist $\mathbf{a} \in \mathbb{R}$ and $\mathbf{b} \in \mathbb{R}^n$ (depending on \mathbf{t}) such that

1. $\mathbf{a} + \mathbf{b} \cdot \mathbf{t} = g(\mathbf{t})$
2. $\mathbf{a} + \mathbf{b} \cdot \mathbf{x} \leq g(\mathbf{x})$ for all $\mathbf{x} \in S$

The graph of $\mathbf{x} \mapsto \mathbf{a} + \mathbf{b} \cdot \mathbf{x}$ is called a *supporting hyperplane* for g at \mathbf{t} .

In \mathbb{R}^2 a supporting hyperplane is an ordinary plane. From calculus, if g has continuous second derivatives on S and has a *positive non-definite* second derivative matrix, then g is convex on S . Suppose now that $\mathbf{X} = (X_1, X_2, \dots, X_n)$ takes values in $S \subseteq \mathbb{R}^n$, and let $\mathbb{E}(\mathbf{X}) = (\mathbb{E}(X_1), \mathbb{E}(X_2), \dots, \mathbb{E}(X_n))$. The following result is the general version of Jensen's inequality.

If S is convex and $g: S \rightarrow \mathbb{R}$ is convex on S then

$$\mathbb{E}[g(\mathbf{X})] \geq g(\mathbb{E}(\mathbf{X})) \quad (4.2.19)$$

Proof

First $\mathbb{E}(\mathbf{X}) \in S$, so let $\mathbf{y} = \mathbf{a} + \mathbf{b} \cdot \mathbf{x}$ be a supporting hyperplane for g at $\mathbb{E}(\mathbf{X})$. Thus $\mathbf{a} + \mathbf{b} \cdot \mathbb{E}(\mathbf{X}) = g(\mathbb{E}(\mathbf{X}))$ and $\mathbf{a} + \mathbf{b} \cdot \mathbf{X} \leq g(\mathbf{X})$. Taking expected values through the inequality gives

$$\mathbf{a} + \mathbf{b} \cdot \mathbb{E}(\mathbf{X}) = g(\mathbb{E}(\mathbf{X})) \leq \mathbb{E}[g(\mathbf{X})] \quad (4.2.20)$$

We will study the expected value of random vectors and matrices in more detail in a later section. In both the one and n -dimensional cases, a function $g: S \rightarrow \mathbb{R}$ is *concave* (or *concave downward*) if the inequality in the definition is reversed. Jensen's inequality also reverses.

Expected Value in Terms of the Quantile Function

If X has a continuous distribution with support on an interval of \mathbb{R} , then there is a simple (but not well known) formula for the expected value of X as the integral the quantile function of X . Here is the general result:

Suppose that X has a continuous distribution with support on an interval $(a, b) \subseteq \mathbb{R}$. Let F denote the cumulative distribution function of X so that F^{-1} is the quantile function of X . If $g: (a, b) \rightarrow \mathbb{R}$ then (assuming that the expected value exists),

$$\mathbb{E}[g(X)] = \int_0^1 g[F^{-1}(p)] dp, \quad n \in \mathbb{N} \quad (4.2.21)$$

Proof

Suppose that X has probability density function f , although the theorem is true without this assumption. Under the assumption that X has a continuous distribution with support on the interval (a, b) , the distribution function F is strictly increasing on (a, b) , and the quantile function F^{-1} is the ordinary inverse of F . Substituting $p = F(x)$, $dp = F'(x) dx = f(x) dx$ we have

$$\int_0^1 g[F^{-1}(p)] dp = \int_a^b g(F^{-1}[F(x)]) f(x) dx = \int_a^b g(x) f(x) dx = \mathbb{E}[g(X)] \quad (4.2.22)$$

So in particular, $\mathbb{E}(X) = \int_0^1 F^{-1}(p) dp$.

Examples and Applications

Let $a \in (0, \infty)$ and let $\mathbb{P}(X = a) = 1$, so that X is a constant random variable. Show that Markov's inequality is in fact equality at $x = a$.

Solution

Of course $\mathbb{E}(X) = a$. Hence $\mathbb{P}(X \geq a) = 1$ and $\mathbb{E}(X)/a = 1$.

The Exponential Distribution

Recall that the *exponential distribution* is a continuous distribution with probability density function f given by

$$f(t) = re^{-rt}, \quad t \in [0, \infty) \quad (4.2.23)$$

where $r \in (0, \infty)$ is the *rate parameter*. This distribution is widely used to model failure times and other “arrival times”; in particular, the distribution governs the time between arrivals in the Poisson model. The exponential distribution is studied in detail in the chapter on the Poisson Process.

Suppose that X has exponential distribution with rate parameter r .

1. Find $\mathbb{E}(X)$ using the [right distribution formula](#).
2. Find $\mathbb{E}(X)$ using the [quantile function formula](#).
3. Compute both sides of [Markov's inequality](#).

Answer

1. $\int_0^\infty e^{-rt} dt = \frac{1}{r}$
2. $\int_0^1 -\frac{1}{r} \ln(1-p) dp = \frac{1}{r}$
3. $e^{-rt} < \frac{1}{rt}$ for $t > 0$

Open the gamma experiment. Keep the default value of the stopping parameter ($n = 1$), which gives the exponential distribution. Vary the rate parameter r and note the shape of the probability density function and the location of the mean. For various values of the rate parameter, run the experiment 1000 times and compare the sample mean with the distribution mean.

The Geometric Distribution

Recall that *Bernoulli trials* are independent trials each with two outcomes, which in the language of reliability, are called *success* and *failure*. The probability of success on each trial is $p \in [0, 1]$. A separate chapter on Bernoulli Trials explores this random process in more detail. It is named for Jacob Bernoulli. If $p \in (0, 1)$, the trial number N of the first success has the geometric distribution on \mathbb{N}_+ with success parameter p . The probability density function f of N is given by

$$f(n) = p(1-p)^{n-1}, \quad n \in \mathbb{N}_+ \quad (4.2.24)$$

Suppose that N has the geometric distribution on \mathbb{N}_+ with parameter $p \in (0, 1)$.

1. Find $\mathbb{E}(N)$ using the [right distribution function formula](#).
2. Compute both sides of [Markov's inequality](#).
3. Find $\mathbb{E}(N \mid N \text{ is even})$.

Answer

1. $\sum_{n=0}^\infty (1-p)^n = \frac{1}{p}$
2. $(1-p)^{n-1} < \frac{1}{np}, \quad n \in \mathbb{N}_+$
3. $\frac{2(1-p)^2}{p(2-p)^2}$

Open the negative binomial experiment. Keep the default value of the stopping parameter ($k = 1$), which gives the geometric distribution. Vary the success parameter p and note the shape of the probability density function and the location of the mean. For various values of the success parameter, run the experiment 1000 times and compare the sample mean with the distribution mean.

The Pareto Distribution

Recall that the *Pareto distribution* is a continuous distribution with probability density function f given by

$$f(x) = \frac{a}{x^{a+1}}, \quad x \in [1, \infty) \quad (4.2.25)$$

where $a \in (0, \infty)$ is a parameter. The Pareto distribution is named for Vilfredo Pareto. It is a heavy-tailed distribution that is widely used to model certain financial variables. The Pareto distribution is studied in detail in the chapter on Special Distributions.

Suppose that X has the Pareto distribution with parameter $a > 1$.

1. Find $\mathbb{E}(X)$ using the [right distribution function formula](#).
2. Find $\mathbb{E}(X)$ using the [quantile function formula](#).
3. Find $\mathbb{E}(1/X)$.

4. Show that $x \mapsto 1/x$ is convex on $(0, \infty)$.
5. Verify [Jensen's inequality](#) by comparing $\mathbb{E}(1/X)$ and $1/\mathbb{E}(X)$.

Answer

1. $\int_0^1 1 \, dx + \int_1^\infty x^{-a} \, dx = \frac{a}{a-1}$
2. $\int_0^1 (1-p)^{-1/a} \, dp = \frac{a}{a-1}$
3. $\frac{a}{a+1}$
4. The convexity of $1/x$ is clear from the graph. Note also that $\frac{d^2}{dx^2} \frac{1}{x} = \frac{2}{x^3} > 0$ for $x > 0$.
5. $\frac{a}{a+1} > \frac{a-1}{a}$

Open the special distribution simulator and select the Pareto distribution. Keep the default value of the scale parameter. Vary the shape parameter and note the shape of the probability density function and the location of the mean. For various values of the shape parameter, run the experiment 1000 times and compare the sample mean with the distribution mean.

A Bivariate Distribution

Suppose that (X, Y) has probability density function f given by $f(x, y) = 2(x + y)$ for $0 \leq x \leq y \leq 1$.

1. Show that the domain of f is a convex set.
2. Show that $(x, y) \mapsto x^2 + y^2$ is convex on the domain of f .
3. Compute $\mathbb{E}(X^2 + Y^2)$.
4. Compute $[\mathbb{E}(X)]^2 + [\mathbb{E}(Y)]^2$.
5. Verify [Jensen's inequality](#) by comparing (b) and (c).

Answer

1. Note that the domain is a triangular region.
2. The second derivative matrix is $\begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$.
3. $\frac{5}{6}$
4. $\frac{53}{72}$
5. $\frac{5}{6} > \frac{53}{72}$

The Arithmetic and Geometric Means

Suppose that $\{x_1, x_2, \dots, x_n\}$ is a set of positive numbers. The *arithmetic mean* is at least as large as the *geometric mean*:

$$\left(\prod_{i=1}^n x_i \right)^{1/n} \leq \frac{1}{n} \sum_{i=1}^n x_i \quad (4.2.26)$$

Proof

Let X be uniformly distributed on $\{x_1, x_2, \dots, x_n\}$. We apply [Jensen's inequality](#) with the natural logarithm function, which is concave on $(0, \infty)$:

$$\mathbb{E}(\ln X) = \frac{1}{n} \sum_{i=1}^n \ln x_i = \ln \left[\left(\prod_{i=1}^n x_i \right)^{1/n} \right] \leq \ln[\mathbb{E}(X)] = \ln \left(\frac{1}{n} \sum_{i=1}^n x_i \right) \quad (4.2.27)$$

Taking exponentials of each side gives the inequality.

4.3: Variance

Recall the **expected value** of a real-valued random variable is the mean of the variable, and is a measure of the center of the distribution. Recall also that by taking the expected value of various transformations of the variable, we can measure other interesting characteristics of the distribution. In this section, we will study expected values that measure the spread of the distribution about the mean.

Basic Theory

Definitions and Interpretations

As usual, we start with a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} the collection of events, and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) . Suppose that X is a random variable for the experiment, taking values in $S \subseteq \mathbb{R}$. Recall that $\mathbb{E}(X)$, the expected value (or mean) of X gives the center of the distribution of X .

The *variance* and *standard deviation* of X are defined by

1. $\text{var}(X) = \mathbb{E}([X - \mathbb{E}(X)]^2)$
2. $\text{sd}(X) = \sqrt{\text{var}(X)}$

Implicit in the definition is the assumption that the mean $\mathbb{E}(X)$ exists, as a real number. If this is not the case, then $\text{var}(X)$ (and hence also $\text{sd}(X)$) are undefined. Even if $\mathbb{E}(X)$ does exist as a real number, it's possible that $\text{var}(X) = \infty$. For the remainder of our discussion of the basic theory, we will assume that expected values that are mentioned exist as real numbers.

The variance and standard deviation of X are both measures of the spread of the distribution about the mean. Variance (as we will see) has nicer mathematical properties, but its physical unit is the square of that of X . Standard deviation, on the other hand, is not as nice mathematically, but has the advantage that its physical unit is the same as that of X . When the random variable X is understood, the standard deviation is often denoted by σ , so that the variance is σ^2 .

Recall that the *second moment* of X about $a \in \mathbb{R}$ is $\mathbb{E}[(X - a)^2]$. Thus, the variance is the second moment of X about the mean $\mu = \mathbb{E}(X)$, or equivalently, the *second central moment* of X . In general, the second moment of X about $a \in \mathbb{R}$ can also be thought of as the *mean square error* if the constant a is used as an *estimate* of X . In addition, second moments have a nice interpretation in physics. If we think of the distribution of X as a mass distribution in \mathbb{R} , then the second moment of X about $a \in \mathbb{R}$ is the *moment of inertia* of the mass distribution about a . This is a measure of the resistance of the mass distribution to any change in its rotational motion about a . In particular, the variance of X is the moment of inertia of the mass distribution about the center of mass μ .

Figure 4.3.1: The moment of inertia about a .

The mean square error (or equivalently the moment of inertia) about a is minimized when $a = \mu$:

Let $\text{mse}(a) = \mathbb{E}[(X - a)^2]$ for $a \in \mathbb{R}$. Then mse is minimized when $a = \mu$, and the minimum value is σ^2 .

Proof

Figure 4.3.2: $\text{mse}(a)$ is minimized when $a = \mu$.

The relationship between measures of center and measures of spread is studied in more detail in the advanced section on vector spaces of random variables.

Properties

The following exercises give some basic properties of variance, which in turn rely on basic properties of expected value. As usual, be sure to try the proofs yourself before reading the ones in the text. Our first results are computational formulas based on the change of variables formula for expected value

Let $\mu = \mathbb{E}(X)$.

1. If X has a discrete distribution with probability density function f , then $\text{var}(X) = \sum_{x \in S} (x - \mu)^2 f(x)$.
2. If X has a continuous distribution with probability density function f , then $\text{var}(X) = \int_S (x - \mu)^2 f(x) dx$

Proof

1. This follows from the discrete version of the change of variables formula.
2. Similarly, this follows from the continuous version of the change of variables formula.

Our next result is a variance formula that is usually better than the definition for computational purposes.

$$\text{var}(X) = \mathbb{E}(X^2) - [\mathbb{E}(X)]^2.$$

Proof

Let $\mu = \mathbb{E}(X)$. Using the linearity of expected value we have

$$\text{var}(X) = \mathbb{E}[(X - \mu)^2] = \mathbb{E}(X^2 - 2\mu X + \mu^2) = \mathbb{E}(X^2) - 2\mu \mathbb{E}(X) + \mu^2 = \mathbb{E}(X^2) - 2\mu^2 + \mu^2 = \mathbb{E}(X^2) - \mu^2 \quad (4.3.1)$$

Of course, by the change of variables formula, $\mathbb{E}(X^2) = \sum_{x \in S} x^2 f(x)$ if X has a discrete distribution, and $\mathbb{E}(X^2) = \int_S x^2 f(x) dx$ if X has a continuous distribution. In both cases, f is the probability density function of X .

Variance is always nonnegative, since it's the expected value of a nonnegative random variable. Moreover, any random variable that really is *random* (not a constant) will have strictly positive variance.

The nonnegative property.

1. $\text{var}(X) \geq 0$
2. $\text{var}(X) = 0$ if and only if $\mathbb{P}(X = c) = 1$ for some constant c (and then of course, $\mathbb{E}(X) = c$).

Proof

These results follow from the basic positive property of expected value. Let $\mu = \mathbb{E}(X)$. First $(X - \mu)^2 \geq 0$ with probability 1 so $\mathbb{E}[(X - \mu)^2] \geq 0$. In addition, $\mathbb{E}[(X - \mu)^2] = 0$ if and only if $\mathbb{P}(X = \mu) = 1$.

Our next result shows how the variance and standard deviation are changed by a linear transformation of the random variable. In particular, note that variance, unlike general expected value, is not a linear operation. This is not really surprising since the variance is the expected value of a nonlinear function of the variable: $x \mapsto (x - \mu)^2$.

If $a, b \in \mathbb{R}$ then

1. $\text{var}(a + bX) = b^2 \text{var}(X)$
2. $\text{sd}(a + bX) = |b| \text{sd}(X)$

Proof

1. Let $\mu = \mathbb{E}(X)$. By linearity, $\mathbb{E}(a + bX) = a + b\mu$. Hence $\text{var}(a + bX) = \mathbb{E}([(a + bX) - (a + b\mu)]^2) = \mathbb{E}[b^2(X - \mu)^2] = b^2 \text{var}(X)$.
2. This result follows from (a) by taking square roots.

Recall that when $b > 0$, the linear transformation $x \mapsto a + bx$ is called a *location-scale* transformation and often corresponds to a change of location and change of scale in the physical units. For example, the change from inches to centimeters in a measurement of length is a scale transformation, and the change from Fahrenheit to Celsius in a measurement of temperature is both a location and scale transformation. The previous result shows that when a location-scale transformation is applied to a random variable, the standard deviation does not depend on the location parameter, but is multiplied by the scale factor. There is a particularly important location-scale transformation.

Suppose that X is a random variable with mean μ and variance σ^2 . The random variable Z defined as follows is the *standard score* of X .

$$Z = \frac{X - \mu}{\sigma} \quad (4.3.2)$$

1. $\mathbb{E}(Z) = 0$
2. $\text{var}(Z) = 1$

Proof

1. From the linearity of expected value, $\mathbb{E}(Z) = \frac{1}{\sigma} [\mathbb{E}(X) - \mu] = 0$
2. From the [scaling property](#), $\text{var}(Z) = \frac{1}{\sigma^2} \text{var}(X) = 1$.

Since X and its mean and standard deviation all have the same physical units, the standard score Z is dimensionless. It measures the directed distance from $\mathbb{E}(X)$ to X in terms of standard deviations.

Let Z denote the standard score of X , and suppose that $Y = a + bX$ where $a, b \in \mathbb{R}$ and $b \neq 0$.

1. If $b > 0$, the standard score of Y is Z .
2. If $b < 0$, the standard score of Y is $-Z$.

Proof

$E(Y) = a + bE(X)$ and $sd(Y) = |b| sd(X)$. Hence

$$\frac{Y - E(Y)}{sd(Y)} = \frac{b}{|b|} \frac{X - E(X)}{sd(X)} \quad (4.3.3)$$

As just noted, when $b > 0$, the variable $Y = a + bX$ is a location-scale transformation and often corresponds to a change of physical units. Since the standard score is dimensionless, it's reasonable that the standard scores of X and Y are the same. Here is another standardized measure of dispersion:

Suppose that X is a random variable with $E(X) \neq 0$. The *coefficient of variation* is the ratio of the standard deviation to the mean:

$$cv(X) = \frac{sd(X)}{E(X)} \quad (4.3.4)$$

The coefficient of variation is also dimensionless, and is sometimes used to compare variability for random variables with different means. We will learn how to compute the variance of the sum of two random variables in the section on covariance.

Chebyshev's Inequality

Chebyshev's inequality (named after Pafnuty Chebyshev) gives an upper bound on the probability that a random variable will be more than a specified distance from its mean. This is often useful in applied problems where the distribution is unknown, but the mean and variance are known (at least approximately). In the following two results, suppose that X is a real-valued random variable with mean $\mu = E(X) \in \mathbb{R}$ and standard deviation $\sigma = sd(X) \in (0, \infty)$.

Chebyshev's inequality 1.

$$\mathbb{P}(|X - \mu| \geq t) \leq \frac{\sigma^2}{t^2}, \quad t > 0 \quad (4.3.5)$$

Proof

Figure 4.3.3: Chebyshev's inequality

Here's an alternate version, with the distance in terms of standard deviation.

Chebyshev's inequality 2.

$$\mathbb{P}(|X - \mu| \geq k\sigma) \leq \frac{1}{k^2}, \quad k > 0 \quad (4.3.6)$$

Proof

Let $t = k\sigma$ in the first version of [Chebyshev's inequality](#).

The usefulness of the Chebyshev inequality comes from the fact that it holds for any distribution (assuming only that the mean and variance exist). The tradeoff is that for many specific distributions, the Chebyshev bound is rather crude. Note in particular that the [first inequality](#) is useless when $t \leq \sigma$, and the [second inequality](#) is useless when $k \leq 1$, since 1 is an upper bound for the probability of any event. On the other hand, it's easy to construct a distribution for which [Chebyshev's inequality](#) is sharp for a specified value of $t \in (0, \infty)$. Such a distribution is given in an [exercise below](#).

Examples and Applications

As always, be sure to try the problems yourself before looking at the solutions and answers.

Indicator Variables

Suppose that X is an indicator variable with $p = \mathbb{P}(X = 1)$, where $p \in [0, 1]$. Then

1. $\mathbb{E}(X) = p$
2. $\text{var}(X) = p(1 - p)$

Proof

1. We proved this in the section on basic properties, although the result is so simple that we can do it again: $\mathbb{E}(X) = 1 \cdot p + 0 \cdot (1 - p) = p$.
2. Note that $X^2 = X$ since X only takes values 0 and 1. Hence $\mathbb{E}(X^2) = p$ and therefore $\text{var}(X) = p - p^2 = p(1 - p)$.

The graph of $\text{var}(X)$ as a function of p is a parabola, opening downward, with roots at 0 and 1. Thus the minimum value of $\text{var}(X)$ is 0, and occurs when $p = 0$ and $p = 1$ (when X is deterministic, of course). The maximum value is $\frac{1}{4}$ and occurs when $p = \frac{1}{2}$.

Figure 4.3.4: The variance of an indicator variable as a function of p .

Uniform Distributions

Discrete uniform distributions are widely used in combinatorial probability, and model a point chosen *at random* from a finite set. The mean and variance have simple forms for the discrete uniform distribution on a set of evenly spaced points (sometimes referred to as a *discrete interval*):

Suppose that X has the discrete uniform distribution on $\{a, a + h, \dots, a + (n - 1)h\}$ where $a \in \mathbb{R}$, $h \in (0, \infty)$, and $n \in \mathbb{N}_+$. Let $b = a + (n - 1)h$, the right endpoint. Then

1. $\mathbb{E}(X) = \frac{1}{2}(a + b)$.
2. $\text{var}(X) = \frac{1}{12}(b - a)(b - a + 2h)$.

Proof

1. We proved this in the section on basic properties. Here it is again, using the formula for the sum of the first $n - 1$ positive integers:

$$\mathbb{E}(X) = \frac{1}{n} \sum_{i=0}^{n-1} (a + ih) = \frac{1}{n} \left(na + h \frac{(n-1)n}{2} \right) = a + \frac{(n-1)h}{2} = \frac{a+b}{2} \quad (4.3.7)$$

2. Note that

$$\mathbb{E}(X^2) = \frac{1}{n} \sum_{i=0}^{n-1} (a + ih)^2 = \frac{1}{n-1} \sum_{i=0}^{n-1} (a^2 + 2ahi + h^2 i^2) \quad (4.3.8)$$

Using the formulas for the sum of the first $n - 1$ positive integers, and the sum of the squares of the first $n - 1$ positive integers, we have

$$\mathbb{E}(X^2) = \frac{1}{n} \left[na^2 + 2ah \frac{(n-1)n}{2} + h^2 \frac{(n-1)n(2n-1)}{6} \right] \quad (4.3.9)$$

Using [computational formula](#) and simplifying gives the result.

Note that mean is simply the average of the endpoints, while the variance depends only on difference between the endpoints and the step size.

Open the special distribution simulator, and select the discrete uniform distribution. Vary the parameters and note the location and size of the mean \pm standard deviation bar in relation to the probability density function. For selected values of the parameters, run the simulation 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

Next, recall that the continuous uniform distribution on a bounded interval corresponds to selecting a point *at random* from the interval. Continuous uniform distributions arise in geometric probability and a variety of other applied problems.

Suppose that X has the continuous uniform distribution on the interval $[a, b]$ where $a, b \in \mathbb{R}$ with $a < b$. Then

1. $\mathbb{E}(X) = \frac{1}{2}(a + b)$
2. $\text{var}(X) = \frac{1}{12}(b - a)^2$

Proof

1. $\mathbb{E}(X) = \int_a^b x \frac{1}{b-a} dx = \frac{b^2 - a^2}{2(b-a)} = \frac{a+b}{2}$
2. $\mathbb{E}(X^2) = \int_a^b x^2 \frac{1}{b-a} dx = \frac{b^3 - a^3}{3(b-a)}$. The variance result then follows from (a), the [computational formula](#) and simple algebra.

Note that the mean is the midpoint of the interval and the variance depends only on the length of the interval. Compare this with the results in the discrete case.

Open the special distribution simulator, and select the continuous uniform distribution. This is the uniform distribution the interval $[a, a + w]$. Vary the parameters and note the location and size of the mean \pm standard deviation bar in relation to the probability density function. For selected values of the parameters, run the simulation 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

Dice

Recall that a *fair* die is one in which the faces are equally likely. In addition to fair dice, there are various types of crooked dice. Here are three:

- An *ace-six flat die* is a six-sided die in which faces 1 and 6 have probability $\frac{1}{4}$ each while faces 2, 3, 4, and 5 have probability $\frac{1}{8}$ each.
- A *two-five flat die* is a six-sided die in which faces 2 and 5 have probability $\frac{1}{4}$ each while faces 1, 3, 4, and 6 have probability $\frac{1}{8}$ each.
- A *three-four flat die* is a six-sided die in which faces 3 and 4 have probability $\frac{1}{4}$ each while faces 1, 2, 5, and 6 have probability $\frac{1}{8}$ each.

A flat die, as the name suggests, is a die that is not a cube, but rather is shorter in one of the three directions. The particular probabilities that we use ($\frac{1}{4}$ and $\frac{1}{8}$) are fictitious, but the essential property of a flat die is that the opposite faces on the shorter axis have slightly larger probabilities than the other four faces. Flat dice are sometimes used by gamblers to cheat. In the following problems, you will compute the mean and variance for each of the various types of dice. Be sure to compare the results.

A standard, fair die is thrown and the score X is recorded. Sketch the graph of the probability density function and compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{35}{12}$

An ace-six flat die is thrown and the score X is recorded. Sketch the graph of the probability density function and compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{15}{4}$

A two-five flat die is thrown and the score X is recorded. Sketch the graph of the probability density function and compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{11}{4}$

A three-four flat die is thrown and the score X is recorded. Sketch the graph of the probability density function and compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{9}{4}$

In the dice experiment, select one die. For each of the following cases, note the location and size of the mean \pm standard deviation bar in relation to the probability density function. Run the experiment 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

1. Fair die
2. Ace-six flat die
3. Two-five flat die
4. Three-four flat die

The Poisson Distribution

Recall that the *Poisson distribution* is a discrete distribution on \mathbb{N} with probability density function f given by

$$f(n) = e^{-a} \frac{a^n}{n!}, \quad n \in \mathbb{N} \quad (4.3.10)$$

where $a \in (0, \infty)$ is a parameter. The Poisson distribution is named after Simeon Poisson and is widely used to model the number of “random points” in a region of time or space; the parameter a is proportional to the size of the region. The Poisson distribution is studied in detail in the chapter on the Poisson Process.

Suppose that N has the Poisson distribution with parameter a . Then

1. $\mathbb{E}(N) = a$
2. $\text{var}(N) = a$

Proof

1. We did this computation in the previous section. Here it is again:

$$\mathbb{E}(N) = \sum_{n=0}^{\infty} n e^{-a} \frac{a^n}{n!} = e^{-a} \sum_{n=1}^{\infty} \frac{a^n}{(n-1)!} = e^{-a} a \sum_{n=1}^{\infty} \frac{a^{n-1}}{(n-1)!} = e^{-a} a e^a = a. \quad (4.3.11)$$

2. First we compute the *second factorial moment*:

$$\mathbb{E}[N(N-1)] = \sum_{n=1}^{\infty} n(n-1) e^{-a} \frac{a^n}{n!} = \sum_{n=2}^{\infty} e^{-a} \frac{a^n}{(n-2)!} = e^{-a} a^2 \sum_{n=2}^{\infty} \frac{a^{n-2}}{(n-2)!} = a^2 e^{-a} e^a = a^2 \quad (4.3.12)$$

Hence, $E(N^2) = \mathbb{E}[N(N-1)] + \mathbb{E}(N) = a^2 + a$ and so $\text{var}(N) = (a^2 + a) - a^2 = a$.

Thus, the parameter of the Poisson distribution is both the mean and the variance of the distribution.

In the Poisson experiment, the parameter is $a = rt$. Vary the parameter and note the size and location of the mean \pm standard deviation bar in relation to the probability density function. For selected values of the parameter, run the experiment 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

The Geometric Distribution

Recall that *Bernoulli trials* are independent trials each with two outcomes, which in the language of reliability, are called *success* and *failure*. The probability of success on each trial is $p \in [0, 1]$. A separate chapter on Bernoulli Trials explores this random process in more detail. It is named for Jacob Bernoulli. If $p \in (0, 1]$, the trial number N of the first success has the geometric distribution on \mathbb{N}_+ with success parameter p . The probability density function f of N is given by

$$f(n) = p(1-p)^{n-1}, \quad n \in \mathbb{N}_+ \quad (4.3.13)$$

Suppose that N has the geometric distribution on \mathbb{N}_+ with success parameter $p \in (0, 1]$. Then

1. $\mathbb{E}(N) = \frac{1}{p}$
2. $\text{var}(N) = \frac{1-p}{p^2}$

Proof

1. We proved this in the section on basic properties. Here it is again:

$$\mathbb{E}(N) = \sum_{n=1}^{\infty} n p (1-p)^{n-1} = -p \frac{d}{dp} \sum_{n=0}^{\infty} (1-p)^n = -p \frac{d}{dp} \frac{1}{p} = \frac{1}{p} \quad (4.3.14)$$

2. First we compute the *second factorial moment*:

$$\mathbb{E}[N(N-1)] = \sum_{n=2}^{\infty} n(n-1) (1-p)^{n-1} p = p(1-p) \frac{d^2}{dp^2} \sum_{n=0}^{\infty} (1-p)^n = p(1-p) \frac{d^2}{dp^2} \frac{1}{p} = p(1-p) \frac{2}{p^3} = \frac{2(1-p)}{p^2} \quad (4.3.15)$$

Hence $\mathbb{E}(N^2) = \mathbb{E}[N(N-1)] + \mathbb{E}(N) = 2/p^2 - 1/p$ and hence $\text{var}(X) = 2/p^2 - 1/p - 1/p^2 = 1/p^2 - 1/p$.

Note that the variance is 0 when $p = 1$, not surprising since X is deterministic in this case.

In the negative binomial experiment, set $k = 1$ to get the geometric distribution. Vary p with the scroll bar and note the size and location of the mean \pm standard deviation bar in relation to the probability density function. For selected values of p , run the experiment 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

Suppose that N has the geometric distribution with parameter $p = \frac{3}{4}$. Compute the true value and the Chebyshev bound for the probability that N is at least 2 standard deviations away from the mean.

Answer

1. $\frac{1}{16}$
2. $\frac{1}{4}$

The Exponential Distribution

Recall that the *exponential distribution* is a continuous distribution on $[0, \infty)$ with probability density function f given by

$$f(t) = re^{-rt}, \quad t \in [0, \infty) \quad (4.3.16)$$

where $r \in (0, \infty)$ is the *rate parameter*. This distribution is widely used to model failure times and other “arrival times”. The exponential distribution is studied in detail in the chapter on the Poisson Process.

Suppose that T has the exponential distribution with rate parameter r . Then

1. $\mathbb{E}(T) = \frac{1}{r}$.
2. $\text{var}(T) = \frac{1}{r^2}$.

Proof

1. We proved this in the section on basic properties. Here it is again, using integration by parts:

$$\mathbb{E}(T) = \int_0^\infty t r e^{-rt} dt = -t e^{-rt} \Big|_0^\infty + \int_0^\infty e^{-rt} dt = 0 - \frac{1}{r} e^{-rt} \Big|_0^\infty = \frac{1}{r} \quad (4.3.17)$$

2. Integrating by parts again and using (a), we have

$$\mathbb{E}(T^2) = \int_0^\infty t^2 r e^{-rt} dt = -t^2 e^{-rt} \Big|_0^\infty + \int_0^\infty 2t e^{-rt} dt = 0 + \frac{2}{r^2} \quad (4.3.18)$$

$$\text{Hence } \text{var}(T) = \frac{2}{r^2} - \frac{1}{r^2} = \frac{1}{r^2}$$

Thus, for the exponential distribution, the mean and standard deviation are the same.

In the gamma experiment, set $k = 1$ to get the exponential distribution. Vary r with the scroll bar and note the size and location of the mean \pm standard deviation bar in relation to the probability density function. For selected values of r , run the experiment 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

Suppose that X has the exponential distribution with rate parameter $r > 0$. Compute the true value and the Chebyshev bound for the probability that X is at least k standard deviations away from the mean.

Answer

1. $e^{-(k+1)}$
2. $\frac{1}{k^2}$

The Pareto Distribution

Recall that the *Pareto distribution* is a continuous distribution on $[1, \infty)$ with probability density function f given by

$$f(x) = \frac{a}{x^{a+1}}, \quad x \in [1, \infty) \quad (4.3.19)$$

where $a \in (0, \infty)$ is a parameter. The Pareto distribution is named for Vilfredo Pareto. It is a heavy-tailed distribution that is widely used to model financial variables such as income. The Pareto distribution is studied in detail in the chapter on Special Distributions.

Suppose that X has the Pareto distribution with shape parameter a . Then

1. $\mathbb{E}(X) = \infty$ if $0 < a \leq 1$ and $\mathbb{E}(X) = \frac{a}{a-1}$ if $1 < a < \infty$

2. $\text{var}(X)$ is undefined if $0 < a \leq 1$, $\text{var}(X) = \infty$ if $1 < a \leq 2$, and $\text{var}(X) = \frac{a}{(a-1)^2(a-2)}$ if $2 < a < \infty$

Proof

1. We proved this in the section on basic properties. Here it is again:

$$\mathbb{E}(X) = \int_1^\infty x \frac{a}{x^{a+1}} dx = \int_1^\infty \frac{a}{x^a} dx = \frac{a}{-a+1} x^{-a+1} \Big|_1^\infty = \begin{cases} \infty, & 0 < a < 1 \\ \frac{a}{a-1}, & a > 1 \end{cases} \quad (4.3.20)$$

When $a = 1$, $\mathbb{E}(X) = \int_1^\infty \frac{1}{x} dx = \ln x \Big|_1^\infty = \infty$

2. If $0 < a \leq 1$ then $\mathbb{E}(X) = \infty$ and so $\text{var}(X)$ is undefined. On the other hand,

$$\mathbb{E}(X^2) = \int_1^\infty x^2 \frac{a}{x^{a+1}} dx = \int_1^\infty \frac{a}{x^{a-1}} dx = ax^{-a+2} \Big|_1^\infty = \begin{cases} \infty, & 0 < a < 2 \\ \frac{a}{a-2}, & a > 2 \end{cases} \quad (4.3.21)$$

When $a = 2$, $\mathbb{E}(X^2) = \int_1^\infty \frac{2}{x} dx = \infty$. Hence $\text{var}(X) = \infty$ if $1 < a \leq 2$ and $\text{var}(X) = \frac{a}{a-2} - \left(\frac{a}{a-1}\right)^2$ if $a > 2$.

In the special distribution simulator, select the Pareto distribution. Vary a with the scroll bar and note the size and location of the mean \pm standard deviation bar. For each of the following values of a , run the experiment 1000 times and note the behavior of the empirical mean and standard deviation.

1. $a = 1$
2. $a = 2$
3. $a = 3$

The Normal Distribution

Recall that the *standard normal distribution* is a continuous distribution on \mathbb{R} with probability density function ϕ given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}, \quad z \in \mathbb{R} \quad (4.3.22)$$

Normal distributions are widely used to model physical measurements subject to small, random errors and are studied in detail in the chapter on Special Distributions.

Suppose that Z has the standard normal distribution. Then

1. $\mathbb{E}(Z) = 0$
2. $\text{var}(Z) = 1$

Proof

1. We proved this in the section on basic properties. Here it is again:

$$\mathbb{E}(Z) = \int_{-\infty}^\infty z \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} dz = -\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} \Big|_{-\infty}^\infty = 0 - 0 \quad (4.3.23)$$

2. From (a), $\text{var}(Z) = \mathbb{E}(Z^2) = \int_{-\infty}^\infty z^2 \phi(z) dz$. Integrate by parts with $u = z$ and $dv = z\phi(z) dz$. Thus, $du = dz$ and $v = -\phi(z)$. Hence

$$\text{var}(Z) = -z\phi(z) \Big|_{-\infty}^\infty + \int_{-\infty}^\infty \phi(z) dz = 0 + 1 \quad (4.3.24)$$

More generally, for $\mu \in \mathbb{R}$ and $\sigma \in (0, \infty)$, recall that the normal distribution with *location parameter* μ and *scale parameter* σ is a continuous distribution on \mathbb{R} with probability density function f given by

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right], \quad x \in \mathbb{R} \quad (4.3.25)$$

Moreover, if Z has the standard normal distribution, then $X = \mu + \sigma Z$ has the normal distribution with location parameter μ and scale parameter σ . As the notation suggests, the location parameter is the mean of the distribution and the scale parameter is the standard deviation.

Suppose that X has the normal distribution with location parameter μ and scale parameter σ . Then

1. $\mathbb{E}(X) = \mu$
2. $\text{var}(X) = \sigma^2$

Proof

We could use the probability density function, of course, but it's much better to use the representation of X in terms of the standard normal variable Z , and use properties of expected value and variance.

1. $\mathbb{E}(X) = \mu + \sigma \mathbb{E}(Z) = \mu + 0 = \mu$
2. $\text{var}(X) = \sigma^2 \text{var}(Z) = \sigma^2 \cdot 1 = \sigma^2$.

So to summarize, if X has a normal distribution, then its standard score Z has the standard normal distribution.

In the special distribution simulator, select the normal distribution. Vary the parameters and note the shape and location of the mean \pm standard deviation bar in relation to the probability density function. For selected parameter values, run the experiment 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

Beta Distributions

The distributions in this subsection belong to the family of *beta distributions*, which are widely used to model random proportions and probabilities. The beta distribution is studied in detail in the chapter on Special Distributions.

Suppose that X has a beta distribution with probability density function f . In each case below, graph f below and compute the mean and variance.

1. $f(x) = 6x(1-x)$ for $x \in [0, 1]$
2. $f(x) = 12x^2(1-x)$ for $x \in [0, 1]$
3. $f(x) = 12x(1-x)^2$ for $x \in [0, 1]$

Answer

1. $\mathbb{E}(X) = \frac{1}{2}$, $\text{var}(X) = \frac{1}{20}$
2. $\mathbb{E}(X) = \frac{3}{5}$, $\text{var}(X) = \frac{1}{25}$
3. $\mathbb{E}(X) = \frac{2}{6}$, $\text{var}(X) = \frac{1}{25}$

In the special distribution simulator, select the beta distribution. The parameter values below give the distributions in the previous exercise. In each case, note the location and size of the mean \pm standard deviation bar. Run the experiment 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

1. $a = 2$, $b = 2$
2. $a = 3$, $b = 2$
3. $a = 2$, $b = 3$

Suppose that a sphere has a random radius R with probability density function f given by $f(r) = 12r^2(1-r)$ for $r \in [0, 1]$. Find the mean and standard deviation of each of the following:

1. The circumference $C = 2\pi R$
2. The surface area $A = 4\pi R^2$
3. The volume $V = \frac{4}{3}\pi R^3$

Answer

1. $\frac{6}{5}\pi$, $\frac{2}{5}\pi$
2. $\frac{8}{5}\pi$, $\frac{2}{5}\sqrt{\frac{38}{7}}\pi$
3. $\frac{8}{21}\pi$, $\frac{8}{3}\sqrt{\frac{19}{1470}}\pi$

Suppose that X has probability density function f given by $f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$ for $x \in (0, 1)$. Find

1. $\mathbb{E}(X)$
2. $\text{var}(X)$

Answer

1. $\frac{1}{2}$
2. $\frac{1}{8}$

The particular beta distribution in the last exercise is also known as the (standard) *arcsine distribution*. It governs the last time that the Brownian motion process hits 0 during the time interval $[0, 1]$. The arcsine distribution is studied in more generality in the chapter on Special Distributions.

Open the Brownian motion experiment and select the last zero. Note the location and size of the mean \pm standard deviation bar in relation to the probability density function. Run the simulation 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

Suppose that the grades on a test are described by the random variable $Y = 100X$ where X has the beta distribution with probability density function f given by $f(x) = 12x(1-x)^2$ for $x \in [0, 1]$. The grades are generally low, so the teacher decides to “curve” the grades using the transformation $Z = 10\sqrt{Y} = 100\sqrt{X}$. Find the mean and standard deviation of each of the following variables:

1. X
2. Y
3. Z

Answer

1. $\mathbb{E}(X) = \frac{2}{5}$, $\text{sd}(X) = \frac{1}{5}$
2. $\mathbb{E}(Y) = 40$, $\text{sd}(Y) = 20$
3. $\mathbb{E}(Z) = 60.95$, $\text{sd}(Z) = 16.88$

Exercises on Basic Properties

Suppose that X is a real-valued random variable with $\mathbb{E}(X) = 5$ and $\text{var}(X) = 4$. Find each of the following:

1. $\text{var}(3X - 2)$
2. $\mathbb{E}(X^2)$

Answer

1. 36
2. 29

Suppose that X is a real-valued random variable with $\mathbb{E}(X) = 2$ and $\mathbb{E}[X(X-1)] = 8$. Find each of the following:

1. $\mathbb{E}(X^2)$
2. $\text{var}(X)$

Answer

1. 10
2. 6

The expected value $\mathbb{E}[X(X-1)]$ is an example of a *factorial moment*.

Suppose that X_1 and X_2 are independent, real-valued random variables with $\mathbb{E}(X_i) = \mu_i$ and $\text{var}(X_i) = \sigma_i^2$ for $i \in \{1, 2\}$. Then

1. $\mathbb{E}(X_1 X_2) = \mu_1 \mu_2$
2. $\text{var}(X_1 X_2) = \sigma_1^2 \sigma_2^2 + \sigma_1^2 \mu_2^2 + \sigma_2^2 \mu_1^2$

Proof

1. This is an important, basic result that was proved in the section on basic properties.
2. Since X_1^2 and X_2^2 are also independent, we have $\mathbb{E}(X_1^2 X_2^2) = \mathbb{E}(X_1^2) \mathbb{E}(X_2^2) = (\sigma_1^2 + \mu_1^2)(\sigma_2^2 + \mu_2^2)$. The result then follows from the [computational formula](#) and algebra.

Marilyn Vos Savant has an IQ of 228. Assuming that the distribution of IQ scores has mean 100 and standard deviation 15, find Marilyn's standard score.

Answer

$$z = 8.53$$

Fix $t \in (0, \infty)$. Suppose that X is the discrete random variable with probability density function defined by $\mathbb{P}(X = t) = \mathbb{P}(X = -t) = p$, $\mathbb{P}(X = 0) = 1 - 2p$, where $p \in (0, \frac{1}{2})$. Then equality holds in [Chebyshev's inequality](#) at t .

Proof

Note that $\mathbb{E}(X) = 0$ and $\text{var}(X) = \mathbb{E}(X^2) = 2pt^2$. So $\mathbb{P}(|X| \geq t) = 2p$ and $\sigma^2/t^2 = 2p$.

This page titled [4.3: Variance](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist \(Random Services\)](#) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

4.4: Skewness and Kurtosis

As usual, our starting point is a random experiment, modeled by a probability space (Ω, \mathcal{F}, P) . So to review, Ω is the set of outcomes, \mathcal{F} the collection of events, and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) . Suppose that X is a real-valued random variable for the experiment. Recall that the mean of X is a measure of the center of the distribution of X . Furthermore, the variance of X is the second moment of X about the mean, and measures the spread of the distribution of X about the mean. The third and fourth moments of X about the mean also measure interesting (but more subtle) features of the distribution. The third moment measures *skewness*, the lack of symmetry, while the fourth moment measures *kurtosis*, roughly a measure of the fatness in the tails. The actual numerical measures of these characteristics are standardized to eliminate the physical units, by dividing by an appropriate power of the standard deviation. As usual, we assume that all expected values given below exist, and we will let $\mu = \mathbb{E}(X)$ and $\sigma^2 = \text{var}(X)$. We assume that $\sigma > 0$, so that the random variable is really random.

Basic Theory

Skewness

The *skewness* of X is the third moment of the standard score of X :

$$\text{skew}(X) = \mathbb{E} \left[\left(\frac{X - \mu}{\sigma} \right)^3 \right] \quad (4.4.1)$$

The distribution of X is said to be *positively skewed*, *negatively skewed* or *unskewed* depending on whether $\text{skew}(X)$ is positive, negative, or 0.

In the unimodal case, if the distribution is positively skewed then the probability density function has a long tail to the right, and if the distribution is negatively skewed then the probability density function has a long tail to the left. A symmetric distribution is unskewed.

Suppose that the distribution of X is symmetric about a . Then

1. $\mathbb{E}(X) = a$
2. $\text{skew}(X) = 0$.

Proof

By assumption, the distribution of $a - X$ is the same as the distribution of $X - a$. We proved part (a) in the section on properties of expected value. Thus, $\text{skew}(X) = \mathbb{E}[(X - a)^3] / \sigma^3$. But by symmetry and linearity, $\mathbb{E}[(X - a)^3] = \mathbb{E}[(a - X)^3] = -\mathbb{E}[(X - a)^3]$, so it follows that $\mathbb{E}[(X - a)^3] = 0$.

The converse is not true—a non-symmetric distribution can have skewness 0. Examples are given in Exercises (30) and (31) below.

$\text{skew}(X)$ can be expressed in terms of the first three moments of X .

$$\text{skew}(X) = \frac{\mathbb{E}(X^3) - 3\mu\mathbb{E}(X^2) + 2\mu^3}{\sigma^3} = \frac{\mathbb{E}(X^3) - 3\mu\sigma^2 - \mu^3}{\sigma^3} \quad (4.4.2)$$

Proof

Note that $(X - \mu)^3 = X^3 - 3X^2\mu + 3X\mu^2 - \mu^3$. From the linearity of expected value we have

$$\mathbb{E}[(X - \mu)^3] = \mathbb{E}(X^3) - 3\mu\mathbb{E}(X^2) + 3\mu^2\mathbb{E}(X) - \mu^3 = \mathbb{E}(X^3) - 3\mu\mathbb{E}(X^2) + 2\mu^3 \quad (4.4.3)$$

The second expression follows from substituting $\mathbb{E}(X^2) = \sigma^2 + \mu^2$.

Since skewness is defined in terms of an odd power of the standard score, it's invariant under a linear transformation with positive slope (a location-scale transformation of the distribution). On the other hand, if the slope is negative, skewness changes sign.

Suppose that $a \in \mathbb{R}$ and $b \in \mathbb{R} \setminus \{0\}$. Then

1. $\text{skew}(a + bX) = \text{skew}(X)$ if $b > 0$
2. $\text{skew}(a + bX) = -\text{skew}(X)$ if $b < 0$

Proof

Let $Z = (X - \mu)/\sigma$, the standard score of X . Recall from the section on variance that the standard score of $a + bX$ is Z if $b > 0$ and is $-Z$ if $b < 0$.

Recall that location-scale transformations often arise when physical units are changed, such as inches to centimeters, or degrees Fahrenheit to degrees Celsius.

Kurtosis

The *kurtosis* of X is the fourth moment of the standard score:

$$\text{kurt}(X) = \mathbb{E} \left[\left(\frac{X - \mu}{\sigma} \right)^4 \right] \quad (4.4.4)$$

Kurtosis comes from the Greek word for *bulging*. Kurtosis is always positive, since we have assumed that $\sigma > 0$ (the random variable really is random), and therefore $\mathbb{P}(X \neq \mu) > 0$. In the unimodal case, the probability density function of a distribution with large kurtosis has fatter tails, compared with the probability density function of a distribution with smaller kurtosis.

$\text{kurt}(X)$ can be expressed in terms of the first four moments of X .

$$\text{kurt}(X) = \frac{\mathbb{E}(X^4) - 4\mu\mathbb{E}(X^3) + 6\mu^2\mathbb{E}(X^2) - 3\mu^4}{\sigma^4} = \frac{\mathbb{E}(X^4) - 4\mu\mathbb{E}(X^3) + 6\mu^2\sigma^2 + 3\mu^4}{\sigma^4} \quad (4.4.5)$$

Proof

Note that $(X - \mu)^4 = X^4 - 4X^3\mu + 6X^2\mu^2 - 4X\mu^3 + \mu^4$. From linearity of expected value, we have

$$\mathbb{E}[(X - \mu)^4] = \mathbb{E}(X^4) - 4\mu\mathbb{E}(X^3) + 6\mu^2\mathbb{E}(X^2) - 4\mu^3\mathbb{E}(X) + \mu^4 = \mathbb{E}(X^4) - 4\mu\mathbb{E}(X^3) + 6\mu^2\mathbb{E}(X^2) - 3\mu^4 \quad (4.4.6)$$

The second expression follows from the substitution $\mathbb{E}(X^2) = \sigma^2 + \mu^2$.

Since kurtosis is defined in terms of an even power of the standard score, it's invariant under linear transformations.

Suppose that $a \in \mathbb{R}$ and $b \in \mathbb{R} \setminus \{0\}$. Then $\text{kurt}(a + bX) = \text{kurt}(X)$.

Proof

As before, let $Z = (X - \mu)/\sigma$ denote the standard score of X . Then the standard score of $a + bX$ is Z if $b > 0$ and is $-Z$ if $b < 0$.

We will show in [below](#) that the kurtosis of the standard normal distribution is 3. Using the standard normal distribution as a benchmark, the *excess kurtosis* of a random variable X is defined to be $\text{kurt}(X) - 3$. Some authors use the term *kurtosis* to mean what we have defined as *excess kurtosis*.

Computational Exercises

As always, be sure to try the exercises yourself before expanding the solutions and answers in the text.

Indicator Variables

Recall that an *indicator random variable* is one that just takes the values 0 and 1. Indicator variables are the building blocks of many counting random variables. The corresponding distribution is known as the *Bernoulli distribution*, named for Jacob Bernoulli.

Suppose that X is an indicator variable with $\mathbb{P}(X = 1) = p$ where $p \in (0, 1)$. Then

1. $\mathbb{E}(X) = p$
2. $\text{var}(X) = p(1 - p)$
3. $\text{skew}(X) = \frac{1 - 2p}{\sqrt{p(1 - p)}}$
4. $\text{kurt}(X) = \frac{1 - 3p + 3p^2}{p(1 - p)}$

Proof

Parts (a) and (b) have been derived before. All four parts follow easily from the fact that $X^n = X$ and hence $\mathbb{E}(X^n) = p$ for $n \in \mathbb{N}_+$.

Open the binomial coin experiment and set $n = 1$ to get an indicator variable. Vary p and note the change in the shape of the probability density function.

Dice

Recall that a *fair* die is one in which the faces are equally likely. In addition to fair dice, there are various types of crooked dice. Here are three:

- An *ace-six flat die* is a six-sided die in which faces 1 and 6 have probability $\frac{1}{4}$ each while faces 2, 3, 4, and 5 have probability $\frac{1}{8}$ each.
- A *two-five flat die* is a six-sided die in which faces 2 and 5 have probability $\frac{1}{4}$ each while faces 1, 3, 4, and 6 have probability $\frac{1}{8}$ each.
- A *three-four flat die* is a six-sided die in which faces 3 and 4 have probability $\frac{1}{4}$ each while faces 1, 2, 5, and 6 have probability $\frac{1}{8}$ each.

A flat die, as the name suggests, is a die that is not a cube, but rather is shorter in one of the three directions. The particular probabilities that we use ($\frac{1}{4}$ and $\frac{1}{8}$) are fictitious, but the essential property of a flat die is that the opposite faces on the shorter axis have slightly larger probabilities than the other four faces. Flat dice are sometimes used by gamblers to cheat.

A standard, fair die is thrown and the score X is recorded. Compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{35}{12}$
3. 0
4. $\frac{303}{175}$

An ace-six flat die is thrown and the score X is recorded. Compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{15}{4}$
3. 0
4. $\frac{37}{25}$

A two-five flat die is thrown and the score X is recorded. Compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{11}{4}$
3. 0
4. $\frac{197}{121}$

A three-four flat die is thrown and the score X is recorded. Compute each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$

3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{7}{2}$
2. $\frac{9}{4}$
3. 0
4. $\frac{59}{27}$

All four die distributions above have the same mean $\frac{7}{2}$ and are symmetric (and hence have skewness 0), but differ in variance and kurtosis.

Open the dice experiment and set $n = 1$ to get a single die. Select each of the following, and note the shape of the probability density function in comparison with the computational results above. In each case, run the experiment 1000 times and compare the empirical density function to the probability density function.

1. fair
2. ace-six flat
3. two-five flat
4. three-four flat

Uniform Distributions

Recall that the continuous uniform distribution on a bounded interval corresponds to selecting a point *at random* from the interval. Continuous uniform distributions arise in geometric probability and a variety of other applied problems.

Suppose that X has uniform distribution on the interval $[a, b]$, where $a, b \in \mathbb{R}$ and $a < b$. Then

1. $\mathbb{E}(X) = \frac{1}{2}(a + b)$
2. $\text{var}(X) = \frac{1}{12}(b - a)^2$
3. $\text{skew}(X) = 0$
4. $\text{kurt}(X) = \frac{9}{5}$

Proof

Parts (a) and (b) we have seen before. For parts (c) and (d), recall that $X = a + (b - a)U$ where U has the uniform distribution on $[0, 1]$ (the *standard uniform distribution*). Hence it follows from the formulas for [skewness](#) and [kurtosis](#) under linear transformations that $\text{skew}(X) = \text{skew}(U)$ and $\text{kurt}(X) = \text{kurt}(U)$. Since $\mathbb{E}(U^n) = 1/(n + 1)$ for $n \in \mathbb{N}_+$, it's easy to compute the skewness and kurtosis of U from the computational formulas [skewness](#) and [kurtosis](#). Of course, the fact that $\text{skew}(X) = 0$ also follows trivially from the symmetry of the distribution of X about the mean.

Open the special distribution simulator, and select the continuous uniform distribution. Vary the parameters and note the shape of the probability density function in comparison with the moment results in the last exercise. For selected values of the parameter, run the simulation 1000 times and compare the empirical density function to the probability density function.

The Exponential Distribution

Recall that the *exponential distribution* is a continuous distribution on $[0, \infty)$ with probability density function f given by

$$f(t) = re^{-rt}, \quad t \in [0, \infty) \quad (4.4.7)$$

where $r \in (0, \infty)$ is the *rate parameter*. This distribution is widely used to model failure times and other “arrival times”. The exponential distribution is studied in detail in the chapter on the Poisson Process.

Suppose that X has the exponential distribution with rate parameter $r > 0$. Then

1. $\mathbb{E}(X) = \frac{1}{r}$
2. $\text{var}(X) = \frac{1}{r^2}$
3. $\text{skew}(X) = 2$
4. $\text{kurt}(X) = 9$

Proof

These results follow from the computational formulas for [skewness](#) and [kurtosis](#) and the general moment formula $\mathbb{E}(X^n) = n!/r^n$ for $n \in \mathbb{N}$.

Note that the skewness and kurtosis do not depend on the rate parameter r . That's because $1/r$ is a scale parameter for the exponential distribution

Open the gamma experiment and set $n = 1$ to get the exponential distribution. Vary the rate parameter and note the shape of the probability density function in comparison to the moment results in the last exercise. For selected values of the parameter, run the experiment 1000 times and compare the empirical density function to the true probability density function.

Pareto Distribution

Recall that the *Pareto distribution* is a continuous distribution on $[1, \infty)$ with probability density function f given by

$$f(x) = \frac{a}{x^{a+1}}, \quad x \in [1, \infty) \quad (4.4.8)$$

where $a \in (0, \infty)$ is a parameter. The Pareto distribution is named for Vilfredo Pareto. It is a heavy-tailed distribution that is widely used to model financial variables such as income. The Pareto distribution is studied in detail in the chapter on Special Distributions.

Suppose that X has the Pareto distribution with shape parameter $a > 0$. Then

1. $\mathbb{E}(X) = \frac{a}{a-1}$ if $a > 1$
2. $\text{var}(X) = \frac{a}{(a-1)^2(a-2)}$ if $a > 2$
3. $\text{skew}(X) = \frac{2(1+a)}{a-3} \sqrt{1 - \frac{2}{a}}$ if $a > 3$
4. $\text{kurt}(X) = \frac{3(a-2)(3a^2+a+2)}{a(a-3)(a-4)}$ if $a > 4$

Proof

These results follow from the standard computational formulas for [skewness](#) and [kurtosis](#) and the general moment formula $\mathbb{E}(X^n) = \frac{a}{a-n}$ if $n \in \mathbb{N}$ and $n < a$.

Open the special distribution simulator and select the Pareto distribution. Vary the shape parameter and note the shape of the probability density function in comparison to the moment results in the last exercise. For selected values of the parameter, run the experiment 1000 times and compare the empirical density function to the true probability density function.

The Normal Distribution

Recall that the *standard normal distribution* is a continuous distribution on \mathbb{R} with probability density function ϕ given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}, \quad z \in \mathbb{R} \quad (4.4.9)$$

Normal distributions are widely used to model physical measurements subject to small, random errors and are studied in detail in the chapter on Special Distributions.

Suppose that Z has the standard normal distribution. Then

1. $\mathbb{E}(Z) = 0$
2. $\text{var}(Z) = 1$
3. $\text{skew}(Z) = 0$
4. $\text{kurt}(Z) = 3$

Proof

Parts (a) and (b) were derived in the previous sections on expected value and variance. Part (c) follows from symmetry. For part (d), recall that $\mathbb{E}(Z^4) = 3\mathbb{E}(Z^2) = 3$.

More generally, for $\mu \in \mathbb{R}$ and $\sigma \in (0, \infty)$, recall that the normal distribution with mean μ and standard deviation σ is a continuous distribution on \mathbb{R} with probability density function f given by

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right], \quad x \in \mathbb{R} \quad (4.4.10)$$

However, we also know that μ and σ are location and scale parameters, respectively. That is, if Z has the standard normal distribution then $X = \mu + \sigma Z$ has the normal distribution with mean μ and standard deviation σ .

If X has the normal distribution with mean $\mu \in \mathbb{R}$ and standard deviation $\sigma \in (0, \infty)$, then

1. $\text{skew}(X) = 0$
2. $\text{kurt}(X) = 3$

Proof

The results follow immediately from the formulas for [skewness](#) and [kurtosis](#) under linear transformations and the previous result.

Open the special distribution simulator and select the normal distribution. Vary the parameters and note the shape of the probability density function in comparison to the moment results in the last exercise. For selected values of the parameters, run the experiment 1000 times and compare the empirical density function to the true probability density function.

The Beta Distribution

The distributions in this subsection belong to the family of *beta distributions*, which are continuous distributions on $[0, 1]$ widely used to model random proportions and probabilities. The beta distribution is studied in detail in the chapter on Special Distributions.

Suppose that X has probability density function f given by $f(x) = 6x(1 - x)$ for $x \in [0, 1]$. Find each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{1}{2}$
2. $\frac{1}{20}$
3. 0
4. $\frac{15}{7}$

Suppose that X has probability density function f given by $f(x) = 12x^2(1 - x)$ for $x \in [0, 1]$. Find each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{3}{5}$
2. $\frac{1}{25}$
3. $-\frac{2}{7}$
4. $\frac{33}{14}$

Suppose that X has probability density function f given by $f(x) = 12x(1 - x)^2$ for $x \in [0, 1]$. Find each of the following:

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{2}{5}$
2. $\frac{1}{25}$
3. $\frac{2}{7}$
4. $\frac{33}{14}$

Open the special distribution simulator and select the beta distribution. Select the parameter values below to get the distributions in the last three exercises. In each case, note the shape of the probability density function in relation to the calculated moment results. Run the simulation 1000 times and compare the empirical density function to the probability density function.

1. $a = 2, b = 2$
2. $a = 3, b = 2$
3. $a = 2, b = 3$

Suppose that X has probability density function f given by $f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$ for $x \in (0, 1)$. Find

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. $\frac{1}{2}$
2. $\frac{1}{8}$
3. 0
4. 96

The particular beta distribution in the last exercise is also known as the (standard) *arcsine distribution*. It governs the last time that the Brownian motion process hits 0 during the time interval $[0, 1]$. The arcsine distribution is studied in more generality in the chapter on Special Distributions.

Open the Brownian motion experiment and select the last zero. Note the shape of the probability density function in relation to the moment results in the last exercise. Run the simulation 1000 times and compare the empirical density function to the probability density function.

Counterexamples

The following exercise gives a simple example of a discrete distribution that is not symmetric but has skewness 0.

Suppose that X is a discrete random variable with probability density function f given by $f(-3) = \frac{1}{10}, f(-1) = \frac{1}{2}, f(2) = \frac{2}{5}$. Find each of the following and then show that the distribution of X is not symmetric.

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Answer

1. 0
2. 3
3. 0
4. $\frac{5}{3}$

The PDF f is clearly not symmetric about 0, and the mean is the only possible point of symmetry.

The following exercise gives a more complicated continuous distribution that is not symmetric but has skewness 0. It is one of a collection of distributions constructed by [Erik Meijer](#).

Suppose that U , V , and I are independent random variables, and that U is normally distributed with mean $\mu = -2$ and variance $\sigma^2 = 1$, V is normally distributed with mean $\nu = 1$ and variance $\tau^2 = 2$, and I is an indicator variable with $\mathbb{P}(I = 1) = p = \frac{1}{3}$. Let $X = IU + (1 - I)V$. Find each of the following and then show that the distribution of X is not symmetric.

1. $\mathbb{E}(X)$
2. $\text{var}(X)$
3. $\text{skew}(X)$
4. $\text{kurt}(X)$

Solution

The distribution of X is a *mixture* of normal distributions. The PDF is $f = pg + (1 - p)h$ where g is the normal PDF of U and h is the normal PDF of V . However, it's best to work with the random variables. For $n \in \mathbb{N}_+$, note that $I^n = I$ and $(1 - I)^n = 1 - I$ and note also that the random variable $I(1 - I)$ just takes the value 0. It follows that

$$X^n = IU^n + (1 - I)V^n, \quad n \in \mathbb{N}_+ \quad (4.4.11)$$

So now, using standard results for the normal distribution,

1. $\mathbb{E}(X) = p\mu + (1 - p)\nu = 0$.
2. $\text{var}(X) = \mathbb{E}(X^2) = p(\sigma^2 + \mu^2) + (1 - p)(\tau^2 + \nu^2) = \frac{11}{3}$
3. $\mathbb{E}(X^3) = p(3\mu\sigma^2 + \mu^3) + (1 - p)(3\nu\tau^2 + \nu^3) = 0$ so $\text{skew}(X) = 0$
4. $\mathbb{E}(X^4) = p(3\sigma^4 + 6\sigma^2\mu^2 + \mu^4) + (1 - p)(3\tau^4 + 6\tau^2\nu^2 + \nu^4) = 31$ so $\text{kurt}(X) = \frac{279}{121} \approx 2.306$

The graph of the PDF f of X is given below. Note that f is not symmetric about 0. (Again, the mean is the only possible point of symmetry.)

The PDF of X

This page titled [4.4: Skewness and Kurtosis](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist \(Random Services\)](#) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

4.5: Covariance and Correlation

Recall that by taking the expected value of various transformations of a random variable, we can measure many interesting characteristics of the distribution of the variable. In this section, we will study an expected value that measures a special type of relationship between two real-valued variables. This relationship is very important both in probability and statistics.

Basic Theory

Definitions

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Unless otherwise noted, we assume that all expected values mentioned in this section exist. Suppose now that X and Y are real-valued random variables for the experiment (that is, defined on the probability space) with means $\mathbb{E}(X)$, $\mathbb{E}(Y)$ and variances $\text{var}(X)$, $\text{var}(Y)$, respectively.

The *covariance* of (X, Y) is defined by

$$\text{cov}(X, Y) = \mathbb{E}([X - \mathbb{E}(X)][Y - \mathbb{E}(Y)]) \quad (4.5.1)$$

and, assuming the variances are positive, the *correlation* of (X, Y) is defined by

$$\text{cor}(X, Y) = \frac{\text{cov}(X, Y)}{\text{sd}(X)\text{sd}(Y)} \quad (4.5.2)$$

1. If $\text{cov}(X, Y) > 0$ then X and Y are *positively correlated*.
2. If $\text{cov}(X, Y) < 0$ then X and Y are *negatively correlated*.
3. If $\text{cov}(X, Y) = 0$ then X and Y are *uncorrelated*.

Correlation is a scaled version of covariance; note that the two parameters always have the same sign (positive, negative, or 0). Note also that correlation is dimensionless, since the numerator and denominator have the same physical units, namely the product of the units of X and Y .

As these terms suggest, covariance and correlation measure a certain kind of dependence between the variables. One of our goals is a deeper understanding of this dependence. As a start, note that $(\mathbb{E}(X), \mathbb{E}(Y))$ is the center of the joint distribution of (X, Y) , and the vertical and horizontal lines through this point separate \mathbb{R}^2 into four quadrants. The function $(x, y) \mapsto [x - \mathbb{E}(X)][y - \mathbb{E}(Y)]$ is positive on the first and third quadrants and negative on the second and fourth.

Figure 4.5.1: A joint distribution with $(\mathbb{E}(X), \mathbb{E}(Y))$ as the center of mass

Properties of Covariance

The following theorems give some basic properties of covariance. The main tool that we will need is the fact that expected value is a linear operation. Other important properties will be derived below, in the subsection on the [best linear predictor](#). As usual, be sure to try the proofs yourself before reading the ones in the text. Once again, we assume that the random variables are defined on the common sample space, are real-valued, and that the indicated expected values exist (as real numbers).

Our first result is a formula that is better than the definition for computational purposes, but gives less insight.

$$\text{cov}(X, Y) = \mathbb{E}(XY) - \mathbb{E}(X)\mathbb{E}(Y).$$

Proof

Let $\mu = \mathbb{E}(X)$ and $\nu = \mathbb{E}(Y)$. Then

$$\text{cov}(X, Y) = \mathbb{E}[(X - \mu)(Y - \nu)] = \mathbb{E}(XY - \mu Y - \nu X + \mu\nu) = \mathbb{E}(XY) - \mu\mathbb{E}(Y) - \nu\mathbb{E}(X) + \mu\nu = \mathbb{E}(XY) - \mu\nu \quad (4.5.3)$$

From (2), we see that X and Y are uncorrelated if and only if $\mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y)$, so here is a simple but important corollary:

If X and Y are independent, then they are uncorrelated.

Proof

We showed in Section 1 that if X and Y are independent then $\mathbb{E}(XY) = \mathbb{E}(X)\mathbb{E}(Y)$.

However, the converse fails with a passion: Exercise (31) gives an example of two variables that are *functionally related* (the strongest form of dependence), yet uncorrelated. The computational exercises give other examples of dependent yet uncorrelated variables also. Note also that if one of the variables has mean 0, then the covariance is simply the expected product.

Trivially, covariance is a symmetric operation.

$$\text{cov}(X, Y) = \text{cov}(Y, X).$$

As the name suggests, covariance generalizes variance.

$$\text{cov}(X, X) = \text{var}(X).$$

Proof

Let $\mu = \mathbb{E}(X)$. Then $\text{cov}(X, X) = \mathbb{E}[(X - \mu)^2] = \text{var}(X)$.

Covariance is a linear operation in the first argument, if the second argument is fixed.

If X, Y, Z are random variables, and c is a constant, then

1. $\text{cov}(X + Y, Z) = \text{cov}(X, Z) + \text{cov}(Y, Z)$
2. $\text{cov}(cX, Y) = c \text{cov}(X, Y)$

Proof

We use the computational formula in (2)

$$1. \quad \text{cov}(X + Y, Z) = \mathbb{E}[(X + Y)Z] - \mathbb{E}(X + Y)\mathbb{E}(Z) = \mathbb{E}(XZ + YZ) - [\mathbb{E}(X) + \mathbb{E}(Y)]\mathbb{E}(Z) \quad (4.5.4)$$

$$= [\mathbb{E}(XZ) - \mathbb{E}(X)\mathbb{E}(Z)] + [\mathbb{E}(YZ) - \mathbb{E}(Y)\mathbb{E}(Z)] = \text{cov}(X, Z) + \text{cov}(Y, Z) \quad (4.5.5)$$

$$2. \quad \text{cov}(cX, Y) = \mathbb{E}(cXY) - \mathbb{E}(cX)\mathbb{E}(Y) = c\mathbb{E}(XY) - c\mathbb{E}(X)\mathbb{E}(Y) = c[\mathbb{E}(XY) - \mathbb{E}(X)\mathbb{E}(Y)] = c \text{cov}(X, Y) \quad (4.5.6)$$

By symmetry, covariance is also a linear operation in the second argument, with the first argument fixed. Thus, the covariance operator is *bi-linear*. The general version of this property is given in the following theorem.

Suppose that (X_1, X_2, \dots, X_n) and (Y_1, Y_2, \dots, Y_m) are sequences of random variables, and that (a_1, a_2, \dots, a_n) and (b_1, b_2, \dots, b_m) are constants. Then

$$\text{cov}\left(\sum_{i=1}^n a_i X_i, \sum_{j=1}^m b_j Y_j\right) = \sum_{i=1}^n \sum_{j=1}^m a_i b_j \text{cov}(X_i, Y_j) \quad (4.5.7)$$

The following result shows how covariance is changed under a linear transformation of one of the variables. This is simply a special case of the basic properties, but is worth stating.

If $a, b \in \mathbb{R}$ then $\text{cov}(a + bX, Y) = b \text{cov}(X, Y)$.

Proof

A constant is independent of any random variable. Hence $\text{cov}(a + bX, Y) = \text{cov}(a, Y) + b \text{cov}(X, Y) = b \text{cov}(X, Y)$.

Of course, by symmetry, the same property holds in the second argument. Putting the two together we have that if $a, b, c, d \in \mathbb{R}$ then $\text{cov}(a + bX, c + dY) = bd \text{cov}(X, Y)$.

Properties of Correlation

Next we will establish some basic properties of correlation. Most of these follow easily from corresponding properties of covariance above. We assume that $\text{var}(X) > 0$ and $\text{var}(Y) > 0$, so that the random variable really are random and hence the correlation is well defined.

The correlation between X and Y is the covariance of the corresponding standard scores:

$$\text{cor}(X, Y) = \text{cov}\left(\frac{X - \mathbb{E}(X)}{\text{sd}(X)}, \frac{Y - \mathbb{E}(Y)}{\text{sd}(Y)}\right) = \mathbb{E}\left(\frac{X - \mathbb{E}(X)}{\text{sd}(X)} \frac{Y - \mathbb{E}(Y)}{\text{sd}(Y)}\right) \quad (4.5.8)$$

Proof

From the definitions and the linearity of expected value,

$$\text{cor}(X, Y) = \frac{\text{cov}(X, Y)}{\text{sd}(X)\text{sd}(Y)} = \frac{\mathbb{E}([X - \mathbb{E}(X)][Y - \mathbb{E}(Y)])}{\text{sd}(X)\text{sd}(Y)} = \mathbb{E}\left(\frac{X - \mathbb{E}(X)}{\text{sd}(X)} \frac{Y - \mathbb{E}(Y)}{\text{sd}(Y)}\right) \quad (4.5.9)$$

Since the standard scores have mean 0, this is also the covariance of the standard scores.

This shows again that correlation is dimensionless, since of course, the standard scores are dimensionless. Also, correlation is symmetric:

$$\text{cor}(X, Y) = \text{cor}(Y, X).$$

Under a linear transformation of one of the variables, the correlation is unchanged if the slope is positive and changes sign if the slope is negative:

If $a, b \in \mathbb{R}$ and $b \neq 0$ then

1. $\text{cor}(a + bX, Y) = \text{cor}(X, Y)$ if $b > 0$
2. $\text{cor}(a + bX, Y) = -\text{cor}(X, Y)$ if $b < 0$

Proof

Let Z denote the standard score of X . If $b > 0$, the standard score of $a + bX$ is also Z . If $b < 0$, the standard score of $a + bX$ is $-Z$. Hence the result follows from the [result above](#) for standard scores.

This result reinforces the fact that correlation is a standardized measure of association, since multiplying the variable by a positive constant is equivalent to a change of scale, and adding a constant to a variable is equivalent to a change of location. For example, in the Challenger data, the underlying variables are temperature at the time of launch (in degrees Fahrenheit) and O-ring erosion (in millimeters). The correlation between these two variables is of fundamental importance. If we decide to measure temperature in degrees Celsius and O-ring erosion in inches, the correlation is unchanged. Of course, the same property holds in the second argument, so if $a, b, c, d \in \mathbb{R}$ with $b \neq 0$ and $d \neq 0$, then $\text{cor}(a + bX, c + dY) = \text{cor}(X, Y)$ if $bd > 0$ and $\text{cor}(a + bX, c + dY) = -\text{cor}(X, Y)$ if $bd < 0$.

The most important properties of covariance and correlation will emerge from our study of the [best linear predictor](#) below.

The Variance of a Sum

We will now show that the variance of a sum of variables is the sum of the pairwise covariances. This result is very useful since many random variables with special distributions can be written as sums of simpler random variables (see in particular the [binomial distribution](#) and [hypergeometric distribution](#) below).

If (X_1, X_2, \dots, X_n) is a sequence of real-valued random variables then

$$\text{var}\left(\sum_{i=1}^n X_i\right) = \sum_{i=1}^n \sum_{j=1}^n \text{cov}(X_i, X_j) = \sum_{i=1}^n \text{var}(X_i) + 2 \sum_{\{(i,j): i < j\}} \text{cov}(X_i, X_j) \quad (4.5.10)$$

Proof

From the variance property on (5), and the linear property (7),

$$\text{var}\left(\sum_{i=1}^n X_i\right) = \text{cov}\left(\sum_{i=1}^n X_i, \sum_{j=1}^n X_j\right) = \sum_{i=1}^n \sum_{j=1}^n \text{cov}(X_i, X_j) \quad (4.5.11)$$

The second expression follows since $\text{cov}(X_i, X_i) = \text{var}(X_i)$ for each i and $\text{cov}(X_i, X_j) = \text{cov}(X_j, X_i)$ for $i \neq j$ by the symmetry property (4)

Note that the variance of a sum can be larger, smaller, or equal to the sum of the variances, depending on the pure covariance terms. As a special case of (12), when $n = 2$, we have

$$\text{var}(X + Y) = \text{var}(X) + \text{var}(Y) + 2 \text{cov}(X, Y) \quad (4.5.12)$$

The following corollary is very important.

If (X_1, X_2, \dots, X_n) is a sequence of pairwise uncorrelated, real-valued random variables then

$$\text{var}\left(\sum_{i=1}^n X_i\right) = \sum_{i=1}^n \text{var}(X_i) \quad (4.5.13)$$

Proof

This follows immediately from (12), since $\text{cov}(X_i, X_j) = 0$ for $i \neq j$.

Note that the last result holds, in particular, if the random variables are independent. We close this discussion with a couple of minor corollaries.

If X and Y are real-valued random variables then $\text{var}(X + Y) + \text{var}(X - Y) = 2[\text{var}(X) + \text{var}(Y)]$.

Proof

From (12),

$$\text{var}(X + Y) = \text{var}(X) + \text{var}(Y) + 2\text{cov}(X, Y) \quad (4.5.14)$$

Similarly,

$$\text{var}(X - Y) = \text{var}(X) + \text{var}(-Y) + 2\text{cov}(X, -Y) = \text{var}(X) + \text{var}(Y) - 2\text{cov}(X, Y) \quad (4.5.15)$$

Adding gives the result.

If X and Y are real-valued random variables with $\text{var}(X) = \text{var}(Y)$ then $X + Y$ and $X - Y$ are uncorrelated.

Proof

From the linear property (7) and the symmetry property (4),
 $\text{cov}(X + Y, X - Y) = \text{cov}(X, X) - \text{cov}(X, Y) + \text{cov}(Y, X) - \text{cov}(Y, Y) = \text{var}(X) - \text{var}(Y)$

Random Samples

In the following exercises, suppose that (X_1, X_2, \dots) is a sequence of independent, real-valued random variables with a common distribution that has mean μ and standard deviation $\sigma > 0$. In statistical terms, the variables form a random sample from the common distribution.

For $n \in \mathbb{N}_+$, let $Y_n = \sum_{i=1}^n X_i$.

1. $\mathbb{E}(Y_n) = n\mu$
2. $\text{var}(Y_n) = n\sigma^2$

Proof

1. This follows from the additive property of expected value.
2. This follows from the additive property of variance ((13) for independent variables)

For $n \in \mathbb{N}_+$, let $M_n = Y_n/n = \frac{1}{n} \sum_{i=1}^n X_i$, so that M_n is the sample mean of (X_1, X_2, \dots, X_n) .

1. $\mathbb{E}(M_n) = \mu$
2. $\text{var}(M_n) = \sigma^2/n$
3. $\text{var}(M_n) \rightarrow 0$ as $n \rightarrow \infty$
4. $\mathbb{P}(|M_n - \mu| > \epsilon) \rightarrow 0$ as $n \rightarrow \infty$ for every $\epsilon > 0$.

Proof

1. This follows from part (a) of the (16) and the scaling property of expected value.
2. This follows from part (b) of the (16) and the scaling property of variance.
3. This is an immediate consequence of (b).
4. This follows from (c) and Chebyshev's inequality: $\mathbb{P}(|M_n - \mu| > \epsilon) \leq \text{var}(M_n)/\epsilon^2 \rightarrow 0$ as $n \rightarrow \infty$

Part (c) of (17) means that $M_n \rightarrow \mu$ as $n \rightarrow \infty$ in mean square. Part (d) means that $M_n \rightarrow \mu$ as $n \rightarrow \infty$ in probability. These are both versions of the weak law of large numbers, one of the fundamental theorems of probability.

The standard score of the sum Y_n and the standard score of the sample mean M_n are the same:

$$Z_n = \frac{Y_n - n\mu}{\sqrt{n}\sigma} = \frac{M_n - \mu}{\sigma/\sqrt{n}} \quad (4.5.16)$$

1. $\mathbb{E}(Z_n) = 0$
2. $\text{var}(Z_n) = 1$

Proof

The equality of the standard score of Y_n and of Z_n is a result of simple algebra. But recall more generally that the standard score of a variable is unchanged by a linear transformation of the variable with positive slope (a location-scale transformation of the distribution). Of course, parts (a) and (b) are true for any standard score.

The central limit theorem, the other fundamental theorem of probability, states that the distribution of Z_n converges to the standard normal distribution as $n \rightarrow \infty$.

Events

If A and B are events in our random experiment then the covariance and correlation of A and B are defined to be the covariance and correlation, respectively, of their indicator random variables.

If A and B are events, define $\text{cov}(A, B) = \text{cov}(\mathbf{1}_A, \mathbf{1}_B)$ and $\text{cor}(A, B) = \text{cor}(\mathbf{1}_A, \mathbf{1}_B)$. Equivalently,

1. $\text{cov}(A, B) = \mathbb{P}(A \cap B) - \mathbb{P}(A)\mathbb{P}(B)$
2. $\text{cor}(A, B) = [\mathbb{P}(A \cap B) - \mathbb{P}(A)\mathbb{P}(B)] / \sqrt{\mathbb{P}(A)[1 - \mathbb{P}(A)] \mathbb{P}(B)[1 - \mathbb{P}(B)]}$

Proof

Recall that if X is an indicator variable with $\mathbb{P}(X = 1) = p$, then $\mathbb{E}(X) = p$ and $\text{var}(X) = p(1 - p)$. Also, if X and Y are indicator variables then XY is an indicator variable and $\mathbb{P}(XY = 1) = \mathbb{P}(X = 1, Y = 1)$. The results then follow from the definitions.

In particular, note that A and B are positively correlated, negatively correlated, or independent, respectively (as defined in the section on conditional probability) if and only if the indicator variables of A and B are positively correlated, negatively correlated, or uncorrelated, as defined in this section.

If A and B are events then

1. $\text{cov}(A, B^c) = -\text{cov}(A, B)$
2. $\text{cov}(A^c, B^c) = \text{cov}(A, B)$

Proof

These results follow from linear property (7) and the fact that $\mathbf{1}_{A^c} = 1 - \mathbf{1}_A$.

If A and B are events with $A \subseteq B$ then

1. $\text{cov}(A, B) = \mathbb{P}(A)[1 - \mathbb{P}(B)]$
2. $\text{cor}(A, B) = \sqrt{\mathbb{P}(A)[1 - \mathbb{P}(B)] / \mathbb{P}(B)[1 - \mathbb{P}(A)]}$

Proof

These results follow from (19), since $A \cap B = A$.

In the language of the experiment, $A \subseteq B$ means that A implies B . In such a case, the events are positively correlated, not surprising.

The Best Linear Predictor

What linear function of X (that is, a function of the form $a + bX$ where $a, b \in \mathbb{R}$) is closest to Y in the sense of minimizing mean square error? The question is fundamentally important in the case where random variable X (the *predictor variable*) is observable and random variable Y (the *response variable*) is not. The linear function can be used to estimate Y from an observed value of X . Moreover, the solution will have the added benefit of showing that covariance and correlation measure the *linear* relationship between X and Y . To avoid trivial cases, let us assume that $\text{var}(X) > 0$ and $\text{var}(Y) > 0$, so that the random variables really are random. The solution to our problem turns out to be the linear function of X with the same expected value as Y , and whose covariance with X is the same as that of Y .

The random variable $L(Y | X)$ defined as follows is the only linear function of X satisfying properties (a) and (b).

$$L(Y | X) = \mathbb{E}(Y) + \frac{\text{cov}(X, Y)}{\text{var}(X)}[X - \mathbb{E}(X)] \quad (4.5.17)$$

1. $\mathbb{E}[L(Y | X)] = \mathbb{E}(Y)$
2. $\text{cov}[X, L(Y | X)] = \text{cov}(X, Y)$

Proof

By the linearity of expected value,

$$\mathbb{E}[L(Y | X)] = \mathbb{E}(Y) + \frac{\text{cov}(X, Y)}{\text{var}(X)}[\mathbb{E}(X) - \mathbb{E}(X)] = \mathbb{E}(Y) \quad (4.5.18)$$

Next, by the linearity of covariance and the fact that a constant is independent (and hence uncorrelated) with any random variable,

$$\text{cov}[X, L(Y | X)] = \frac{\text{cov}(X, Y)}{\text{var}(X)}\text{cov}(X, X) = \frac{\text{cov}(X, Y)}{\text{var}(X)}\text{var}(X) = \text{cov}(X, Y) \quad (4.5.19)$$

Conversely, suppose that $U = a + bX$ satisfies $\mathbb{E}(U) = \mathbb{E}(Y)$ and $\text{cov}(X, U) = \text{cov}(X, Y)$. Again using linearity of covariance and the uncorrelated property of constants, the second equation gives $b \text{cov}(X, X) = \text{cov}(X, Y)$ so $b = \text{cov}(X, Y) / \text{var}(X)$. Then the first equation gives $a = \mathbb{E}(Y) - b\mathbb{E}(X)$, so $U = L(Y | X)$.

Note that in the presence of part (a), part (b) is equivalent to $\mathbb{E}[XL(Y | X)] = \mathbb{E}(XY)$. Here is another minor variation, but one that will be very useful: $L(Y | X)$ is the only linear function of X with the same mean as Y and with the property that $Y - L(Y | X)$ is uncorrelated with every linear function of X .

$L(Y | X)$ is the only linear function of X that satisfies

1. $\mathbb{E}[L(Y | X)] = \mathbb{E}(Y)$
2. $\text{cov}[Y - L(Y | X), U] = 0$ for every linear function U of X .

Proof

Of course part (a) is the same as part (a) of (22). Suppose that $U = a + bX$ where $a, b \in \mathbb{R}$. From basic properties of covariance and the previous result,

$$\text{cov}[Y - L(Y|X), U] = b \text{cov}[Y - L(Y|X), X] = b(\text{cov}(Y, X) - \text{cov}[L(Y|X), X]) = 0 \quad (4.5.20)$$

Conversely, suppose that V is a linear function of X and that $\mathbb{E}(V) = \mathbb{E}(Y)$ and $\text{cov}(Y - V, U) = 0$ for every linear function U of X . Letting $U = X$ we have $\text{cov}(Y - V, X) = 0$ so $\text{cov}(V, X) = \text{cov}(Y, X)$. Hence $V = L(Y|X)$ by (22).

The variance of $L(Y|X)$ and its covariance with Y turn out to be the same.

Additional properties of $L(Y|X)$:

1. $\text{var}[L(Y|X)] = \text{cov}^2(X, Y) / \text{var}(X)$
2. $\text{cov}[L(Y|X), Y] = \text{cov}^2(X, Y) / \text{var}(X)$

Proof

1. From basic properties of variance,

$$\text{var}[L(Y|X)] = \left[\frac{\text{cov}(X, Y)}{\text{var}(X)} \right]^2 \text{var}(X) = \frac{\text{cov}^2(X, Y)}{\text{var}(X)} \quad (4.5.21)$$

2. From basic properties of covariance,

$$\text{cov}[L(Y|X), Y] = \frac{\text{cov}(X, Y)}{\text{var}(X)} \text{cov}(X, Y) = \frac{\text{cov}^2(X, Y)}{\text{var}(X)} \quad (4.5.22)$$

We can now prove the fundamental result that $L(Y|X)$ is the linear function of X that is closest to Y in the mean square sense. We give two proofs; the first is more straightforward, but the second is more interesting and elegant.

Suppose that U is a linear function of X . Then

1. $\mathbb{E}[(Y - L(Y|X))^2] \leq \mathbb{E}[(Y - U)^2]$
2. Equality occurs in (a) if and only if $U = L(Y|X)$ with probability 1.

Proof from calculus

Let $\text{mse}(a, b)$ denote the mean square error when $U = a + bX$ is used as an estimator of Y , as a function of the parameters $a, b \in \mathbb{R}$:

$$\text{mse}(a, b) = \mathbb{E}[(Y - (a + bX))^2] \quad (4.5.23)$$

Expanding the square and using the linearity of expected value gives

$$\text{mse}(a, b) = a^2 + b^2 \mathbb{E}(X^2) + 2ab \mathbb{E}(X) - 2a \mathbb{E}(Y) - 2b \mathbb{E}(XY) + \mathbb{E}(Y^2) \quad (4.5.24)$$

In terms of the variables a and b , the first three terms are the *second-order terms*, the next two are the *first-order terms*, and the last is the *zero-order term*. The second-order terms define a *quadratic form* whose standard symmetric matrix is

$$\begin{bmatrix} 1 & \mathbb{E}(X) \\ \mathbb{E}(X) & \mathbb{E}(X^2) \end{bmatrix} \quad (4.5.25)$$

The determinant of this matrix is $\mathbb{E}(X^2) - [\mathbb{E}(X)]^2 = \text{var}(X)$ and the diagonal terms are positive. All of this means that the graph of mse is a paraboloid opening upward, so the minimum of mse will occur at the unique critical point. Setting the first derivatives of mse to 0 we have

$$-2\mathbb{E}(Y) + 2b\mathbb{E}(X) + 2a = 0 \quad (4.5.26)$$

$$-2\mathbb{E}(XY) + 2b\mathbb{E}(X^2) + 2a\mathbb{E}(X) = 0 \quad (4.5.27)$$

Solving the first equation for a gives $a = \mathbb{E}(Y) - b\mathbb{E}(X)$. Substituting this into the second equation and solving gives $b = \text{cov}(X, Y) / \text{var}(X)$.

Proof using properties

1. We abbreviate $L(Y|X)$ by L for simplicity. Suppose that U is a linear function of X . Then

$$\mathbb{E}[(Y - U)^2] = \mathbb{E}[(Y - L) + (L - U)]^2 = \mathbb{E}[(Y - L)^2] + 2\mathbb{E}[(Y - L)(L - U)] + \mathbb{E}[(L - U)^2] \quad (4.5.28)$$

Since $Y - L$ has mean 0, the middle term is $\text{cov}(Y - L, L - U)$. But L and U are linear functions of X and hence so is $L - U$. Thus $\text{cov}(Y - L, L - U) = 0$ by (23). Hence

$$\mathbb{E}[(Y - U)^2] = \mathbb{E}[(Y - L)^2] + \mathbb{E}[(L - U)^2] \geq \mathbb{E}[(Y - L)^2] \quad (4.5.29)$$

2. Equality occurs in (a) if and only if $\mathbb{E}[(L - U)^2] = 0$, if and only if $\mathbb{P}(L = U) = 1$.

The mean square error when $L(Y | X)$ is used as a predictor of Y is

$$\mathbb{E} \left([Y - L(Y | X)]^2 \right) = \text{var}(Y) [1 - \text{cor}^2(X, Y)] \quad (4.5.30)$$

Proof

Again, let $L = L(Y | X)$ for convenience. Since $Y - L$ has mean 0,

$$\mathbb{E} [(Y - L)^2] = \text{var}(Y - L) = \text{var}(Y) - 2\text{cov}(L, Y) + \text{var}(L) \quad (4.5.31)$$

But $\text{cov}(L, Y) = \text{var}(L) = \text{cov}^2(X, Y) / \text{var}(X)$ by (24). Hence

$$\mathbb{E} [(Y - L)^2] = \text{var}(Y) - \frac{\text{cov}^2(X, Y)}{\text{var}(X)} = \text{var}(Y) \left[1 - \frac{\text{cov}^2(X, Y)}{\text{var}(X)\text{var}(Y)} \right] = \text{var}(Y) [1 - \text{cor}^2(X, Y)] \quad (4.5.32)$$

Our solution to the best linear predictor problems yields important properties of covariance and correlation.

Additional properties of covariance and correlation:

1. $-1 \leq \text{cor}(X, Y) \leq 1$
2. $-\text{sd}(X)\text{sd}(Y) \leq \text{cov}(X, Y) \leq \text{sd}(X)\text{sd}(Y)$
3. $\text{cor}(X, Y) = 1$ if and only if, with probability 1, Y is a linear function of X with positive slope.
4. $\text{cor}(X, Y) = -1$ if and only if, with probability 1, Y is a linear function of X with negative slope.

Proof

Since mean square error is nonnegative, it follows from (26) that $\text{cor}^2(X, Y) \leq 1$. This gives parts (a) and (b). For parts (c) and (d), note that if $\text{cor}^2(X, Y) = 1$ then $Y = L(Y | X)$ with probability 1, and that the slope in $L(Y | X)$ has the same sign as $\text{cor}(X, Y)$.

The last two results clearly show that $\text{cov}(X, Y)$ and $\text{cor}(X, Y)$ measure the *linear* association between X and Y . The equivalent inequalities (a) and (b) above are referred to as the *correlation inequality*. They are also versions of the *Cauchy-Schwarz inequality*, named for Augustin Cauchy and Karl Schwarz

Recall from our previous discussion of variance that the best *constant* predictor of Y , in the sense of minimizing mean square error, is $\mathbb{E}(Y)$ and the minimum value of the mean square error for this predictor is $\text{var}(Y)$. Thus, the difference between the variance of Y and the *mean square error* above for $L(Y | X)$ is the reduction in the variance of Y when the linear term in X is added to the predictor:

$$\text{var}(Y) - \mathbb{E} \left([Y - L(Y | X)]^2 \right) = \text{var}(Y) \text{cor}^2(X, Y) \quad (4.5.33)$$

Thus $\text{cor}^2(X, Y)$ is the *proportion* of reduction in $\text{var}(Y)$ when X is included as a predictor variable. This quantity is called the (distribution) *coefficient of determination*. Now let

$$L(Y | X = x) = \mathbb{E}(Y) + \frac{\text{cov}(X, Y)}{\text{var}(X)} [x - \mathbb{E}(X)], \quad x \in \mathbb{R} \quad (4.5.34)$$

The function $x \mapsto L(Y | X = x)$ is known as the *distribution regression function* for Y given X , and its graph is known as the *distribution regression line*. Note that the regression line passes through $(\mathbb{E}(X), \mathbb{E}(Y))$, the center of the joint distribution.

Figure 4.5.2: The distribution regression line

However, the choice of predictor variable and response variable is crucial.

The regression line for Y given X and the regression line for X given Y are not the same line, except in the trivial case where the variables are perfectly correlated. However, the coefficient of determination is the same, regardless of which variable is the predictor and which is the response.

Proof

The two regression lines are

$$y - \mathbb{E}(Y) = \frac{\text{cov}(X, Y)}{\text{var}(X)} [x - \mathbb{E}(X)] \quad (4.5.35)$$

$$x - \mathbb{E}(X) = \frac{\text{cov}(X, Y)}{\text{var}(Y)} [y - \mathbb{E}(Y)] \quad (4.5.36)$$

The two lines are the same if and only if $\text{cov}^2(X, Y) = \text{var}(X)\text{var}(Y)$. But this is equivalent to $\text{cor}^2(X, Y) = 1$.

Suppose that A and B are events with $0 < \mathbb{P}(A) < 1$ and $0 < \mathbb{P}(B) < 1$. Then

1. $\text{cor}(A, B) = 1$ if and only if $\mathbb{P}(A \setminus B) + \mathbb{P}(B \setminus A) = 0$. (That is, A and B are equivalent events.)
2. $\text{cor}(A, B) = -1$ if and only if $\mathbb{P}(A \setminus B^c) + \mathbb{P}(B^c \setminus A) = 0$. (That is, A and B^c are equivalent events.)

Proof

Recall from (19) that $\text{cor}(A, B) = \text{cor}(\mathbf{1}_A, \mathbf{1}_B)$, so if $\text{cor}^2(A, B) = 1$ then from (27), $\mathbf{1}_B = L(\mathbf{1}_B | \mathbf{1}_A)$ with probability 1. But $\mathbf{1}_A$ and $\mathbf{1}_B$ each takes values 0 and 1 only. Hence the only possible regression lines are $y = 0$, $y = 1$, $y = x$ and $y = 1 - x$. The first two correspond to $\mathbb{P}(B) = 0$ and $\mathbb{P}(B) = 1$, respectively, which are excluded by the hypotheses.

1. In this case, the slope is positive, so the regression line is $y = x$. That is, $\mathbf{1}_B = \mathbf{1}_A$ with probability 1.
2. In this case, the slope is negative, so the regression line is $y = 1 - x$. That is, $\mathbf{1}_B = 1 - \mathbf{1}_A = \mathbf{1}_{A^c}$ with probability 1.

The concept of best linear predictor is more powerful than might first appear, because it can be applied to *transformations* of the variables. Specifically, suppose that X and Y are random variables for our experiment, taking values in general spaces S and T , respectively. Suppose also that g and h are real-valued functions defined on S and T , respectively. We can find $L[h(Y) | g(X)]$, the linear function of $g(X)$ that is closest to $h(Y)$ in the mean square sense. The results of this subsection apply, of course, with $g(X)$ replacing X and $h(Y)$ replacing Y . Of course, we must be able to compute the appropriate means, variances, and covariances.

We close this subsection with two additional properties of the best linear predictor, the *linearity properties*.

Suppose that X , Y , and Z are random variables and that c is a constant. Then

1. $L(Y + Z | X) = L(Y | X) + L(Z | X)$
2. $L(cY | X) = cL(Y | X)$

Proof from the definitions

These results follow easily from the linearity of expected value and covariance.

$$1. \quad L(Y + Z | X) = \mathbb{E}(Y + Z) + \frac{\text{cov}(X, Y + Z)}{\text{var}(X)} [X - \mathbb{E}(X)] \quad (4.5.37)$$

$$= \left(\mathbb{E}(Y) + \frac{\text{cov}(X, Y)}{\text{var}(X)} [X - \mathbb{E}(X)] \right) + \left(\mathbb{E}(Z) + \frac{\text{cov}(X, Z)}{\text{var}(X)} [X - \mathbb{E}(X)] \right) \quad (4.5.38)$$

$$= \mathbb{E}(Y | X) + \mathbb{E}(Z | X) \quad (4.5.39)$$

$$2. \quad L(cY | X) = \mathbb{E}(cY) + \frac{\text{cov}(X, cY)}{\text{var}(X)} [X - \mathbb{E}(X)] = c\mathbb{E}(Y) + c \frac{\text{cov}(X, Y)}{\text{var}(X)} [X - \mathbb{E}(X)] = cL(Y | X) \quad (4.5.40)$$

Proof by characterizing properties

1. We show that $L(Y | X) + L(Z | X)$ satisfy the properties that characterize $L(Y + Z | X)$.

$$\mathbb{E}[L(Y | X) + L(Z | X)] = \mathbb{E}[L(Y | X)] + \mathbb{E}[L(Z | X)] = \mathbb{E}(Y) + \mathbb{E}(Z) = \mathbb{E}(Y + Z) \quad (4.5.41)$$

$$\text{cov}[X, L(Y | X) + L(Z | X)] = \text{cov}[X, L(Y | X)] + \text{cov}[X, L(Z | X)] = \text{cov}(X, Y) + \text{cov}(X, Z) = \text{cov}(X, Y + Z) \quad (4.5.42)$$

2. Similarly, we show that $cL(Y | X)$ satisfies the properties that characterize $L(cY | X)$

$$\mathbb{E}[cL(Y | X)] = c\mathbb{E}[L(Y | X)] = c\mathbb{E}(Y) = \mathbb{E}(cY) \quad (4.5.43)$$

$$\text{cov}[X, cL(Y | X)] = c \text{cov}[X, L(Y | X)] = c \text{cov}(X, Y) = \text{cov}(X, cY) \quad (4.5.44)$$

There are several extensions and generalizations of the ideas in the subsection:

- The corresponding statistical problem of estimating a and b , when these distribution parameters are unknown, is considered in the section on Sample Covariance and Correlation.
- The problem finding the function of X that is closest to Y in the mean square error sense (using *all* reasonable functions, not just linear functions) is considered in the section on Conditional Expected Value.
- The best linear prediction problem when the predictor and response variables are random vectors is considered in the section on Expected Value and Covariance Matrices.

The use of characterizing properties will play a crucial role in these extensions.

Examples and Applications

Uniform Distributions

Suppose that X is uniformly distributed on the interval $[-1, 1]$ and $Y = X^2$. Then X and Y are uncorrelated even though Y is a function of X (the strongest form of dependence).

Proof

Note that $\mathbb{E}(X) = 0$ and $\mathbb{E}(Y) = \mathbb{E}(X^2) = 1/3$ and $\mathbb{E}(XY) = \mathbb{E}(X^3) = 0$. Hence $\text{cov}(X, Y) = \mathbb{E}(XY) - \mathbb{E}(X)\mathbb{E}(Y) = 0$.

Suppose that (X, Y) is uniformly distributed on the region $S \subseteq \mathbb{R}^2$. Find $\text{cov}(X, Y)$ and $\text{cor}(X, Y)$ and determine whether the variables are independent in each of the following cases:

1. $S = [a, b] \times [c, d]$ where $a < b$ and $c < d$, so S is a rectangle.
2. $S = \{(x, y) \in \mathbb{R}^2 : -a \leq y \leq x \leq a\}$ where $a > 0$, so S is a triangle
3. $S = \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 \leq r^2\}$ where $r > 0$, so S is a circle

Answer

1. $\text{cov}(X, Y) = 0$, $\text{cor}(X, Y) = 0$. X and Y are independent.
2. $\text{cov}(X, Y) = \frac{a^2}{9}$, $\text{cor}(X, Y) = \frac{1}{2}$. X and Y are dependent.
3. $\text{cov}(X, Y) = 0$, $\text{cor}(X, Y) = 0$. X and Y are dependent.

In the bivariate uniform experiment, select each of the regions below in turn. For each region, run the simulation 2000 times and note the value of the correlation and the shape of the cloud of points in the scatterplot. Compare with the results in the last exercise.

1. Square
2. Triangle
3. Circle

Suppose that X is uniformly distributed on the interval $(0, 1)$ and that given $X = x \in (0, 1)$, Y is uniformly distributed on the interval $(0, x)$. Find each of the following:

1. $\text{cov}(X, Y)$
2. $\text{cor}(X, Y)$
3. $L(Y | X)$
4. $L(X | Y)$

Answer

1. $\frac{1}{24}$
2. $\sqrt{\frac{3}{7}}$
3. $\frac{1}{2}X$
4. $\frac{2}{7} + \frac{6}{7}Y$

Dice

Recall that a *standard die* is a six-sided die. A *fair die* is one in which the faces are equally likely. An *ace-six flat die* is a standard die in which faces 1 and 6 have probability $\frac{1}{4}$ each, and faces 2, 3, 4, and 5 have probability $\frac{1}{8}$ each.

A pair of standard, fair dice are thrown and the scores (X_1, X_2) recorded. Let $Y = X_1 + X_2$ denote the sum of the scores, $U = \min\{X_1, X_2\}$ the minimum scores, and $V = \max\{X_1, X_2\}$ the maximum score. Find the covariance and correlation of each of the following pairs of variables:

1. (X_1, X_2)
2. (X_1, Y)
3. (X_1, U)
4. (U, V)
5. (U, Y)

Answer

1. 0, 0
2. $\frac{35}{12}, \frac{1}{\sqrt{2}} = 0.7071$
3. $\frac{35}{24}, 0.6082$
4. $\frac{1369}{1296}, \frac{1369}{2555} = 0.5358$
5. $\frac{35}{12}, 0.8601$

Suppose that n fair dice are thrown. Find the mean and variance of each of the following variables:

1. Y_n , the sum of the scores.
2. M_n , the average of the scores.

Answer

1. $\mathbb{E}(Y_n) = \frac{7}{2}n$, $\text{var}(Y_n) = \frac{35}{12}n$
2. $\mathbb{E}(M_n) = \frac{7}{2}$, $\text{var}(M_n) = \frac{35}{12n}$

In the dice experiment, select fair dice, and select the following random variables. In each case, increase the number of dice and observe the size and location of the probability density function and the mean \pm standard deviation bar. With $n = 20$ dice, run the experiment 1000 times and compare the sample mean and standard deviation to the distribution mean and standard deviation.

1. The sum of the scores.
2. The average of the scores.

Suppose that n ace-six flat dice are thrown. Find the mean and variance of each of the following variables:

1. Y_n , the sum of the scores.
2. M_n , the average of the scores.

Answer

1. $n\frac{7}{2}$, $n\frac{15}{4}$
2. $\frac{7}{2}$, $\frac{15}{4n}$

In the dice experiment, select ace-six flat dice, and select the following random variables. In each case, increase the number of dice and observe the size and location of the probability density function and the mean \pm standard deviation bar. With $n = 20$ dice, run the experiment 1000 times and compare the sample mean and standard deviation to the distribution mean and standard deviation.

1. The sum of the scores.
2. The average of the scores.

A pair of fair dice are thrown and the scores (X_1, X_2) recorded. Let $Y = X_1 + X_2$ denote the sum of the scores, $U = \min\{X_1, X_2\}$ the minimum score, and $V = \max\{X_1, X_2\}$ the maximum score. Find each of the following:

1. $L(Y | X_1)$
2. $L(U | X_1)$
3. $L(V | X_1)$

Answer

1. $\frac{7}{2} + X_1$
2. $\frac{7}{9} + \frac{1}{2}X_1$
3. $\frac{49}{19} + \frac{1}{2}X_1$

Bernoulli Trials

Recall that a *Bernoulli trials process* is a sequence $\mathbf{X} = (X_1, X_2, \dots)$ of independent, identically distributed indicator random variables. In the usual language of reliability, X_i denotes the outcome of trial i , where 1 denotes success and 0 denotes failure. The probability of success $p = \mathbb{P}(X_i = 1)$ is the basic parameter of the process. The process is named for Jacob Bernoulli. A separate chapter on the Bernoulli Trials explores this process in detail.

For $n \in \mathbb{N}_+$, the number of successes in the first n trials is $Y_n = \sum_{i=1}^n X_i$. Recall that this random variable has the binomial distribution with parameters n and p , which has probability density function f given by

$$f_n(y) = \binom{n}{y} p^y (1-p)^{n-y}, \quad y \in \{0, 1, \dots, n\} \quad (4.5.45)$$

The mean and variance of Y_n are

1. $\mathbb{E}(Y_n) = np$
2. $\text{var}(Y_n) = np(1-p)$

Proof

These results could be derived from the PDF of Y_n , of course, but a derivation based on the sum of IID variables is much better. Recall that $\mathbb{E}(X_i) = p$ and $\text{var}(X_i) = p(1-p)$ so the results follow immediately from theorem (16).

In the binomial coin experiment, select the number of heads. Vary n and p and note the shape of the probability density function and the size and location of the mean \pm standard deviation bar. For selected values of the parameters, run the experiment 1000 times and compare the sample mean

and standard deviation to the distribution mean and standard deviation.

For $n \in \mathbb{N}_+$, the proportion of successes in the first n trials is $M_n = Y_n/n$. This random variable is sometimes used as a statistical estimator of the parameter p , when the parameter is unknown.

The mean and variance of M_n are

1. $\mathbb{E}(M_n) = p$
2. $\text{var}(M_n) = p(1-p)/n$

Proof

Recall that $\mathbb{E}(X_i) = p$ and $\text{var}(X_i) = p(1-p)$ so the results follow immediately from theorem (17).

In the binomial coin experiment, select the proportion of heads. Vary n and p and note the shape of the probability density function and the size and location of the mean \pm standard deviation bar. For selected values of the parameters, run the experiment 1000 times and compare the sample mean and standard deviation to the distribution mean and standard deviation.

As a special case of (17) note that $M_n \rightarrow p$ as $n \rightarrow \infty$ in mean square and in probability.

The Hypergeometric Distribution

Suppose that a population consists of m objects; r of the objects are type 1 and $m-r$ are type 0. A sample of n objects is chosen at random, without replacement. The parameters $m, n \in \mathbb{N}_+$ and $r \in \mathbb{N}$ with $n \leq m$ and $r \leq m$. For $i \in \{1, 2, \dots, n\}$, let X_i denote the type of the i th object selected. Recall that (X_1, X_2, \dots, X_n) is a sequence of identically distributed (but *not* independent) indicator random variables.

Let Y denote the number of type 1 objects in the sample, so that $Y = \sum_{i=1}^n X_i$. Recall that this random variable has the hypergeometric distribution, which has probability density function f_n given by

$$f(y) = \frac{\binom{r}{y} \binom{m-r}{n-y}}{\binom{m}{n}}, \quad y \in \{0, 1, \dots, n\} \quad (4.5.46)$$

For distinct $i, j \in \{1, 2, \dots, n\}$,

1. $\mathbb{E}(X_i) = \frac{r}{m}$
2. $\text{var}(X_i) = \frac{r}{m} \left(1 - \frac{r}{m}\right)$
3. $\text{cov}(X_i, X_j) = -\frac{r}{m} \left(1 - \frac{r}{m}\right) \frac{1}{m-1}$
4. $\text{cor}(X_i, X_j) = -\frac{1}{m-1}$

Proof

Recall that $\mathbb{E}(X_i) = \mathbb{P}(X_i = 1) = \frac{r}{m}$ for each i and $\mathbb{E}(X_i X_j) = \mathbb{P}(X_i = 1, X_j = 1) = \frac{r}{m} \frac{r-1}{m-1}$ for each $i \neq j$. Technically, the sequence of indicator variables is exchangeable. The results now follow from the definitions and simple algebra.

Note that the event of a type 1 object on draw i and the event of a type 1 object on draw j are negatively correlated, but the correlation depends only on the population size and not on the number of type 1 objects. Note also that the correlation is perfect if $m = 2$. Think about these result intuitively.

The mean and variance of Y are

1. $\mathbb{E}(Y) = n \frac{r}{m}$
2. $\text{var}(Y) = n \frac{r}{m} \left(1 - \frac{r}{m}\right) \frac{m-n}{m-1}$

Proof

Again, a derivation from the representation of Y as a sum of indicator variables is far preferable to a derivation based on the PDF of Y . These results follow immediately from (45), the additive property of expected value, and Theorem (12).

Note that if the sampling were *with* replacement, Y would have a binomial distribution, and so in particular $E(Y) = n \frac{r}{m}$ and $\text{var}(Y) = n \frac{r}{m} \left(1 - \frac{r}{m}\right)$. The additional factor $\frac{m-n}{m-1}$ that occurs in the variance of the hypergeometric distribution is sometimes called the *finite population correction factor*. Note that for fixed m , $\frac{m-n}{m-1}$ is decreasing in n , and is 0 when $n = m$. Of course, we know that we must have $\text{var}(Y) = 0$ if $n = m$, since we would be sampling the entire population, and so deterministically, $Y = r$. On the other hand, for fixed n , $\frac{m-n}{m-1} \rightarrow 1$ as $m \rightarrow \infty$. More generally, the hypergeometric distribution is well approximated by the binomial when the population size m is large compared to the sample size n . These ideas are discussed more fully in the section on the hypergeometric distribution in the chapter on Finite Sampling Models.

In the ball and urn experiment, select sampling without replacement. Vary m, r , and n and note the shape of the probability density function and the size and location of the mean \pm standard deviation bar. For selected values of the parameters, run the experiment 1000 times and compare the sample mean and standard deviation to the distribution mean and standard deviation.

Exercises on Basic Properties

Suppose that X and Y are real-valued random variables with $\text{cov}(X, Y) = 3$. Find $\text{cov}(2X - 5, 4Y + 2)$.

Answer

24

Suppose X and Y are real-valued random variables with $\text{var}(X) = 5$, $\text{var}(Y) = 9$, and $\text{cov}(X, Y) = -3$. Find

1. $\text{cor}(X, Y)$
2. $\text{var}(2X + 3Y - 7)$
3. $\text{cov}(5X + 2Y - 3, 3X - 4Y + 2)$
4. $\text{cor}(5X + 2Y - 3, 3X - 4Y + 2)$

Answer

1. $-\frac{1}{\sqrt{5}} \approx -0.4472$
2. 65
3. 45
4. $\frac{15}{\sqrt{2929}} \approx 0.2772$

Suppose that X and Y are independent, real-valued random variables with $\text{var}(X) = 6$ and $\text{var}(Y) = 8$. Find $\text{var}(3X - 4Y + 5)$.

Answer

182

Suppose that A and B are events in an experiment with $\mathbb{P}(A) = \frac{1}{2}$, $\mathbb{P}(B) = \frac{1}{3}$, and $\mathbb{P}(A \cap B) = \frac{1}{8}$. Find each of the following:

1. $\text{cov}(A, B)$
2. $\text{cor}(A, B)$

Answer

1. $-\frac{1}{24}$
2. $-\sqrt{2}/8$

Suppose that X , Y , and Z are real-valued random variables for an experiment, and that $L(Y | X) = 2 - 3X$ and $L(Z | X) = 5 + 4X$. Find $L(6Y - 2Z | X)$.

Answer

$2 - 26X$

Suppose that X and Y are real-valued random variables for an experiment, and that $\mathbb{E}(X) = 3$, $\text{var}(X) = 4$, and $L(Y | X) = 5 - 2X$. Find each of the following:

1. $\mathbb{E}(Y)$
2. $\text{cov}(X, Y)$

Answer

1. -1
2. -8

Simple Continuous Distributions

Suppose that (X, Y) has probability density function f given by $f(x, y) = x + y$ for $0 \leq x \leq 1$, $0 \leq y \leq 1$. Find each of the following

1. $\text{cov}(X, Y)$
2. $\text{cor}(X, Y)$
3. $L(Y | X)$
4. $L(X | Y)$

Answer

1. $-\frac{1}{144}$
2. $-\frac{1}{11} \approx -0.0909$
3. $\frac{7}{11} - \frac{1}{11}X$
4. $\frac{7}{11} = \frac{1}{11}Y$

Suppose that (X, Y) has probability density function f given by $f(x, y) = 2(x + y)$ for $0 \leq x \leq y \leq 1$. Find each of the following:

1. $\text{cov}(X, Y)$
2. $\text{cor}(X, Y)$
3. $L(Y | X)$
4. $L(X | Y)$

Answer

1. $\frac{1}{48}$
2. $\frac{5}{\sqrt{129}} \approx 0.4402$
3. $\frac{26}{43} + \frac{15}{43}X$
4. $\frac{5}{9}Y$

Suppose again that (X, Y) has probability density function f given by $f(x, y) = 2(x + y)$ for $0 \leq x \leq y \leq 1$.

1. Find $\text{cov}(X^2, Y)$.
2. Find $\text{cor}(X^2, Y)$.
3. Find $L(Y | X^2)$.
4. Which predictor of Y is better, the one based on X or the one based on X^2 ?

Answer

1. $\frac{7}{360}$
2. 0.448
3. $\frac{1255}{1920} + \frac{245}{634}X$
4. The predictor based on X^2 is slightly better.

Suppose that (X, Y) has probability density function f given by $f(x, y) = 6x^2y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$. Find each of the following:

1. $\text{cov}(X, Y)$
2. $\text{cor}(X, Y)$
3. $L(Y | X)$
4. $L(X | Y)$

Answer

Note that X and Y are independent.

1. 0
2. 0
3. $\frac{2}{3}$
4. $\frac{3}{4}$

Suppose that (X, Y) has probability density function f given by $f(x, y) = 15x^2y$ for $0 \leq x \leq y \leq 1$. Find each of the following:

1. $\text{cov}(X, Y)$
2. $\text{cor}(X, Y)$
3. $L(Y | X)$
4. $L(X | Y)$

Answer

1. $\frac{5}{336}$
2. 0.05423
3. $\frac{30}{51} + \frac{20}{51}X$
4. $\frac{3}{4}Y$

Suppose again that (X, Y) has probability density function f given by $f(x, y) = 15x^2y$ for $0 \leq x \leq y \leq 1$.

1. Find $\text{cov}(\sqrt{X}, Y)$.
2. Find $\text{cor}(\sqrt{X}, Y)$.
3. Find $L(Y | \sqrt{X})$.
4. Which of the predictors of Y is better, the one based on X or the one based on \sqrt{X} ?

Answer

1. $\frac{10}{1001}$
2. $\frac{24}{169}\sqrt{14}$

3. $\frac{5225}{13\,182} + \frac{1232}{2197}X$

4. The predictor based on X is slightly better.

4.6: Generating Functions

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. A *generating function* of a real-valued random variable is an expected value of a certain transformation of the random variable involving another (deterministic) variable. Most generating functions share four important properties:

1. Under mild conditions, the generating function completely determines the distribution of the random variable.
2. The generating function of a sum of independent variables is the product of the generating functions
3. The moments of the random variable can be obtained from the derivatives of the generating function.
4. Ordinary (pointwise) convergence of a sequence of generating functions corresponds to the special convergence of the corresponding distributions.

Property 1 is perhaps the most important. Often a random variable is shown to have a certain distribution by showing that the generating function has a certain form. The process of recovering the distribution from the generating function is known as *inversion*. Property 2 is frequently used to determine the distribution of a sum of independent variables. By contrast, recall that the probability density function of a sum of independent variables is the convolution of the individual density functions, a much more complicated operation. Property 3 is useful because often computing moments from the generating function is easier than computing the moments directly from the probability density function. The last property is known as the *continuity theorem*. Often it is easier to show the convergence of the generating functions than to prove convergence of the distributions directly.

The numerical value of the generating function at a particular value of the free variable is of no interest, and so generating functions can seem rather unintuitive at first. But the important point is that the generating function as a whole encodes all of the information in the probability distribution in a very useful way. Generating functions are important and valuable tools in probability, as they are in other areas of mathematics, from combinatorics to differential equations.

We will study the three generating functions in the list below, which correspond to increasing levels of generality. The first is the most restrictive, but also by far the simplest, since the theory reduces to basic facts about power series that you will remember from calculus. The third is the most general and the one for which the theory is most complete and elegant, but it also requires basic knowledge of complex analysis. The one in the middle is perhaps the one most commonly used, and suffices for most distributions in applied probability.

1. [the probability generating function](#)
2. [the moment generating function](#)
3. [the characteristic function](#)

We will also study the characteristic function for multivariate distributions, although analogous results hold for the other two types. In the basic theory below, be sure to try the proofs yourself before reading the ones in the text.

Basic Theory

The Probability Generating Function

For our first generating function, assume that N is a random variable taking values in \mathbb{N} .

The *probability generating function* P of N is defined by

$$P(t) = \mathbb{E}(t^N) \quad (4.6.1)$$

for all $t \in \mathbb{R}$ for which the expected value exists in \mathbb{R} .

That is, $P(t)$ is defined when $\mathbb{E}(|t|^N) < \infty$. The probability generating function can be written nicely in terms of the probability density function.

Suppose that N has probability density function f and probability generating function P . Then

$$P(t) = \sum_{n=0}^{\infty} f(n)t^n, \quad t \in (-r, r) \quad (4.6.2)$$

where $r \in [1, \infty]$ is the radius of convergence of the series.

Proof

The expansion follows from the discrete change of variables theorem for expected value. Note that the series is a power series in t , and hence by basic calculus, converges absolutely for $t \in (-r, r)$ where $r \in [0, \infty]$ is the radius of convergence. But since $\sum_{n=0}^{\infty} f(n) = 1$ we must have $r \geq 1$, and the series converges absolutely at least for $t \in [-1, 1]$.

In the language of combinatorics, P is the *ordinary generating function* of f . Of course, if N just takes a finite set of values in \mathbb{N} then $r = \infty$. Recall from calculus that a power series can be differentiated term by term, just like a polynomial. Each derivative series has the same radius of convergence as the original series (but may behave differently at the endpoints of the interval of convergence). We denote the derivative of order n by $P^{(n)}$. Recall also that if $n \in \mathbb{N}$ and $k \in \mathbb{N}$ with $k \leq n$, then the number of permutations of size k chosen from a population of n objects is

$$n^{(k)} = n(n-1) \cdots (n-k+1) \quad (4.6.3)$$

The following theorem is the inversion result for probability generating functions: the generating function completely determines the distribution.

Suppose again that N has probability density function f and probability generating function P . Then

$$f(k) = \frac{P^{(k)}(0)}{k!}, \quad k \in \mathbb{N} \quad (4.6.4)$$

Proof

This is a standard result from the theory of power series. Differentiating k times gives $P^{(k)}(t) = \sum_{n=k}^{\infty} n^{(k)} f(n) t^{n-k}$ for $t \in (-r, r)$. Hence $P^{(k)}(0) = k^{(k)} f(k) = k! f(k)$

Our next result is not particularly important, but has a certain curiosity.

$$\mathbb{P}(N \text{ is even}) = \frac{1}{2} [1 + P(-1)] .$$

Proof

Note that

$$P(1) + P(-1) = \sum_{n=0}^{\infty} f(n) + \sum_{n=0}^{\infty} (-1)^n f(n) = 2 \sum_{k=0}^{\infty} f(2k) = 2\mathbb{P}(N \text{ is even}) \quad (4.6.5)$$

We can combine the two sum since we know that the series converge absolutely at 1 and -1 .

Recall that the *factorial moment* of N of order $k \in \mathbb{N}$ is $\mathbb{E}[N^{(k)}]$. The factorial moments can be computed from the derivatives of the probability generating function. The factorial moments, in turn, determine the ordinary moments about 0 (sometimes referred to as *raw moments*).

Suppose that the radius of convergence $r > 1$. Then $P^{(k)}(1) = \mathbb{E}[N^{(k)}]$ for $k \in \mathbb{N}$. In particular, N has finite moments of all orders.

Proof

As before, $P^{(k)}(t) = \sum_{n=k}^{\infty} n^{(k)} f(n) t^{n-k}$ for $t \in (-r, r)$. Hence if $r > 1$ then $P^{(k)}(1) = \sum_{n=k}^{\infty} n^{(k)} f(n) = \mathbb{E}[N^{(k)}]$

Suppose again that $r > 1$. Then

1. $\mathbb{E}(N) = P'(1)$
2. $\text{var}(N) = P''(1) + P'(1)[1 - P'(1)]$

Proof

1. $\mathbb{E}(N) = \mathbb{E}[N^{(1)}] = P'(1)$.
2. $\mathbb{E}(N^2) = \mathbb{E}[N(N-1)] + \mathbb{E}(N) = \mathbb{E}[N^{(2)}] + \mathbb{E}(N) = P''(1) + P'(1)$. Hence from (a),
 $\text{var}(N) = P''(1) + P'(1) - [P'(1)]^2$.

Suppose that N_1 and N_2 are independent random variables taking values in \mathbb{N} , with probability generating functions P_1 and P_2 having radii of convergence r_1 and r_2 , respectively. Then the probability generating function P of $N_1 + N_2$ is given by $P(t) = P_1(t)P_2(t)$ for $|t| < r_1 \wedge r_2$.

Proof

Recall that the expected product of independent variables is the product of the expected values. Hence

$$P(t) = \mathbb{E}(t^{N_1+N_2}) = \mathbb{E}(t^{N_1}t^{N_2}) = \mathbb{E}(t^{N_1})\mathbb{E}(t^{N_2}) = P_1(t)P_2(t), \quad |t| < r_1 \wedge r_2 \quad (4.6.6)$$

The Moment Generating Function

Our next generating function is defined more generally, so in this discussion we assume that the random variables are real-valued.

The *moment generating function* of X is the function M defined by

$$M(t) = \mathbb{E}(e^{tX}), \quad t \in \mathbb{R} \quad (4.6.7)$$

Note that since $e^{tX} \geq 0$ with probability 1, $M(t)$ exists, as a real number or ∞ , for any $t \in \mathbb{R}$. But as we will see, our interest will be in the domain where $M(t) < \infty$.

Suppose that X has a continuous distribution on \mathbb{R} with probability density function f . Then

$$M(t) = \int_{-\infty}^{\infty} e^{tx} f(x) dx \quad (4.6.8)$$

Proof

This follows from the change of variables theorem for expected value.

Thus, the moment generating function of X is closely related to the *Laplace transform* of the probability density function f . The Laplace transform is named for Pierre Simon Laplace, and is widely used in many areas of applied mathematics, particularly differential equations. The basic inversion theorem for moment generating functions (similar to the inversion theorem for Laplace transforms) states that if $M(t) < \infty$ for t in an open interval about 0, then M completely determines the distribution of X . Thus, if two distributions on \mathbb{R} have moment generating functions that are equal (and finite) in an open interval about 0, then the distributions are the same.

Suppose that X has moment generating function M that is finite in an open interval I about 0. Then X has moments of all orders and

$$M(t) = \sum_{n=0}^{\infty} \frac{\mathbb{E}(X^n)}{n!} t^n, \quad t \in I \quad (4.6.9)$$

Proof

Under the hypotheses, the expected value operator can be interchanged with the infinite series for the exponential function:

$$M(t) = \mathbb{E}(e^{tX}) = \mathbb{E}\left(\sum_{n=0}^{\infty} \frac{X^n}{n!} t^n\right) = \sum_{n=0}^{\infty} \frac{\mathbb{E}(X^n)}{n!} t^n, \quad t \in I \quad (4.6.10)$$

The interchange is a special case of *Fubini's theorem*, named for Guido Fubini. For more details see the advanced section on properties of the integral in the chapter on Distributions.

So under the finite assumption in the [last theorem](#), the moment generating function, like the probability generating function, is a power series in t .

Suppose again that X has moment generating function M that is finite in an open interval about 0. Then $M^{(n)}(0) = \mathbb{E}(X^n)$ for $n \in \mathbb{N}$

Proof

This follows by the same argument as above for the [PGF](#): $M^{(n)}(0)/n!$ is the coefficient of order n in the [power series](#) above, namely $\mathbb{E}(X^n)/n!$. Hence $M^{(n)}(0) = \mathbb{E}(X^n)$.

Thus, the derivatives of the moment generating function at 0 determine the moments of the variable (hence the name). In the language of combinatorics, the moment generating function is the *exponential generating function* of the sequence of moments. Thus, a random variable that does not have finite moments of all orders cannot have a finite moment generating function. Even when a random variable *does* have moments of all orders, the moment generating function may not exist. A [counterexample](#) is constructed below.

For nonnegative random variables (which are very common in applications), the domain where the moment generating function is finite is easy to understand.

Suppose that X takes values in $[0, \infty)$ and has moment generating function M . If $M(t) < \infty$ for $t \in \mathbb{R}$ then $M(s) < \infty$ for $s \leq t$.

Proof

Since $X \geq 0$, if $s \leq t$ then $sX \leq tX$ and hence $e^{sX} \leq e^{tX}$. Hence $\mathbb{E}(e^{sX}) \leq \mathbb{E}(e^{tX})$.

So for a nonnegative random variable, either $M(t) < \infty$ for all $t \in \mathbb{R}$ or there exists $r \in (0, \infty)$ such that $M(t) < \infty$ for $t < r$. Of course, there are complementary results for non-positive random variables, but such variables are much less common. Next we consider what happens to the moment generating function under some simple transformations of the random variables.

Suppose that X has moment generating function M and that $a, b \in \mathbb{R}$. The moment generating function N of $Y = a + bX$ is given by $N(t) = e^{at} M(bt)$ for $t \in \mathbb{R}$.

Proof

$\mathbb{E}[e^{t(a+bX)}] = \mathbb{E}(e^{ta} e^{tbX}) = e^{ta} \mathbb{E}[e^{(tb)X}] = e^{at} M(bt)$ for $t \in \mathbb{R}$.

Recall that if $a \in \mathbb{R}$ and $b \in (0, \infty)$ then the transformation $a + bX$ is a *location-scale* transformation on the distribution of X , with *location parameter* a and *scale parameter* b . Location-scale transformations frequently arise when units are changed, such as length changed from inches to centimeters or temperature from degrees Fahrenheit to degrees Celsius.

Suppose that X_1 and X_2 are independent random variables with moment generating functions M_1 and M_2 respectively. The moment generating function M of $Y = X_1 + X_2$ is given by $M(t) = M_1(t)M_2(t)$ for $t \in \mathbb{R}$.

Proof

As with the PGF, the proof for the MGF relies on the law of exponents and the fact that the expected value of a product of independent variables is the product of the expected values:

$$\mathbb{E}[e^{t(X_1+X_2)}] = \mathbb{E}(e^{tX_1} e^{tX_2}) = \mathbb{E}(e^{tX_1}) \mathbb{E}(e^{tX_2}) = M_1(t)M_2(t), \quad t \in \mathbb{R} \quad (4.6.11)$$

The probability generating function of a variable can easily be converted into the moment generating function of the variable.

Suppose that X is a random variable taking values in \mathbb{N} with [probability generating function](#) G having radius of convergence r . The moment generating function M of X is given by $M(t) = G(e^t)$ for $t < \ln(r)$.

Proof

$M(t) = \mathbb{E}(e^{tX}) = \mathbb{E}[(e^t)^X] = G(e^t)$ for $e^t < r$.

The following theorem gives the *Chernoff bounds*, named for the mathematician Herman Chernoff. These are upper bounds on the tail events of a random variable.

If X has moment generating function M then

1. $\mathbb{P}(X \geq x) \leq e^{-tx} M(t)$ for $t > 0$
2. $\mathbb{P}(X \leq x) \leq e^{-tx} M(t)$ for $t < 0$

Proof

1. From Markov's inequality, $\mathbb{P}(X \geq x) = \mathbb{P}(e^{tX} \geq e^{tx}) \leq \mathbb{E}(e^{tX}) / e^{tx} = e^{-tx} M(t)$ if $t > 0$.
2. Similarly, $\mathbb{P}(X \leq x) = \mathbb{P}(e^{tX} \geq e^{tx}) \leq e^{-tx} M(t)$ if $t < 0$.

Naturally, the best Chernoff bound (in either (a) or (b)) is obtained by finding t that minimizes $e^{-tx} M(t)$.

The Characteristic Function

Our last generating function is the nicest from a mathematical point of view. Once again, we assume that our random variables are real-valued.

The *characteristic function* of X is the function χ defined by

$$\chi(t) = \mathbb{E}(e^{itX}) = \mathbb{E}[\cos(tX)] + i\mathbb{E}[\sin(tX)], \quad t \in \mathbb{R} \quad (4.6.12)$$

Note that χ is a complex valued function, and so this subsection requires some basic knowledge of complex analysis. The function χ is defined for all $t \in \mathbb{R}$ because the random variable in the expected value is bounded in magnitude. Indeed, $|e^{itX}| = 1$ for all $t \in \mathbb{R}$. Many of the properties of the characteristic function are more elegant than the corresponding properties of the probability or moment generating functions, because the characteristic function always exists.

If X has a continuous distribution on \mathbb{R} with probability density function f and characteristic function χ then

$$\chi(t) = \int_{-\infty}^{\infty} e^{itx} f(x) dx, \quad t \in \mathbb{R} \quad (4.6.13)$$

Proof

This follows from the change of variables theorem for expected value, albeit a complex version.

Thus, the characteristic function of X is closely related to the *Fourier transform* of the probability density function f . The Fourier transform is named for Joseph Fourier, and is widely used in many areas of applied mathematics.

As with other generating functions, the characteristic function completely determines the distribution. That is, random variables X and Y have the same distribution if and only if they have the same characteristic function. Indeed, the general *inversion formula* given next is a formula for computing certain combinations of probabilities from the characteristic function.

Suppose again that X has characteristic function χ . If $a, b \in \mathbb{R}$ and $a < b$ then

$$\int_{-n}^n \frac{e^{-iat} - e^{-ibt}}{2\pi it} \chi(t) dt \rightarrow \mathbb{P}(a < X < b) + \frac{1}{2}[\mathbb{P}(X = b) - \mathbb{P}(X = a)] \text{ as } n \rightarrow \infty \quad (4.6.14)$$

The probability combinations on the right side completely determine the distribution of X . A special inversion formula holds for continuous distributions:

Suppose that X has a continuous distribution with probability density function f and characteristic function χ . At every point $x \in \mathbb{R}$ where f is differentiable,

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-itx} \chi(t) dt \quad (4.6.15)$$

This formula is essentially the *inverse Fourier transform*. As with the other generating functions, the characteristic function can be used to find the moments of X . Moreover, this can be done even when only some of the moments exist.

Suppose again that X has characteristic function χ . If $n \in \mathbb{N}_+$ and $\mathbb{E}(|X^n|) < \infty$. Then

$$\chi(t) = \sum_{k=0}^n \frac{\mathbb{E}(X^k)}{k!} (it)^k + o(t^n) \quad (4.6.16)$$

and therefore $\chi^{(n)}(0) = i^n \mathbb{E}(X^n)$.

Details

Recall that the last term is a generic function that satisfies $o(t^n)/t^n \rightarrow 0$ as $t \rightarrow \infty$.

Next we consider how the characteristic function is changed under some simple transformations of the variables.

Suppose that X has characteristic function χ and that $a, b \in \mathbb{R}$. The characteristic function ψ of $Y = a + bX$ is given by $\psi(t) = e^{iat} \chi(bt)$ for $t \in \mathbb{R}$.

Proof

The proof is just like the one for the MGF: $\psi(t) = \mathbb{E} [e^{it(a+bX)}] = \mathbb{E} (e^{ita} e^{itbX}) = e^{ita} \mathbb{E} [e^{i(tb)X}] = e^{iat} \chi(bt)$ for $t \in \mathbb{R}$.

Suppose that X_1 and X_2 are independent random variables with characteristic functions χ_1 and χ_2 respectively. The characteristic function χ of $Y = X_1 + X_2$ is given by $\chi(t) = \chi_1(t) \chi_2(t)$ for $t \in \mathbb{R}$.

Proof

Again, the proof is just like the one for the MGF:

$$\chi(t) = \mathbb{E} [e^{it(X_1+X_2)}] = \mathbb{E} (e^{itX_1} e^{itX_2}) = \mathbb{E} (e^{itX_1}) \mathbb{E} (e^{itX_2}) = \chi_1(t) \chi_2(t), \quad t \in \mathbb{R} \quad (4.6.17)$$

The characteristic function of a random variable can be obtained from the moment generating function, under the basic existence condition that we saw earlier.

Suppose that X has moment generating function M that satisfies $M(t) < \infty$ for t in an open interval I about 0. Then the characteristic function χ of X satisfies $\chi(t) = M(it)$ for $t \in I$.

The final important property of characteristic functions that we will discuss relates to convergence in distribution. Suppose that (X_1, X_2, \dots) is a sequence of real-valued random with characteristic functions (χ_1, χ_2, \dots) respectively. Since we are only concerned with distributions, the random variables need not be defined on the same probability space.

The Continuity Theorem

1. If the distribution of X_n converges to the distribution of a random variable X as $n \rightarrow \infty$ and X has characteristic function χ , then $\chi_n(t) \rightarrow \chi(t)$ as $n \rightarrow \infty$ for all $t \in \mathbb{R}$.
2. Conversely, if $\chi_n(t)$ converges to a function $\chi(t)$ as $n \rightarrow \infty$ for t in an open interval about 0, and if χ is continuous at 0, then χ is the characteristic function of a random variable X , and the distribution of X_n converges to the distribution of X as $n \rightarrow \infty$.

There are analogous versions of the continuity theorem for probability generating functions and moment generating functions. The continuity theorem can be used to prove the central limit theorem, one of the fundamental theorems of probability. Also, the continuity theorem has a straightforward generalization to distributions on \mathbb{R}^n .

The Joint Characteristic Function

All of the generating functions that we have discussed have multivariate extensions. However, we will discuss the extension only for the characteristic function, the most important and versatile of the generating functions. There are analogous results for the other generating functions. So in this discussion, we assume that (X, Y) is a random vector for our experiment, taking values in \mathbb{R}^2 .

The (joint) *characteristic function* χ of (X, Y) is defined by

$$\chi(s, t) = \mathbb{E} [\exp(isX + itY)], \quad (s, t) \in \mathbb{R}^2 \quad (4.6.18)$$

Once again, the most important fact is that χ completely determines the distribution: two random vectors taking values in \mathbb{R}^2 have the same characteristic function if and only if they have the same distribution.

The joint moments can be obtained from the derivatives of the characteristic function.

Suppose that (X, Y) has characteristic function χ . If $m, n \in \mathbb{N}$ and $\mathbb{E} (|X^m Y^n|) < \infty$ then

$$\chi^{(m,n)}(0, 0) = e^{i(m+n)} \mathbb{E} (X^m Y^n) \quad (4.6.19)$$

The marginal characteristic functions and the characteristic function of the sum can be easily obtained from the joint characteristic function:

Suppose again that (X, Y) has characteristic function χ , and let χ_1 , χ_2 , and χ_+ denote the characteristic functions of X , Y , and $X + Y$, respectively. For $t \in \mathbb{R}$

1. $\chi(t, 0) = \chi_1(t)$
2. $\chi(0, t) = \chi_2(t)$
3. $\chi(t, t) = \chi_+(t)$

Proof

All three results follow immediately from the definitions.

Suppose again that χ_1 , χ_2 , and χ are the characteristic functions of X , Y , and (X, Y) respectively. Then X and Y are independent if and only if $\chi(s, t) = \chi_1(s)\chi_2(t)$ for all $(s, t) \in \mathbb{R}^2$.

Naturally, the results for bivariate characteristic functions have analogies in the general multivariate case. Only the notation is more complicated.

Examples and Applications

As always, be sure to try the computational problems yourself before expanding the solutions and answers in the text.

Dice

Recall that an *ace-six flat die* is a six-sided die for which faces numbered 1 and 6 have probability $\frac{1}{4}$ each, while faces numbered 2, 3, 4, and 5 have probability $\frac{1}{8}$ each. Similarly, a *3-4 flat die* is a six-sided die for which faces numbered 3 and 4 have probability $\frac{1}{4}$ each, while faces numbered 1, 2, 5, and 6 have probability $\frac{1}{8}$ each.

Suppose that an ace-six flat die and a 3-4 flat die are rolled. Use probability generating functions to find the probability density function of the sum of the scores.

Solution

Let X and Y denote the score on the ace-six die and 3-4 flat die, respectively. Then X and Y have PGFs P and Q given by

$$\begin{aligned} P(t) &= \frac{1}{4}t + \frac{1}{8}t^2 + \frac{1}{8}t^3 + \frac{1}{8}t^4 + \frac{1}{8}t^5 + \frac{1}{4}t^6, \quad t \in \mathbb{R} \\ Q(t) &= \frac{1}{8}t + \frac{1}{8}t^2 + \frac{1}{4}t^3 + \frac{1}{4}t^4 + \frac{1}{8}t^5 + \frac{1}{8}t^6, \quad t \in \mathbb{R} \end{aligned}$$

Hence $X + Y$ has PGF PQ . Expanding (a computer algebra program helps) gives

$$P(t)Q(t) = \frac{1}{32}t^2 + \frac{3}{64}t^3 + \frac{3}{32}t^4 + \frac{1}{8}t^5 + \frac{1}{8}t^6 + \frac{5}{32}t^7 + \frac{1}{8}t^8 + \frac{1}{8}t^9 + \frac{3}{32}t^{10} + \frac{3}{64}t^{11} + \frac{1}{32}t^{12}, \quad t \in \mathbb{R} \quad (4.6.20)$$

Thus the PDF f of $X + Y$ is given by $f(2) = f(12) = \frac{1}{32}$, $f(3) = f(11) = \frac{3}{64}$, $f(4) = f(10) = \frac{3}{32}$, $f(5) = f(6) = f(8) = f(9) = \frac{1}{8}$ and $f(7) = \frac{5}{32}$.

Two fair, 6-sided dice are rolled. One has faces numbered $(0, 1, 2, 3, 4, 5)$ and the other has faces numbered $(0, 6, 12, 18, 24, 30)$. Use probability generating functions to find the probability density function of the sum of the scores, and identify the distribution.

Solution

Let X and Y denote the score on the first die and the second die described, respectively. Then X and Y have PGFs P and Q given by

$$\begin{aligned} P(t) &= \frac{1}{6} \sum_{k=0}^5 t^k \quad t \in \mathbb{R} \\ Q(t) &= \frac{1}{6} \sum_{j=0}^5 t^{6j} \quad t \in \mathbb{R} \end{aligned}$$

Hence $X + Y$ has PGF PQ . Simplifying gives

$$P(t)Q(t) = \frac{1}{36} \sum_{j=0}^5 \sum_{k=0}^5 t^{6j+k} = \frac{1}{36} \sum_{n=0}^{35} t^n, \quad t \in \mathbb{R} \quad (4.6.21)$$

Hence $X + Y$ is uniformly distributed on $\{0, 1, 2, \dots, 35\}$

Suppose that random variable Y has probability generating function P given by

$$P(t) = \left(\frac{2}{5}t + \frac{3}{10}t^2 + \frac{1}{5}t^3 + \frac{1}{10}t^4 \right)^5, \quad t \in \mathbb{R} \quad (4.6.22)$$

1. Interpret Y in terms of rolling dice.
2. Use the probability generating function to find the first two factorial moments of Y .
3. Use (b) to find the variance of Y .

Answer

1. A four-sided die has faces numbered $(1, 2, 3, 4)$ with respective probabilities $\left(\frac{2}{5}, \frac{3}{10}, \frac{1}{5}, \frac{1}{10}\right)$. Y is the sum of the scores when the die is rolled 5 times.
2. $\mathbb{E}(Y) = P'(1) = 10$, $\mathbb{E}[Y(Y-1)] = P''(1) = 95$
3. $\text{var}(Y) = 5$

Bernoulli Trials

Suppose X is an indicator random variable with $p = \mathbb{P}(X = 1)$, where $p \in [0, 1]$ is a parameter. Then X has probability generating function $P(t) = 1 - p + pt$ for $t \in \mathbb{R}$.

Proof

$$P(t) = \mathbb{E}(t^X) = t^0(1-p) + t^1p = 1 - p + pt \quad \text{for } t \in \mathbb{R}.$$

Recall that a *Bernoulli trials process* is a sequence (X_1, X_2, \dots) of independent, identically distributed indicator random variables. In the usual language of reliability, X_i denotes the outcome of trial i , where 1 denotes success and 0 denotes failure. The probability of success $p = \mathbb{P}(X_i = 1)$ is the basic parameter of the process. The process is named for Jacob Bernoulli. A separate chapter on the Bernoulli Trials explores this process in more detail.

For $n \in \mathbb{N}_+$, the number of successes in the first n trials is $Y_n = \sum_{i=1}^n X_i$. Recall that this random variable has the binomial distribution with parameters n and p , which has probability density function f_n given by

$$f_n(y) = \binom{n}{y} p^y (1-p)^{n-y}, \quad y \in \{0, 1, \dots, n\} \quad (4.6.23)$$

Random variable Y_n has probability generating function P_n given by $P_n(t) = (1 - p + pt)^n$ for $t \in \mathbb{R}$.

Proof

This follows immediately from the [PGF of an indicator variable](#) and the result for [sums of independent variables](#).

Random variable Y_n has the following parameters:

1. $\mathbb{E}[Y_n^{(k)}] = n^{(k)} p^k$
2. $\mathbb{E}(Y_n) = np$
3. $\text{var}(Y_n) = np(1-p)$
4. $\mathbb{P}(Y_n \text{ is even}) = \frac{1}{2}[1 - (1-2p)^n]$

Proof

1. Repeated differentiation gives $P^{(k)}(t) = n^{(k)} p^k (1-p+pt)^{n-k}$. Hence $P^{(k)}(1) = n^{(k)} p^k$, which is $\mathbb{E}[X^{(k)}]$ by the [moment result](#) above.
2. This follows from the [formula for mean](#).
3. This follows from the [formula for variance](#).
4. This follows from the [even value formula](#).

Suppose that U has the binomial distribution with parameters $m \in \mathbb{N}_+$ and $p \in [0, 1]$, V has the binomial distribution with parameters $n \in \mathbb{N}_+$ and $q \in [0, 1]$, and that U and V are independent.

1. If $p = q$ then $U + V$ has the binomial distribution with parameters $m + n$ and p .
2. If $p \neq q$ then $U + V$ does not have a binomial distribution.

Proof

From the [result for sums of independent variables](#) and the [PGF of the binomial distribution](#), note that the probability generating function of $U + V$ is $P(t) = (1 - p + pt)^m (1 - q + qt)^n$ for $t \in \mathbb{R}$.

1. If $p = q$ then $U + V$ has PGF $P(t) = (1 - p + pt)^{m+n}$, which is the PGF of the binomial distribution with parameters $m + n$ and p .
2. On the other hand, if $p \neq q$, the PGF P does not have the functional form of a binomial PGF.

Suppose now that $p \in (0, 1]$. The trial number N of the first success in the sequence of Bernoulli trials has the *geometric distribution* on \mathbb{N}_+ with success parameter p . The probability density function h is given by

$$h(n) = p(1 - p)^{n-1}, \quad n \in \mathbb{N}_+ \quad (4.6.24)$$

The geometric distribution is studied in more detail in the chapter on Bernoulli trials.

Let Q denote the probability generating function of N . Then

1. $Q(t) = \frac{pt}{1 - (1-p)t}$ for $-\frac{1}{1-p} < t < \frac{1}{1-p}$
2. $\mathbb{E}[N^{(k)}] = k! \frac{(1-p)^{k-1}}{p^k}$ for $k \in \mathbb{N}$
3. $\mathbb{E}(N) = \frac{1}{p}$
4. $\text{var}(N) = \frac{1-p}{p^2}$
5. $\mathbb{P}(N \text{ is even}) = \frac{1-p}{2-p}$

Proof

1. Using the formula for the sum of a geometric series,

$$Q(t) = \sum_{n=1}^{\infty} (1-p)^{n-1} p t^n = p t \sum_{n=1}^{\infty} [(1-p)t]^{n-1} = \frac{pt}{1 - (1-p)t}, \quad |(1-p)t| < 1 \quad (4.6.25)$$

2. Repeated differentiation gives $H^{(k)}(t) = k! p (1-p)^{k-1} [1 - (1-p)t]^{-(k+1)}$ and then the result follows from the [inversion formula](#).
3. This follows from (b) and the [formula for mean](#).
4. This follows from (b) and the [formula for variance](#).
5. This follows from [even value formula](#).

The probability that N is even comes up in the alternating coin tossing game with two players.

The Poisson Distribution

Recall that the *Poisson distribution* has probability density function f given by

$$f(n) = e^{-a} \frac{a^n}{n!}, \quad n \in \mathbb{N} \quad (4.6.26)$$

where $a \in (0, \infty)$ is a parameter. The Poisson distribution is named after Simeon Poisson and is widely used to model the number of “random points” in a region of time or space; the parameter is proportional to the size of the region of time or space. The Poisson distribution is studied in more detail in the chapter on the Poisson Process.

Suppose that N has Poisson distribution with parameter $a \in (0, \infty)$. Let P_a denote the probability generating function of N . Then

1. $P_a(t) = e^{a(t-1)}$ for $t \in \mathbb{R}$
2. $\mathbb{E}[N^{(k)}] = a^k$
3. $\mathbb{E}(N) = a$
4. $\text{var}(N) = a$

$$5. \mathbb{P}(N \text{ is even}) = \frac{1}{2}(1 + e^{-2a})$$

Proof

1. Using the exponential series,

$$P_a(t) = \sum_{n=0}^{\infty} e^{-a} \frac{a^n}{n!} t^n = e^{-a} \sum_{n=0}^{\infty} \frac{(at)^n}{n!} = e^{-a} e^{at}, \quad t \in \mathbb{R} \quad (4.6.27)$$

2. Repeated differentiation gives $P_a^{(k)}(t) = e^{a(t-1)} a^k$, so the result follows from [inversion formula](#).

3. This follows from (b) and the [formula for mean](#).

4. This follows from (b) and the [formula for variance](#).

5. This follows from [even value formula](#).

The Poisson family of distributions is closed with respect to sums of independent variables, a very important property.

Suppose that X, Y have Poisson distributions with parameters $a, b \in (0, \infty)$, respectively, and that X and Y are independent. Then $X + Y$ has the Poisson distribution with parameter $a + b$.

Proof

In the notation of the [previous result](#), note that $P_a P_b = P_{a+b}$.

The right distribution function of the Poisson distribution does not have a simple, closed-form expression. The following exercise gives an upper bound.

Suppose that N has the Poisson distribution with parameter $a > 0$. Then

$$\mathbb{P}(N \geq n) \leq e^{n-a} \left(\frac{a}{n}\right)^n, \quad n > a \quad (4.6.28)$$

Proof

The PGF of N is $P(t) = e^{a(t-1)}$ and hence the MGF is $P(e^t) = \exp(ae^t - a)$. From the [Chernov bounds](#) we have

$$\mathbb{P}(N \geq n) \leq e^{-tn} \exp(ae^t - a) = \exp(ae^t - a - tn) \quad (4.6.29)$$

If $n > a$ the expression on the right is minimized when $t = \ln(n/a)$. Substituting gives the upper bound.

The following theorem gives an important convergence result that is explored in more detail in the chapter on the Poisson process.

Suppose that $p_n \in (0, 1)$ for $n \in \mathbb{N}_+$ and that $np_n \rightarrow a \in (0, \infty)$ as $n \rightarrow \infty$. Then the binomial distribution with parameters n and p_n converges to the Poisson distribution with parameter a as $n \rightarrow \infty$.

Proof

Let P_n denote the probability generating function of the binomial distribution with parameters n and p_n . From the [PGF of the binomial distribution](#) we have

$$P_n(t) = [1 + p_n(t-1)]^n = \left[1 + \frac{np_n(t-1)}{n}\right]^n, \quad t \in \mathbb{R} \quad (4.6.30)$$

Using a famous theorem from calculus, $P_n(t) \rightarrow e^{a(t-1)}$ as $n \rightarrow \infty$. But this is the PGF of the Poisson distribution with parameter a , so the result follows from the continuity theorem for PGFs.

The Exponential Distribution

Recall that the *exponential distribution* is a continuous distribution on $[0, \infty)$ with probability density function f given by

$$f(t) = re^{-rt}, \quad t \in (0, \infty) \quad (4.6.31)$$

where $r \in (0, \infty)$ is the *rate parameter*. This distribution is widely used to model failure times and other random times, and in particular governs the time between arrivals in the Poisson model. The exponential distribution is studied in more detail in the chapter on the Poisson Process.

Suppose that T has the exponential distribution with rate parameter $r \in (0, \infty)$ and let M denote the moment generating function of T . Then

1. $M(s) = \frac{r}{r-s}$ for $s \in (-\infty, r)$.
2. $\mathbb{E}(T^n) = n!/r^n$ for $n \in \mathbb{N}$

Proof

1. $M(s) = \mathbb{E}(e^{sT}) = \int_0^\infty e^{st} r e^{-rt} dt = \int_0^\infty r e^{(s-r)t} dt = \frac{r}{r-s}$ for $s < r$.
2. $M^{(n)}(s) = \frac{r n!}{(r-s)^{n+1}}$ for $n \in \mathbb{N}$

Suppose that (T_1, T_2, \dots) is a sequence of independent random variables, each having the exponential distribution with rate parameter $r \in (0, \infty)$. For $n \in \mathbb{N}_+$, the moment generating function M_n of $U_n = \sum_{i=1}^n T_i$ is given by

$$M_n(s) = \left(\frac{r}{r-s} \right)^n, \quad s \in (-\infty, r) \quad (4.6.32)$$

Proof

This follows from the [previous result](#) and the result for [sums of independent variables](#).

Random variable U_n has the *Erlang distribution* with shape parameter n and rate parameter r , named for Agner Erlang. This distribution governs the n th arrival time in the Poisson model. The Erlang distribution is a special case of the gamma distribution and is studied in more detail in the chapter on the Poisson Process.

Uniform Distributions

Suppose that $a, b \in \mathbb{R}$ and $a < b$. Recall that the continuous uniform distribution on the interval $[a, b]$ has probability density function f given by

$$f(x) = \frac{1}{b-a}, \quad x \in [a, b] \quad (4.6.33)$$

The distribution corresponds to selecting a point *at random* from the interval. Continuous uniform distributions arise in geometric probability and a variety of other applied problems.

Suppose that X is uniformly distributed on the interval $[a, b]$ and let M denote the moment generating function of X . Then

1. $M(t) = \frac{e^{bt} - e^{at}}{(b-a)t}$ if $t \neq 0$ and $M(0) = 1$
2. $\mathbb{E}(X^n) = \frac{b^{n+1} - a^{n+1}}{(n+1)(b-a)}$ for $n \in \mathbb{N}$

Proof

1. $M(t) = \int_a^b e^{tx} \frac{1}{b-a} dx = \frac{e^{bt} - e^{at}}{(b-a)t}$ if $t \neq 0$. Trivially $M(0) = 1$
2. This is a case where the MGF is not helpful, and it's much easier to compute the moments directly:

$$\mathbb{E}(X^n) = \int_a^b x^n \frac{1}{b-a} dx = \frac{b^{n+1} - a^{n+1}}{(n+1)(b-a)}$$

Suppose that (X, Y) is uniformly distributed on the triangle $T = \{(x, y) \in \mathbb{R}^2 : 0 \leq x \leq y \leq 1\}$. Compute each of the following:

1. The joint moment generating function of (X, Y) .
2. The moment generating function of X .
3. The moment generating function of Y .
4. The moment generating function of $X + Y$.

Answer

1. $M(s, t) = 2 \frac{e^{s+t} - 1}{s(s+t)} - 2 \frac{e^t - 1}{st}$ if $s \neq 0, t \neq 0$. $M(0, 0) = 1$
2. $M_1(s) = 2 \left(\frac{e^2}{s^2} - \frac{1}{s^2} - \frac{1}{s} \right)$ if $s \neq 0$. $M_1(0) = 1$
3. $M_2(t) = 2 \frac{te^t - e^t + 1}{t^2}$ if $t \neq 0$. $M_2(0) = 1$
4. $M_+(t) = \frac{e^{2t} - 1}{t^2} - 2 \frac{e^t - 1}{t^2}$ if $t \neq 0$. $M_+(0) = 1$

A Bivariate Distribution

Suppose that (X, Y) has probability density function f given by $f(x, y) = x + y$ for $(x, y) \in [0, 1]^2$. Compute each of the following:

1. The joint moment generating function (X, Y) .
2. The moment generating function of X .
3. The moment generating function of Y .
4. The moment generating function of $X + Y$.

Answer

1. $M(s, t) = \frac{e^{s+t}(-2st+s+t)+e^s(st-s-t)+s+t}{s^2t^2}$ if $s \neq 0, t \neq 0$. $M(0, 0) = 1$
2. $M_1(s) = \frac{3se^2-2e^2-s+2}{2s^2}$ if $s \neq 0$. $M_1(0) = 1$
3. $M_2(t) = \frac{3te^2-2e^2-t+2}{2t^2}$ if $t \neq 0$. $M_2(0) = 1$
4. $M_+(t) = \frac{[e^{2t}(1-t)+e^t(t-2)+1]}{t^3}$ if $t \neq 0$. $M_+(0) = 1$

The Normal Distribution

Recall that the *standard normal distribution* is a continuous distribution on \mathbb{R} with probability density function ϕ given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2}, \quad z \in \mathbb{R} \quad (4.6.34)$$

Normal distributions are widely used to model physical measurements subject to small, random errors and are studied in more detail in the chapter on Special Distributions.

Suppose that Z has the standard normal distribution and let M denote the moment generating function of Z . Then

1. $M(t) = e^{\frac{1}{2}t^2}$ for $t \in \mathbb{R}$
2. $\mathbb{E}(Z^n) = 1 \cdot 3 \cdots (n-1)$ if n is even and $\mathbb{E}(Z^n) = 0$ if n is odd.

Proof

1. First,

$$M(t) = \mathbb{E}(e^{tZ}) = \int_{-\infty}^{\infty} e^{tz} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2} + tz\right) dz \quad (4.6.35)$$

Completing the square in z gives $\exp\left(-\frac{z^2}{2} + tz\right) = \exp\left[\frac{1}{2}t^2 - \frac{1}{2}(z-t)^2\right] = e^{\frac{1}{2}t^2} \exp\left[-\frac{1}{2}(z-t)^2\right]$. hence

$$M(t) = e^{\frac{1}{2}t^2} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left[-\frac{1}{2}(z-t)^2\right] dz = e^{\frac{1}{2}t^2} \quad (4.6.36)$$

because the function of z in the last integral is the probability density function for the normal distribution with mean t and variance 1.

2. Note that $M'(t) = tM(t)$. Thus, repeated differentiation gives $M^{(n)}(t) = p_n(t)M(t)$ for $n \in \mathbb{N}$, where p_n is a polynomial of degree n satisfying $p'_{n+1}(t) = tp_n(t) + p'_n(t)$. Since $p_0 = 1$, it's easy to see that p_n has only even or only odd terms, depending on whether n is even or odd, respectively. Thus, $\mathbb{E}(X^n) = p_n(0)$. This is 0 if n is odd, and is the constant term $1 \cdot 3 \cdots (n-1)$ if n is even. Of course, we can also see that the odd order moments must be 0 by symmetry.

More generally, for $\mu \in \mathbb{R}$ and $\sigma \in (0, \infty)$, recall that the normal distribution with mean μ and standard deviation σ is a continuous distribution on \mathbb{R} with probability density function f given by

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right], \quad x \in \mathbb{R} \quad (4.6.37)$$

Moreover, if Z has the standard normal distribution, then $X = \mu + \sigma Z$ has the normal distribution with mean μ and standard deviation σ . Thus, we can easily find the moment generating function of X :

Suppose that X has the normal distribution with mean μ and standard deviation σ . The moment generating function of X is

$$M(t) = \exp\left(\mu t + \frac{1}{2}\sigma^2 t^2\right), \quad t \in \mathbb{R} \quad (4.6.38)$$

Proof

This follows easily the [previous result](#) and the result for [linear transformations](#): $X = \mu + \sigma Z$ where Z has the standard normal distribution. Hence

$$M(t) = \mathbb{E}(e^{tX}) = e^{\mu t} \mathbb{E}(e^{\sigma t Z}) = e^{\mu t} e^{\frac{1}{2}\sigma^2 t^2}, \quad t \in \mathbb{R} \quad (4.6.39)$$

So the normal family of distributions is closed under location-scale transformations. The family is also closed with respect to sums of independent variables:

If X and Y are independent, normally distributed random variables then $X + Y$ has a normal distribution.

Proof

Suppose that X has the normal distribution with mean $\mu \in \mathbb{R}$ and standard deviation $\sigma \in (0, \infty)$, and that Y has the normal distribution with mean $\nu \in \mathbb{R}$ and standard deviation $\tau \in (0, \infty)$. By [\(14\)](#), the MGF of $X + Y$ is

$$M_{X+Y}(t) = M_X(t)M_Y(t) = \exp\left(\mu t + \frac{1}{2}\sigma^2 t^2\right) \exp\left(\nu t + \frac{1}{2}\tau^2 t^2\right) = \exp\left[(\mu + \nu)t + \frac{1}{2}(\sigma^2 + \tau^2)t^2\right] \quad (4.6.40)$$

which we recognize as the MGF of the normal distribution with mean $\mu + \nu$ and variance $\sigma^2 + \tau^2$. Of course, we already knew that $\mathbb{E}(X + Y) = \mathbb{E}(X) + \mathbb{E}(Y)$, and since X and Y are independent, $\text{var}(X + Y) = \text{var}(X) + \text{var}(Y)$, so the new information is that the distribution is also normal.

The Pareto Distribution

Recall that the *Pareto distribution* is a continuous distribution on $[1, \infty)$ with probability density function f given by

$$f(x) = \frac{a}{x^{a+1}}, \quad x \in [1, \infty) \quad (4.6.41)$$

where $a \in (0, \infty)$ is the shape parameter. The Pareto distribution is named for Vilfredo Pareto. It is a heavy-tailed distribution that is widely used to model financial variables such as income. The Pareto distribution is studied in more detail in the chapter on Special Distributions.

Suppose that X has the Pareto distribution with shape parameter a , and let M denote the moment generating function of X . Then

1. $\mathbb{E}(X^n) = \frac{a}{a-n}$ if $n < a$ and $\mathbb{E}(X^n) = \infty$ if $n \geq a$
2. $M(t) = \infty$ for $t > 0$

Proof

1. We have seen this computation before. $\mathbb{E}(X^n) = \int_1^\infty x^n \frac{a}{x^{a+1}} dx = \int_1^\infty x^{n-a-1} dx$. The integral evaluates to $\frac{a}{a-n}$ if $n < a$ and ∞ if $n \geq a$.
2. This follows from part (a). Since $X \geq 1$, $M(t)$ is increasing in t . Thus $M(t) \leq 1$ if $t < 0$. If $M(t) < \infty$ for some $t > 0$, then $M(t)$ would be finite for t in an open interval about 0, in which case X would have finite moments of all orders. Of course, it's also easy to see directly from the integral that $M(t) = \infty$ for $t > 0$.

On the other hand, like all distributions on \mathbb{R} , the Pareto distribution has a characteristic function. However, the characteristic function of the Pareto distribution does not have a simple, closed form.

The Cauchy Distribution

Recall that the (standard) *Cauchy distribution* is a continuous distribution on \mathbb{R} with probability density function f given by

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad x \in \mathbb{R} \quad (4.6.42)$$

and is named for Augustin Cauchy. The Cauchy distribution is studied in more generality in the chapter on Special Distributions. The graph of f is known as the *Witch of Agnesi*, named for Maria Agnesi.

Suppose that X has the standard Cauchy distribution, and let M denote the moment generating function of X . Then

1. $\mathbb{E}(X)$ does not exist.
2. $M(t) = \infty$ for $t \neq 0$.

Proof

1. We have seen this computation before. $\int_a^\infty \frac{x}{\pi(1+x^2)} dx = \infty$ and $\int_{-\infty}^a \frac{x}{\pi(1+x^2)} dx = -\infty$ for every $a \in \mathbb{R}$, so $\int_{-\infty}^\infty \frac{x}{\pi(1+x^2)} dx$ does not exist.
2. Note that $\int_0^\infty \frac{e^{tx}}{\pi(1+x^2)} dx = \infty$ if $t \geq 0$ and $\int_{-\infty}^0 \frac{e^{tx}}{\pi(1+x^2)} dx = \infty$ if $t \leq 0$.

Once again, all distributions on \mathbb{R} have characteristic functions, and the standard Cauchy distribution has a particularly simple one.

Let χ denote the characteristic function of X . Then $\chi(t) = e^{-|t|}$ for $t \in \mathbb{R}$.

Proof

The proof of this result requires contour integrals in the complex plane, and is given in the section on the Cauchy distribution in the chapter on special distributions.

Counterexample

For the Pareto distribution, only some of the moments are finite; so course, the moment generating function cannot be finite in an interval about 0. We will now give an example of a distribution for which *all* of the moments are finite, yet still the moment generating function is not finite in any interval about 0. Furthermore, we will see two different distributions that have the same moments of all orders.

Suppose that Z has the standard normal distribution and let $X = e^Z$. The distribution of X is known as the (standard) *lognormal distribution*. The lognormal distribution is studied in more generality in the chapter on Special Distributions. This distribution has finite moments of all orders, but infinite moment generating function.

X has probability density function f given by

$$f(x) = \frac{1}{\sqrt{2\pi}x} \exp\left(-\frac{1}{2}\ln^2(x)\right), \quad x > 0 \quad (4.6.43)$$

1. $\mathbb{E}(X^n) = e^{\frac{1}{2}n^2}$ for $n \in \mathbb{N}$.
2. $\mathbb{E}(e^{tX}) = \infty$ for $t > 0$.

Proof

We use the change of variables theorem. The transformation is $x = e^z$ so the inverse transformation is $z = \ln x$ for $x \in (0, \infty)$ and $z \in \mathbb{R}$. Letting ϕ denote the PDF of Z , it follows that the PDF of X is $f(x) = \phi(z) dz/dx = \phi(\ln x)/x$ for $x > 0$.

1. We use the moment generating function of the standard normal distribution given [above](#): $\mathbb{E}(X^n) = \mathbb{E}(e^{nZ}) = e^{n^2/2}$.
2. Note that

$$\mathbb{E}(e^{tX}) = \mathbb{E}\left[\sum_{n=0}^{\infty} \frac{(tX)^n}{n!}\right] = \sum_{n=0}^{\infty} \frac{\mathbb{E}(X^n)}{n!} t^n = \sum_{n=0}^{\infty} \frac{e^{n^2/2}}{n!} t^n = \infty, \quad t > 0 \quad (4.6.44)$$

The interchange of expected value and sum is justified since X is nonnegative. See the advanced section on properties of the integral in the chapter on Distributions for more details.

Next we construct a different distribution with the same moments as X .

Let h be the function defined by $h(x) = \sin(2\pi \ln x)$ for $x > 0$ and let g be the function defined by $g(x) = f(x)[1 + h(x)]$ for $x > 0$. Then

1. g is a probability density function.
2. If Y has probability density function g then $\mathbb{E}(Y^n) = e^{\frac{1}{2}n^2}$ for $n \in \mathbb{N}$

Proof

Figure 4.6.1: The graphs of f and g , probability density functions for two distributions with the same moments of all orders.

4.7: Conditional Expected Value

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} the collection of events, and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) . Suppose next that X is a random variable taking values in a set S and that Y is a random variable taking values in $T \subseteq \mathbb{R}$. We assume that either Y has a discrete distribution, so that T is countable, or that Y has a continuous distribution so that T is an interval (or perhaps a union of intervals). In this section, we will study the conditional expected value of Y given X , a concept of fundamental importance in probability. As we will see, the expected value of Y given X is the function of X that best approximates Y in the mean square sense. Note that X is a general random variable, not necessarily real-valued, but as usual, we will assume that either X has a discrete distribution, so that S is countable or that X has a continuous distribution on $S \subseteq \mathbb{R}^n$ for some $n \in \mathbb{N}_+$. In the latter case, S is typically a region defined by inequalities involving elementary functions. We will also assume that all expected values that are mentioned exist (as real numbers).

Basic Theory

Definitions

Note that we can think of (X, Y) as a random variable that takes values in the Cartesian product set $S \times T$. We need recall some basic facts from our work with joint distributions and conditional distributions.

We assume that (X, Y) has joint probability density function f and we let g denote the (marginal) probability density function X . Recall that if Y has a discrete distribution then

$$g(x) = \sum_{y \in T} f(x, y), \quad x \in S \quad (4.7.1)$$

and if Y has a continuous distribution then

$$g(x) = \int_T f(x, y) dy, \quad x \in S \quad (4.7.2)$$

In either case, for $x \in S$, the conditional probability density function of Y given $X = x$ is defined by

$$h(y | x) = \frac{f(x, y)}{g(x)}, \quad y \in T \quad (4.7.3)$$

We are now ready for the basic definitions:

For $x \in S$, the *conditional expected value* of Y given $X = x \in S$ is simply the mean computed relative to the conditional distribution. So if Y has a discrete distribution then

$$E(Y | X = x) = \sum_{y \in T} yh(y | x), \quad x \in S \quad (4.7.4)$$

and if Y has a continuous distribution then

$$E(Y | X = x) = \int_T yh(y | x) dy, \quad x \in S \quad (4.7.5)$$

1. The function $v : S \rightarrow \mathbb{R}$ defined by $v(x) = E(Y | X = x)$ for $x \in S$ is the *regression function* of Y based on X .
2. The random variable $v(X)$ is called the *conditional expected value* of Y given X and is denoted $E(Y | X)$.

Intuitively, we treat X as known, and therefore not random, and we then average Y with respect to the probability distribution that remains. The advanced section on conditional expected value gives a much more general definition that unifies the definitions given here for the various distribution types.

Properties

The most important property of the random variable $E(Y | X)$ is given in the following theorem. In a sense, this result states that $E(Y | X)$ behaves just like Y in terms of other functions of X , and is essentially the only function of X with this property.

The fundamental property

1. $E[r(X)E(Y | X)] = E[r(X)Y]$ for every function $r : S \rightarrow \mathbb{R}$.
2. If $u : S \rightarrow \mathbb{R}$ satisfies $E[r(X)u(X)] = E[r(X)Y]$ for every $r : S \rightarrow \mathbb{R}$ then $\mathbb{P}[u(X) = E(Y | X)] = 1$.

Proof

We give the proof in the continuous case. The discrete case is analogous, with sums replacing integrals.

1. From the change of variables theorem for expected value,

$$E[r(X)E(Y | X)] = \int_S r(x)E(Y | X = x)g(x) dx = \int_S r(x) \left(\int_T yh(y | x) dy \right) g(x) dx \quad (4.7.6)$$

$$= \int_S \int_T r(x)yh(y | x)g(x) dy dx = \int_{S \times T} r(x)yf(x, y) d(x, y) = E[r(X)Y] \quad (4.7.7)$$

2. Suppose that $u_1 : S \rightarrow \mathbb{R}$ and $u_2 : S \rightarrow \mathbb{R}$ satisfy the condition in (b). Define $r : S \rightarrow \mathbb{R}$ by $r(x) = \mathbf{1}_{[u_1(x) > u_2(x)]}$. Then by assumption, $E[r(X)u_1(X)] = E[r(X)Y] = E[r(X)u_2(X)]$. But if $\mathbb{P}[u_1(X) > u_2(X)] > 0$ then $E[r(X)u_1(X)] > E[r(X)u_2(X)]$, a contradiction. Hence we must have $\mathbb{P}[u_1(X) > u_2(X)] = 0$ and by a symmetric argument, $\mathbb{P}[u_1(X) < u_2(X)] = 0$.

Two random variables that are equal with probability 1 are said to be equivalent. We often think of equivalent random variables as being essentially the same object, so the [fundamental property](#) above essentially characterizes $\mathbb{E}(Y | X)$. That is, we can think of $\mathbb{E}(Y | X)$ as any random variable that is a function of X and satisfies this property. Moreover the fundamental property can be used as a definition of conditional expected value, regardless of the type of the distribution of (X, Y) . If you are interested, read the more advanced treatment of conditional expected value.

Suppose that X is also real-valued. Recall that the best linear predictor of Y based on X was characterized by property (a), but with just two functions: $r(x) = 1$ and $r(x) = x$. Thus the characterization in the fundamental property is certainly reasonable, since (as we show below) $\mathbb{E}(Y | X)$ is the best predictor of Y among *all* functions of X , not just linear functions.

The [basic property](#) is also very useful for establishing other properties of conditional expected value. Our first consequence is the fact that Y and $\mathbb{E}(Y | X)$ have the same mean.

$$\mathbb{E}[\mathbb{E}(Y | X)] = \mathbb{E}(Y).$$

Proof

Let r be the constant function 1 in the [basic property](#).

Aside from the theoretical interest, [this theorem](#) is often a good way to compute $\mathbb{E}(Y)$ when we know the conditional distribution of Y given X . We say that we are computing the expected value of Y by *conditioning* on X .

For many basic properties of ordinary expected value, there are analogous results for conditional expected value. We start with two of the most important: every type of expected value must satisfy two critical properties: linearity and monotonicity. In the following two theorems, the random variables Y and Z are real-valued, and as before, X is a general random variable.

Linear Properties

1. $\mathbb{E}(Y + Z | X) = \mathbb{E}(Y | X) + \mathbb{E}(Z | X)$.
2. $\mathbb{E}(cY | X) = c\mathbb{E}(Y | X)$

Proof

1. Note that $\mathbb{E}(Y | X) + \mathbb{E}(Z | X)$ is a function of X . If $r : S \rightarrow \mathbb{R}$ then

$$\mathbb{E}(r(x) [\mathbb{E}(Y | X) + \mathbb{E}(Z | X)]) = \mathbb{E}[r(X)\mathbb{E}(Y | X)] + \mathbb{E}[r(X)\mathbb{E}(Z | X)] = \mathbb{E}[r(X)Y] + \mathbb{E}[r(X)Z] = \mathbb{E}[r(X)(Y + Z)] \quad (4.7.8)$$

Hence the result follows from the [basic property](#).

2. Note that $c\mathbb{E}(Y | X)$ is a function of X . If $r : S \rightarrow \mathbb{R}$ then

$$\mathbb{E}[r(X)c\mathbb{E}(Y | X)] = c\mathbb{E}[r(X)\mathbb{E}(Y | X)] = c\mathbb{E}[r(X)Y] = \mathbb{E}[r(X)(cY)] \quad (4.7.9)$$

Hence the result follows from the [basic property](#)

Part (a) is the additive property and part (b) is the scaling property. The scaling property will be significantly generalized below in (8).

Positive and Increasing Properties

1. If $Y \geq 0$ then $\mathbb{E}(Y | X) \geq 0$.
2. If $Y \leq Z$ then $\mathbb{E}(Y | X) \leq \mathbb{E}(Z | X)$.
3. $|\mathbb{E}(Y | X)| \leq \mathbb{E}(|Y| | X)$

Proof

1. This follows directly from the definition.
2. Note that if $Y \leq Z$ then $Y - Z \leq 0$ so by (a) and linearity,

$$\mathbb{E}(Y - Z | X) = \mathbb{E}(Y | X) - \mathbb{E}(Z | X) \geq 0 \quad (4.7.10)$$

3. Note that $-|Y| \leq Y \leq |Y|$ and hence by (b) and linearity, $-\mathbb{E}(|Y| | X) \leq \mathbb{E}(Y | X) \leq \mathbb{E}(|Y| | X)$.

Our next few properties relate to the idea that $\mathbb{E}(Y | X)$ is the expected value of Y given X . The first property is essentially a restatement of the [fundamental property](#).

If $r : S \rightarrow \mathbb{R}$, then $Y - \mathbb{E}(Y | X)$ and $r(X)$ are uncorrelated.

Proof

Note that $Y - \mathbb{E}(Y | X)$ has mean 0 by the [mean property](#). Hence, by the [basic property](#),

$$\text{cov}[Y - \mathbb{E}(Y | X), r(X)] = \mathbb{E}\{[Y - \mathbb{E}(Y | X)] r(X)\} = \mathbb{E}[Y r(X)] - \mathbb{E}[\mathbb{E}(Y | X) r(X)] = 0 \quad (4.7.11)$$

The next result states that any (deterministic) function of X acts like a constant in terms of the conditional expected value with respect to X .

If $s : S \rightarrow \mathbb{R}$ then

$$\mathbb{E}[s(X)Y | X] = s(X)\mathbb{E}(Y | X) \quad (4.7.12)$$

Proof

Note that $s(X)\mathbb{E}(Y | X)$ is a function of X . If $r : S \rightarrow \mathbb{R}$ then

$$\mathbb{E}[r(X)s(X)\mathbb{E}(Y | X)] = \mathbb{E}[r(X)s(X)Y] \quad (4.7.13)$$

So the result now follow from the [basic property](#).

The following rule generalizes theorem (8) and is sometimes referred to as the *substitution rule* for conditional expected value.

If $s : S \times T \rightarrow \mathbb{R}$ then

$$\mathbb{E}[s(X, Y) | X = x] = \mathbb{E}[s(x, Y) | X = x] \quad (4.7.14)$$

In particular, it follows from (8) that $\mathbb{E}[s(X) | X] = s(X)$. At the opposite extreme, we have the next result: If X and Y are independent, then knowledge of X gives no information about Y and so the conditional expected value with respect to X reduces to the ordinary (unconditional) expected value of Y .

If X and Y are independent then

$$\mathbb{E}(Y | X) = \mathbb{E}(Y) \quad (4.7.15)$$

Proof

Trivially, $\mathbb{E}(Y)$ is a (constant) function of X . If $r : S \rightarrow \mathbb{R}$ then $\mathbb{E}[\mathbb{E}(Y)r(X)] = \mathbb{E}(Y)\mathbb{E}[r(X)] = \mathbb{E}[Yr(X)]$, the last equality by independence. Hence the result follows from the [basic property](#).

Suppose now that Z is real-valued and that X and Y are random variables (all defined on the same probability space, of course). The following theorem gives a consistency condition of sorts. Iterated conditional expected values reduce to a single conditional expected value with respect to the minimum amount of information. For simplicity, we write $\mathbb{E}[Z | X, Y]$ rather than $\mathbb{E}[Z | (X, Y)]$.

Consistency

1. $\mathbb{E}[\mathbb{E}(Z | X, Y) | X] = \mathbb{E}(Z | X)$
2. $\mathbb{E}[\mathbb{E}(Z | X) | X, Y] = \mathbb{E}(Z | X)$

Proof

1. Suppose that X takes values in S and Y takes values in T , so that (X, Y) takes values in $S \times T$. By definition, $\mathbb{E}(Z | X)$ is a function of X . If $r : S \rightarrow \mathbb{R}$ then trivially r can be thought of as a function on $S \times T$ as well. Hence

$$\mathbb{E}[r(X)\mathbb{E}(Z | X)] = \mathbb{E}[r(X)Z] = \mathbb{E}[r(X)\mathbb{E}(Z | X, Y)] \quad (4.7.16)$$

It follows from the [basic property](#) that $\mathbb{E}[\mathbb{E}(Z | X, Y) | X] = \mathbb{E}(Z | X)$.

2. Note that since $\mathbb{E}(Z | X)$ is a function of X , it is trivially a function of (X, Y) . Hence from (8), $\mathbb{E}[\mathbb{E}(Z | X) | X, Y] = \mathbb{E}(Z | X)$.

Finally we show that $\mathbb{E}(Y | X)$ has the same covariance with X as does Y , not surprising since again, $\mathbb{E}(Y | X)$ behaves just like Y in its relations with X .

$$\text{cov}[X, \mathbb{E}(Y | X)] = \text{cov}(X, Y).$$

Proof

$\text{cov}[X, \mathbb{E}(Y | X)] = \mathbb{E}[X\mathbb{E}(Y | X)] - \mathbb{E}(X)\mathbb{E}[\mathbb{E}(Y | X)]$. But $\mathbb{E}[X\mathbb{E}(Y | X)] = \mathbb{E}(XY)$ by [basic property](#), and $\mathbb{E}[\mathbb{E}(Y | X)] = \mathbb{E}(Y)$ by the [mean property](#). Hence $\text{cov}[X, \mathbb{E}(Y | X)] = \mathbb{E}(XY) - \mathbb{E}(X)\mathbb{E}(Y) = \text{cov}(X, Y)$.

Conditional Probability

The conditional probability of an event A , given random variable X (as above), can be defined as a special case of the conditional expected value. As usual, let $\mathbf{1}_A$ denote the indicator random variable of A .

If A is an event, defined

$$\mathbb{P}(A | X) = \mathbb{E}(\mathbf{1}_A | X) \quad (4.7.17)$$

Here is the fundamental property for conditional probability:

The fundamental property

1. $\mathbb{E}[r(X)\mathbb{P}(A | X)] = \mathbb{E}[r(X)\mathbf{1}_A]$ for every function $r : S \rightarrow \mathbb{R}$.
2. If $u : S \rightarrow \mathbb{R}$ and $u(X)$ satisfies $\mathbb{E}[r(X)u(X)] = \mathbb{E}[r(X)\mathbf{1}_A]$ for every function $r : S \rightarrow \mathbb{R}$, then $\mathbb{P}[u(X) = \mathbb{P}(A | X)] = 1$.

For example, suppose that X has a discrete distribution on a countable set S with probability density function g . Then (a) becomes

$$\sum_{x \in S} r(x)\mathbb{P}(A | X = x)g(x) = \sum_{x \in S} r(x)\mathbb{P}(A, X = x) \quad (4.7.18)$$

But this is obvious since $\mathbb{P}(A | X = x) = \mathbb{P}(A, X = x) / \mathbb{P}(X = x)$ and $g(x) = \mathbb{P}(X = x)$. Similarly, if X has a continuous distribution on $S \subseteq \mathbb{R}^n$ then (a) states that

$$\mathbb{E}[r(X)\mathbf{1}_A] = \int_S r(x)\mathbb{P}(A | X = x)g(x) dx \quad (4.7.19)$$

The properties above for conditional expected value, of course, have special cases for conditional probability.

$$\mathbb{P}(A) = \mathbb{E}[\mathbb{P}(A | X)].$$

Proof

This is a direct result of the [mean property](#), since $\mathbb{E}(\mathbf{1}_A) = \mathbb{P}(A)$.

Again, the result in the previous exercise is often a good way to compute $\mathbb{P}(A)$ when we know the conditional probability of A given X . We say that we are computing the probability of A by *conditioning* on X . This is a very compact and elegant version of the conditioning result given first in the section on Conditional Probability in the

chapter on Probability Spaces and later in the section on Discrete Distributions in the Chapter on Distributions.

The following result gives the conditional version of the axioms of probability.

Axioms of probability

1. $\mathbb{P}(A | X) \geq 0$ for every event A .
2. $\mathbb{P}(\Omega | X) = 1$
3. If $\{A_i : i \in I\}$ is a countable collection of disjoint events then $\mathbb{P}(\bigcup_{i \in I} A_i | X) = \sum_{i \in I} \mathbb{P}(A_i | X)$.

Details

There are some technical issues involving the countable additivity property (c). The conditional probabilities are random variables, and so for a given collection $\{A_i : i \in I\}$, the left and right sides are the same with probability 1. We will return to this point in the more advanced section on conditional expected value

From the last result, it follows that other standard probability rules hold for conditional probability given X . These results include

- the complement rule
- the increasing property
- Boole's inequality
- Bonferroni's inequality
- the inclusion-exclusion laws

The Best Predictor

The next result shows that, of all functions of X , $\mathbb{E}(Y | X)$ is closest to Y , in the sense of mean square error. This is fundamentally important in statistical problems where the *predictor vector* X can be observed but not the *response variable* Y . In this subsection and the next, we assume that the real-valued random variables have finite variance.

If $u : S \rightarrow \mathbb{R}$, then

1. $\mathbb{E}([\mathbb{E}(Y | X) - Y]^2) \leq \mathbb{E}([u(X) - Y]^2)$
2. Equality holds in (a) if and only if $u(X) = \mathbb{E}(Y | X)$ with probability 1.

Proof

1. Note that

$$\mathbb{E}([Y - u(X)]^2) = \mathbb{E}([Y - \mathbb{E}(Y | X) + \mathbb{E}(Y | X) - u(X)]^2) \quad (4.7.20)$$

$$= \mathbb{E}([Y - \mathbb{E}(Y | X)]^2) + 2\mathbb{E}([Y - \mathbb{E}(Y | X)][\mathbb{E}(Y | X) - u(X)]) + \mathbb{E}([\mathbb{E}(Y | X) - u(X)]^2) \quad (4.7.21)$$

But $Y - \mathbb{E}(Y | X)$ has mean 0, so the middle term on the right is $2\text{cov}[Y - \mathbb{E}(Y | X), \mathbb{E}(Y | X) - u(X)]$. Moreover, $\mathbb{E}(Y | X) - u(X)$ is a function of X and hence is uncorrelated with $Y - \mathbb{E}(Y | X)$ by the general [uncorrelated property](#). Hence the middle term is 0, so

$$\mathbb{E}([Y - u(X)]^2) = \mathbb{E}([Y - \mathbb{E}(Y | X)]^2) + \mathbb{E}([\mathbb{E}(Y | X) - u(X)]^2) \quad (4.7.22)$$

and therefore $\mathbb{E}([Y - \mathbb{E}(Y | X)]^2) \leq \mathbb{E}([Y - u(X)]^2)$.

2. Equality holds if and only if $\mathbb{E}([\mathbb{E}(Y | X) - u(X)]^2) = 0$, if and only if $\mathbb{P}[u(X) = \mathbb{E}(Y | X)] = 1$.

Suppose now that X is real-valued. In the section on covariance and correlation, we found that the best *linear* predictor of Y given X is

$$L(Y | X) = \mathbb{E}(Y) + \frac{\text{cov}(X, Y)}{\text{var}(X)}[X - \mathbb{E}(X)] \quad (4.7.23)$$

On the other hand, $\mathbb{E}(Y | X)$ is the best predictor of Y among *all* functions of X . It follows that if $\mathbb{E}(Y | X)$ happens to be a linear function of X then it must be the case that $\mathbb{E}(Y | X) = L(Y | X)$. However, we will give a direct proof also:

If $\mathbb{E}(Y | X) = a + bX$ for constants a and b then $\mathbb{E}(Y | X) = L(Y | X)$; that is,

1. $b = \text{cov}(X, Y) / \text{var}(X)$
2. $a = \mathbb{E}(Y) - \mathbb{E}(X)\text{cov}(X, Y) / \text{var}(X)$

Proof

First, $\mathbb{E}(Y) = \mathbb{E}[\mathbb{E}(Y | X)] = a + b\mathbb{E}(X)$, so $a = \mathbb{E}(Y) - b\mathbb{E}(X)$. Next, $\text{cov}(X, Y) = \text{cov}[X\mathbb{E}(Y | X)] = \text{cov}(X, a + bX) = b\text{var}(X)$ and therefore $b = \text{cov}(X, Y) / \text{var}(X)$.

Conditional Variance

The conditional variance of Y given X is defined like the ordinary variance, but with all expected values conditioned on X .

The *conditional variance* of Y given X is defined as

$$\text{var}(Y | X) = \mathbb{E}([Y - \mathbb{E}(Y | X)]^2 | X) \quad (4.7.24)$$

Thus, $\text{var}(Y | X)$ is a function of X , and in particular, is a random variable. Our first result is a computational formula that is analogous to the one for standard variance—the variance is the mean of the square minus the square of the mean, but now with all expected values conditioned on X :

$$\text{var}(Y | X) = \mathbb{E}(Y^2 | X) - [\mathbb{E}(Y | X)]^2.$$

Proof

Expanding the square in the definition and using basic properties of conditional expectation, we have

$$\text{var}(Y | X) = \mathbb{E} \left(Y^2 - 2Y\mathbb{E}(Y | X) + [\mathbb{E}(Y | X)]^2 \mid X \right) = \mathbb{E}(Y^2 | X) - 2\mathbb{E}[Y\mathbb{E}(Y | X) | X] + \mathbb{E}([\mathbb{E}(Y | X)]^2 | X) \quad (4.7.25)$$

$$= \mathbb{E}(Y^2 | X) - 2\mathbb{E}(Y | X)\mathbb{E}(Y | X) + [\mathbb{E}(Y | X)]^2 = \mathbb{E}(Y^2 | X) - [\mathbb{E}(Y | X)]^2 \quad (4.7.26)$$

Our next result shows how to compute the ordinary variance of Y by *conditioning on X* .

$$\text{var}(Y) = \mathbb{E}[\text{var}(Y | X)] + \text{var}[\mathbb{E}(Y | X)].$$

Proof

From the previous theorem and properties of conditional expected value we have $\mathbb{E}[\text{var}(Y | X)] = \mathbb{E}(Y^2) - \mathbb{E}([\mathbb{E}(Y | X)]^2)$. But $\mathbb{E}(Y^2) = \text{var}(Y) + [\mathbb{E}(Y)]^2$

and similarly, $\mathbb{E}([\mathbb{E}(Y | X)]^2) = \text{var}[\mathbb{E}(Y | X)] + (\mathbb{E}[\mathbb{E}(Y | X)])^2$. But also, $\mathbb{E}[\mathbb{E}(Y | X)] = \mathbb{E}(Y)$ so substituting we get $\mathbb{E}[\text{var}(Y | X)] = \text{var}(Y) - \text{var}[\mathbb{E}(Y | X)]$.

Thus, the variance of Y is the expected conditional variance plus the variance of the conditional expected value. This result is often a good way to compute $\text{var}(Y)$ when we know the conditional distribution of Y given X . With the help of (21) we can give a formula for the mean square error when $\mathbb{E}(Y | X)$ is used a predictor of Y .

Mean square error

$$\mathbb{E}([Y - \mathbb{E}(Y | X)]^2) = \text{var}(Y) - \text{var}[\mathbb{E}(Y | X)] \quad (4.7.27)$$

Proof

From the definition of [conditional variance](#), and using [mean property](#) and [variance formula](#) we have

$$\mathbb{E}([Y - \mathbb{E}(Y | X)]^2) = \mathbb{E}[\text{var}(Y | X)] = \text{var}(Y) - \text{var}[\mathbb{E}(Y | X)] \quad (4.7.28)$$

Let us return to the study of predictors of the real-valued random variable Y , and compare the three predictors we have studied in terms of mean square error.

Suppose that Y is a real-valued random variable.

1. The best *constant predictor* of Y is $\mathbb{E}(Y)$ with mean square error $\text{var}(Y)$.
2. If X is another real-valued random variable, then the best *linear predictor* of Y given X is

$$L(Y | X) = \mathbb{E}(Y) + \frac{\text{cov}(X, Y)}{\text{var}(X)}[X - \mathbb{E}(X)] \quad (4.7.29)$$

with mean square error $\text{var}(Y)[1 - \text{cor}^2(X, Y)]$.

3. If X is a general random variable, then the best *overall predictor* of Y given X is $\mathbb{E}(Y | X)$ with mean square error $\text{var}(Y) - \text{var}[\mathbb{E}(Y | X)]$.

Conditional Covariance

Suppose that Y and Z are real-valued random variables, and that X is a general random variable, all defined on our underlying probability space. Analogous to variance, the conditional covariance of Y and Z given X is defined like the ordinary covariance, but with all expected values conditioned on X .

The *conditional covariance* of Y and Z given X is defined as

$$\text{cov}(Y, Z | X) = \mathbb{E}([Y - \mathbb{E}(Y | X)][Z - \mathbb{E}(Z | X)] | X) \quad (4.7.30)$$

Thus, $\text{cov}(Y, Z | X)$ is a function of X , and in particular, is a random variable. Our first result is a computational formula that is analogous to the one for standard covariance—the covariance is the mean of the product minus the product of the means, but now with all expected values conditioned on X :

$$\text{cov}(Y, Z | X) = \mathbb{E}(YZ | X) - \mathbb{E}(Y | X)\mathbb{E}(Z | X).$$

Proof

Expanding the product in the definition and using basic properties of conditional expectation, we have

$$\begin{aligned} \text{cov}(Y, Z | X) &= \mathbb{E} \left(YZ - Y\mathbb{E}(Z | X) - Z\mathbb{E}(Y | X) + \mathbb{E}(Y | X)\mathbb{E}(Z | X) \mid X \right) = \mathbb{E}(YZ | X) - \mathbb{E}[Y\mathbb{E}(Z | X) | X] - \mathbb{E}[Z\mathbb{E}(Y | X) | X] \\ &\quad + \mathbb{E}[\mathbb{E}(Y | X)\mathbb{E}(Z | X) | X] \end{aligned} \quad (4.7.31)$$

$$= \mathbb{E}(YZ | X) - \mathbb{E}(Y | X)\mathbb{E}(Z | X) - \mathbb{E}(Y | X)\mathbb{E}(Z | X) + \mathbb{E}(Y | X)\mathbb{E}(Z | X) = \mathbb{E}(YZ | X) - \mathbb{E}(Y | X)\mathbb{E}(Z | X) \quad (4.7.32)$$

Our next result shows how to compute the ordinary covariance of Y and Z by *conditioning on X* .

$$\text{cov}(Y, Z) = \mathbb{E}[\text{cov}(Y, Z | X)] + \text{cov}[\mathbb{E}(Y | X), \mathbb{E}(Z | X)].$$

Proof

From (25) and properties of conditional expected value we have

$$\mathbb{E}[\text{cov}(Y, Z | X)] = \mathbb{E}(YZ) - \mathbb{E}[\mathbb{E}(Y | X)\mathbb{E}(Z | X)] \quad (4.7.33)$$

But $\mathbb{E}(YZ) = \text{cov}(Y, Z) + \mathbb{E}(Y)\mathbb{E}(Z)$ and similarly,

$$\mathbb{E}[\mathbb{E}(Y | X)\mathbb{E}(Z | X)] = \text{cov}[\mathbb{E}(Y | X), \mathbb{E}(Z | X)] + \mathbb{E}[\mathbb{E}(Y | X)]\mathbb{E}[\mathbb{E}(Z | X)] \quad (4.7.34)$$

But also, $\mathbb{E}[\mathbb{E}(Y | X)] = \mathbb{E}(Y)$ and $\mathbb{E}[\mathbb{E}(Z | X)] = \mathbb{E}(Z)$ so substituting we get

$$\mathbb{E}[\text{cov}(Y, Z | X)] = \text{cov}(Y, Z) - \text{cov}[\mathbb{E}(Y | X), \mathbb{E}(Z | X)] \quad (4.7.35)$$

Thus, the covariance of Y and Z is the expected conditional covariance plus the covariance of the conditional expected values. This result is often a good way to compute $\text{cov}(Y, Z)$ when we know the conditional distribution of (Y, Z) given X .

Examples and Applications

As always, be sure to try the proofs and computations yourself before reading the ones in the text.

Simple Continuous Distributions

Suppose that (X, Y) has probability density function f defined by $f(x, y) = x + y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.

1. Find $L(Y | X)$.
2. Find $\mathbb{E}(Y | X)$.
3. Graph $L(Y | X = x)$ and $\mathbb{E}(Y | X = x)$ as functions of x , on the same axes.
4. Find $\text{var}(Y)$.
5. Find $\text{var}(Y) [1 - \text{cor}^2(X, Y)]$.
6. Find $\text{var}(Y) - \text{var}[\mathbb{E}(Y | X)]$.

Answer

1. $\frac{7}{11} - \frac{1}{11}X$
2. $\frac{3X+2}{6X+3}$
4. $\frac{11}{144} = 0.0764$
5. $\frac{5}{66} = 0.0758$
6. $\frac{1}{12} - \frac{1}{144} \ln 3 = 0.0757$

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 2(x + y)$ for $0 \leq x \leq y \leq 1$.

1. Find $L(Y | X)$.
2. Find $\mathbb{E}(Y | X)$.
3. Graph $L(Y | X = x)$ and $\mathbb{E}(Y | X = x)$ as functions of x , on the same axes.
4. Find $\text{var}(Y)$.
5. Find $\text{var}(Y) [1 - \text{cor}^2(X, Y)]$.
6. Find $\text{var}(Y) - \text{var}[\mathbb{E}(Y | X)]$.

Answer

1. $\frac{26}{43} + \frac{15}{43}X$
2. $\frac{5X^2+5X+2}{9X+3}$
4. $\frac{3}{80} = 0.0375$
5. $\frac{13}{430} = 0.0302$
6. $\frac{1837}{21870} - \frac{512}{6561} \ln(2) = 0.0299$

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 6x^2y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$.

1. Find $L(Y | X)$.
2. Find $\mathbb{E}(Y | X)$.
3. Graph $L(Y | X = x)$ and $\mathbb{E}(Y | X = x)$ as functions of x , on the same axes.
4. Find $\text{var}(Y)$.
5. Find $\text{var}(Y) [1 - \text{cor}^2(X, Y)]$.
6. Find $\text{var}(Y) - \text{var}[\mathbb{E}(Y | X)]$.

Answer

Note that X and Y are independent.

1. $\frac{2}{3}$
2. $\frac{2}{3}$
4. $\frac{1}{18}$
5. $\frac{1}{18}$
6. $\frac{1}{18}$

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 15x^2y$ for $0 \leq x \leq y \leq 1$.

1. Find $L(Y | X)$.
2. Find $\mathbb{E}(Y | X)$.

3. Graph $L(Y | X = x)$ and $\mathbb{E}(Y | X = x)$ as functions of x , on the same axes.
4. Find $\text{var}(Y)$.
5. Find $\text{var}(Y) [1 - \text{cor}^2(X, Y)]$.
6. Find $\text{var}(Y) - \text{var}[\mathbb{E}(Y | X)]$.

Answer

1. $\frac{30}{51} + \frac{20}{51}X$
2. $\frac{2(X^2+X+1)}{3(X+1)}$
4. $\frac{5}{252} = 0.0198$
5. $\frac{5}{357} = 0.0140$
6. $\frac{292}{63} - \frac{20}{3}\ln(2) = 0.0139$

Exercises on Basic Properties

Suppose that X , Y , and Z are real-valued random variables with $\mathbb{E}(Y | X) = X^3$ and $\mathbb{E}(Z | X) = \frac{1}{1+X^2}$. Find $\mathbb{E}(Y e^X - Z \sin X | X)$.

Answer

$$X^3 e^X - \frac{\sin X}{1+X^2}$$

Uniform Distributions

As usual, continuous uniform distributions can give us some geometric insight.

Recall first that for $n \in \mathbb{N}_+$, the standard measure on \mathbb{R}^n is

$$\lambda_n(A) = \int_A 1 dx, \quad A \subseteq \mathbb{R}^n \quad (4.7.36)$$

In particular, $\lambda_1(A)$ is the length of $A \subseteq \mathbb{R}$, $\lambda_2(A)$ is the area of $A \subseteq \mathbb{R}^2$, and $\lambda_3(A)$ is the volume of $A \subseteq \mathbb{R}^3$.

Details

Technically λ_n is Lebesgue measure on the measurable subsets of \mathbb{R}^n . The integral representation is valid for the types of sets that occur in applications. In the discussion below, all subsets are assumed to be measurable.

With our usual setup, suppose that X takes values in $S \subseteq \mathbb{R}^n$, Y takes values in $T \subseteq \mathbb{R}$, and that (X, Y) is uniformly distributed on $R \subseteq S \times T \subseteq \mathbb{R}^{n+1}$. So $0 < \lambda_{n+1}(R) < \infty$, and the joint probability density function f of (X, Y) is given by $f(x, y) = 1/\lambda_{n+1}(R)$ for $(x, y) \in R$. Recall that uniform distributions, whether discrete or continuous, always have constant densities. Finally, recall that the cross section of R at $x \in S$ is $T_x = \{y \in T : (x, y) \in R\}$.

In the setting above, suppose that T_x is a bounded interval with midpoint $m(x)$ and length $l(x)$ for each $x \in S$. Then

1. $\mathbb{E}(Y | X) = m(X)$
2. $\text{var}(Y | X) = \frac{1}{12}l^2(X)$

Proof

This follows immediately from the fact that the conditional distribution of Y given $X = x$ is uniformly distributed on T_x for each $x \in S$.

So in particular, the regression curve $x \mapsto \mathbb{E}(Y | X = x)$ follows the midpoints of the cross-sectional intervals.

In each case below, suppose that (X, Y) is uniformly distributed on the give region. Find $\mathbb{E}(Y | X)$ and $\text{var}(Y | X)$

1. The rectangular region $R = [a, b] \times [c, d]$ where $a < b$ and $c < d$.
2. The triangular region $T = \{(x, y) \in \mathbb{R}^2 : -a \leq x \leq y \leq a\}$ where $a > 0$.
3. The circular region $C = \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 \leq r\}$ where $r > 0$.

Answer

1. $\mathbb{E}(Y | X) = \frac{1}{2}(c+d)$, $\text{var}(Y | X) = \frac{1}{12}(d-c)^2$. Note that X and Y are independent.
2. $\mathbb{E}(Y | X) = \frac{1}{2}(a+X)$, $\text{var}(Y | X) = \frac{1}{12}(a-X)^2$
3. $\mathbb{E}(Y | X) = 0$, $\text{var}(Y | X) = 4(r^2 - X^2)$

In the bivariate uniform experiment, select each of the following regions. In each case, run the simulation 2000 times and note the relationship between the cloud of points and the graph of the regression function.

1. square
2. triangle
3. circle

Suppose that X is uniformly distributed on the interval $(0, 1)$, and that given X , random variable Y is uniformly distributed on $(0, X)$. Find each of the following:

1. $\mathbb{E}(Y | X)$
2. $\mathbb{E}(Y)$
3. $\text{var}(Y | X)$
4. $\text{var}(Y)$

Answer

1. $\frac{1}{2}X$
2. $\frac{1}{4}$
3. $\frac{1}{12}X^2$
4. $\frac{7}{144}$

The Hypergeometric Distribution

Suppose that a population consists of m objects, and that each object is one of three types. There are a objects of type 1, b objects of type 2, and $m - a - b$ objects of type 0. The parameters a and b are positive integers with $a + b < m$. We sample n objects from the population at random, and without replacement, where $n \in \{0, 1, \dots, m\}$. Denote the number of type 1 and 2 objects in the sample by X and Y , so that the number of type 0 objects in the sample is $n - X - Y$. In the chapter on Distributions, we showed that the joint, marginal, and conditional distributions of X and Y are all hypergeometric—only the parameters change. Here is the relevant result for this section:

In the setting above,

1. $\mathbb{E}(Y | X) = \frac{b}{m-a}(n - X)$
2. $\text{var}(Y | X) = \frac{b(m-a-b)}{(m-a)^2(m-a-1)}(n - X)(m - a - n + X)$
3. $\mathbb{E}([Y - \mathbb{E}(Y | X)]^2) = \frac{n(m-n)b(m-a-b)}{m(m-1)(m-a)}$

Proof

Recall that (X, Y) has the (multivariate) hypergeometric distribution with parameters m, a, b , and n . Marginally, X has the hypergeometric distribution with parameters m, a , and n , and Y has the hypergeometric distribution with parameters m, b , and n . Given $X = x \in \{0, 1, \dots, n\}$, the remaining $n - x$ objects are chosen at random from a population of $m - a$ objects, of which b are type 2 and $m - a - b$ are type 0. Hence, the conditional distribution of Y given $X = x$ is hypergeometric with parameters $m - a, b$, and $n - x$. Parts (a) and (b) then follow from the standard formulas for the mean and variance of the hypergeometric distribution, as functions of the parameters. Part (c) is the mean square error, and in this case can be computed most easily as

$$\text{var}(Y) - \text{var}[\mathbb{E}(Y | X)] = \text{var}(Y) - \left(\frac{b}{m-a}\right)^2 \text{var}(X) = n \frac{b}{m} \frac{m-b}{m} \frac{m-n}{m-1} - \left(\frac{b}{m-a}\right)^2 n \frac{a}{m} \frac{m-a}{m} \frac{m-n}{m-1} \quad (4.7.37)$$

Simplifying gives the result.

Note that $\mathbb{E}(Y | X)$ is a linear function of X and hence $\mathbb{E}(Y | X) = L(Y | X)$.

In a collection of 120 objects, 50 are classified as *good*, 40 as *fair* and 30 as *poor*. A sample of 20 objects is selected at random and without replacement. Let X denote the number of good objects in the sample and Y the number of poor objects in the sample. Find each of the following:

1. $\mathbb{E}(Y | X)$
2. $\text{var}(Y | X)$
3. The predicted value of Y given $X = 8$

Answer

1. $\mathbb{E}(Y | X) = \frac{80}{7} - \frac{4}{7}X$
2. $\text{var}(Y | X) = \frac{4}{1127}(20 - X)(50 + X)$
3. $\frac{48}{7}$

The Multinomial Trials Model

Suppose that we have a sequence of n independent trials, and that each trial results in one of three outcomes, denoted 0, 1, and 2. On each trial, the probability of outcome 1 is p , the probability of outcome 2 is q , so that the probability of outcome 0 is $1 - p - q$. The parameters $p, q \in (0, 1)$ with $p + q < 1$, and of course $n \in \mathbb{N}_+$. Let X denote the number of trials that resulted in outcome 1, Y the number of trials that resulted in outcome 2, so that $n - X - Y$ is the number of trials that resulted in outcome 0. In the chapter on Distributions, we showed that the joint, marginal, and conditional distributions of X and Y are all multinomial—only the parameters change. Here is the relevant result for this section:

In the setting above,

1. $\mathbb{E}(Y | X) = \frac{q}{1-p}(n - X)$
2. $\text{var}(Y | X) = \frac{q(1-p-q)}{(1-p)^2}(n - X)$
3. $\mathbb{E}([Y - \mathbb{E}(Y | X)]^2) = \frac{q(1-p-q)}{1-p}n$

Proof

Recall that (X, Y) has the multinomial distribution with parameters n, p , and q . Marginally, X has the binomial distribution with parameters n and p , and Y has the binomial distribution with parameters n and q . Given $X = x \in \{0, 1, \dots, n\}$, the remaining $n - x$ trials are independent, but with just two outcomes: outcome 2 occurs with probability $q/(1 - p)$ and outcome 0 occurs with probability $1 - q/(1 - p)$. (These are the conditional probabilities of outcomes 2 and 0, respectively, given that outcome 1 did not occur.) Hence the conditional distribution of Y given $X = x$ is binomial with parameters $n - x$ and $q/(1 - p)$. Parts (a) and (b) then follow from the standard formulas for the mean and variance of the binomial distribution, as functions of the parameters. Part (c) is the mean square error and in this case can be computed most easily from

$$\mathbb{E}[\text{var}(Y | X)] = \frac{q(1-p-q)}{(1-p)^2}[n - \mathbb{E}(X)] = \frac{q(1-p-q)}{(1-p)^2}(n - np) = \frac{q(1-p-q)}{1-p}n \quad (4.7.38)$$

Note again that $\mathbb{E}(Y | X)$ is a linear function of X and hence $\mathbb{E}(Y | X) = L(Y | X)$.

Suppose that a fair, 12-sided die is thrown 50 times. Let X denote the number of throws that resulted in a number from 1 to 5, and Y the number of throws that resulted in a number from 6 to 9. Find each of the following:

1. $\mathbb{E}(Y | X)$
2. $\text{var}(Y | X)$
3. The predicted value of Y given $X = 20$

Answer

1. $\mathbb{E}(Y | X) = \frac{4}{7}(50 - X)$
2. $\text{var}(Y | X) = \frac{12}{49}(50 - X)$
3. $\frac{120}{7}$

The Poisson Distribution

Recall that the *Poisson distribution*, named for Simeon Poisson, is widely used to model the number of “random points” in a region of time or space, under certain ideal conditions. The Poisson distribution is studied in more detail in the chapter on the Poisson Process. The Poisson distribution with parameter $r \in (0, \infty)$ has probability density function f defined by

$$f(x) = e^{-r} \frac{r^x}{x!}, \quad x \in \mathbb{N} \quad (4.7.39)$$

The parameter r is the mean and variance of the distribution.

Suppose that X and Y are independent random variables, and that X has the Poisson distribution with parameter $a \in (0, \infty)$ and Y has the Poisson distribution with parameter $b \in (0, \infty)$. Let $N = X + Y$. Then

1. $\mathbb{E}(X | N) = \frac{a}{a+b} N$
2. $\text{var}(X | N) = \frac{ab}{(a+b)^2} N$
3. $\mathbb{E}([X - \mathbb{E}(X | N)]^2) = \frac{ab}{a+b}$

Proof

We have shown before that the distribution of N is also Poisson, with parameter $a + b$, and that the conditional distribution of X given $N = n \in \mathbb{N}$ is binomial with parameters n and $a/(a+b)$. Hence parts (a) and (b) follow from the standard formulas for the mean and variance of the binomial distribution, as functions of the parameters. Part (c) is the mean square error, and in this case can be computed most easily as

$$\mathbb{E}[\text{var}(X | N)] = \frac{ab}{(a+b)^2} \mathbb{E}(N) = \frac{ab}{(a+b)^2} (a+b) = \frac{ab}{a+b} \quad (4.7.40)$$

Once again, $\mathbb{E}(X | N)$ is a linear function of N and so $\mathbb{E}(X | N) = L(X | N)$. If we reverse the roles of the variables, the conditional expected value is trivial from our basic properties:

$$\mathbb{E}(N | X) = \mathbb{E}(X + Y | X) = X + b \quad (4.7.41)$$

Coins and Dice

A pair of fair dice are thrown, and the scores (X_1, X_2) recorded. Let $Y = X_1 + X_2$ denote the sum of the scores and $U = \min\{X_1, X_2\}$ the minimum score. Find each of the following:

1. $\mathbb{E}(Y | X_1)$
2. $\mathbb{E}(U | X_1)$
3. $\mathbb{E}(Y | U)$
4. $\mathbb{E}(X_2 | X_1)$

Answer

1. $\frac{7}{2} + X_1$

2. x	1	2	3	4	5	6
$\mathbb{E}(U X_1 = x)$	1	$\frac{11}{6}$	$\frac{5}{2}$	3	$\frac{10}{3}$	$\frac{7}{2}$

3. u	1	2	3	4	5	6
$\mathbb{E}(Y U = u)$	$\frac{52}{11}$	$\frac{56}{9}$	$\frac{54}{7}$	$\frac{46}{5}$	$\frac{32}{3}$	12

4. $\frac{7}{2}$

A box contains 10 coins, labeled 0 to 9. The probability of heads for coin i is $\frac{i}{9}$. A coin is chosen at random from the box and tossed. Find the probability of heads.

Answer

$$\frac{1}{2}$$

This problem is an example of Laplace's rule of succession, named for Pierre Simon Laplace.

Random Sums of Random Variables

Suppose that $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of independent and identically distributed real-valued random variables. We will denote the common mean, variance, and moment generating function, respectively, by $\mu = \mathbb{E}(X_i)$, $\sigma^2 = \text{var}(X_i)$, and $G(t) = \mathbb{E}(e^{tX_i})$. Let

$$Y_n = \sum_{i=1}^n X_i, \quad n \in \mathbb{N} \quad (4.7.42)$$

so that (Y_0, Y_1, \dots) is the partial sum process associated with \mathbf{X} . Suppose now that N is a random variable taking values in \mathbb{N} , independent of \mathbf{X} . Then

$$Y_N = \sum_{i=1}^N X_i \quad (4.7.43)$$

is a random sum of random variables; the terms in the sum are random, and the number of terms is random. This type of variable occurs in many different contexts. For example, N might represent the number of customers who enter a store in a given period of time, and X_i the amount spent by the customer i , so that Y_N is the total revenue of the store during the period.

The conditional and ordinary expected value of Y_N are

1. $\mathbb{E}(Y_N | N) = N\mu$
2. $\mathbb{E}(Y_N) = \mathbb{E}(N)\mu$

Proof

1. Using the substitution rule and the independence of N and \mathbf{X} we have

$$\mathbb{E}(Y_N | N = n) = \mathbb{E}(Y_n | N = n) = \mathbb{E}(Y_n) = \sum_{i=1}^n \mathbb{E}(X_i) = n\mu \quad (4.7.44)$$

so $\mathbb{E}(Y_N | N) = N\mu$.

2. From (a) and conditioning, $\mathbb{E}(Y_N) = \mathbb{E}[\mathbb{E}(Y_N | N)] = \mathbb{E}(N\mu) = \mathbb{E}(N)\mu$.

Wald's equation, named for Abraham Wald, is a generalization of the previous result to the case where N is not necessarily independent of \mathbf{X} , but rather is a *stopping time* for \mathbf{X} . Roughly, this means that the event $N = n$ depends only (X_1, X_2, \dots, X_n) . Wald's equation is discussed in the chapter on Random Samples. An elegant proof of and Wald's equation is given in the chapter on Martingales. The advanced section on stopping times is in the chapter on Probability Measures.

The conditional and ordinary variance of Y_N are

1. $\text{var}(Y_N | N) = N\sigma^2$
2. $\text{var}(Y_N) = \mathbb{E}(N)\sigma^2 + \text{var}(N)\mu^2$

Proof

1. Using the substitution rule, the independence of N and \mathbf{X} , and the fact that \mathbf{X} is an IID sequence, we have

$$\text{var}(Y_N | N = n) = \text{var}(Y_n | N = n) = \text{var}(Y_n) = \sum_{i=1}^n \text{var}(X_i) = n\sigma^2 \quad (4.7.45)$$

so $\text{var}(Y_N | N) = N\sigma^2$.

2. From (a) and the previous result,

$$\text{var}(Y_N) = \mathbb{E}[\text{var}(Y_N | N)] + \text{var}[\mathbb{E}(Y_N | N)] = \mathbb{E}(\sigma^2 N) + \text{var}(\mu N) = \mathbb{E}(N)\sigma^2 + \mu^2 \text{var}(N) \quad (4.7.46)$$

Let H denote the probability generating function of N . The conditional and ordinary moment generating function of Y_N are

1. $\mathbb{E}(e^{tY_N} | N) = [G(t)]^N$
2. $\mathbb{E}(e^{tY_N}) = H(G(t))$

Proof

1. Using the substitution rule, the independence of N and \mathbf{X} , and the fact that \mathbf{X} is an IID sequence, we have

$$\mathbb{E}(e^{tY_N} | N = n) = \mathbb{E}(e^{tY_n} | N = n) = \mathbb{E}(e^{tY_n}) = [G(t)]^n \quad (4.7.47)$$

(Recall that the MGF of the sum of independent variables is the product of the individual MGFs.)

2. From (a) and conditioning, $\mathbb{E}(e^{tY_N}) = \mathbb{E}[\mathbb{E}(e^{tY_N} | N)] = \mathbb{E}(G(t)^N) = H(G(t))$.

Thus the moment generating function of Y_N is $H \circ G$, the composition of the probability generating function of N with the common moment generating function of \mathbf{X} , a simple and elegant result.

In the die-coin experiment, a fair die is rolled and then a fair coin is tossed the number of times showing on the die. Let N denote the die score and Y the number of heads. Find each of the following:

1. The conditional distribution of Y given N .
2. $\mathbb{E}(Y | N)$
3. $\text{var}(Y | N)$
4. $\mathbb{E}(Y_i)$
5. $\text{var}(Y)$

Answer

1. Binomial with parameters N and $p = \frac{1}{2}$
2. $\frac{1}{2}N$
3. $\frac{1}{4}N$
4. $\frac{7}{4}$
5. $\frac{7}{3}$

Run the die-coin experiment 1000 times and compare the empirical mean and standard deviation to the distribution mean and standard deviation.

The number of customers entering a store in a given hour is a random variable with mean 20 and standard deviation 3. Each customer, independently of the others, spends a random amount of money with mean \$50 and standard deviation \$5. Find the mean and standard deviation of the amount of money spent during the hour.

Answer

1. \$1000
2. \$30.82

A coin has a random probability of heads V and is tossed a random number of times N . Suppose that V is uniformly distributed on $[0, 1]$; N has the Poisson distribution with parameter $a > 0$; and V and N are independent. Let Y denote the number of heads. Compute the following:

1. $\mathbb{E}(Y \mid N, V)$
2. $\mathbb{E}(Y \mid N)$
3. $\mathbb{E}(Y \mid V)$
4. $\mathbb{E}(Y)$
5. $\text{var}(Y \mid N, V)$
6. $\text{var}(Y)$

Answer

1. NV
2. $\frac{1}{2}N$
3. aV
4. $\frac{1}{2}a$
5. $NV(1 - V)$
6. $\frac{1}{12}a^2 + \frac{1}{2}a$

Mixtures of Distributions

Suppose that $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of real-valued random variables. Denote the mean, variance, and moment generating function of X_i by $\mu_i = \mathbb{E}(X_i)$, $\sigma_i^2 = \text{var}(X_i)$, and $M_i(t) = \mathbb{E}(e^{tX_i})$, for $i \in \mathbb{N}_+$. Suppose also that N is a random variable taking values in \mathbb{N}_+ , independent of \mathbf{X} . Denote the probability density function of N by $p_n = \mathbb{P}(N = n)$ for $n \in \mathbb{N}_+$. The distribution of the random variable X_N is a mixture of the distributions of $\mathbf{X} = (X_1, X_2, \dots)$, with the distribution of N as the mixing distribution.

The conditional and ordinary expected value of X_N are

1. $\mathbb{E}(X_N \mid N) = \mu_N$
2. $\mathbb{E}(X_N) = \sum_{n=1}^{\infty} p_n \mu_n$

Proof

1. Using the substitution rule and the independence of N and \mathbf{X} , we have $\mathbb{E}(X_N \mid N = n) = \mathbb{E}(X_n \mid N = n) = \mathbb{E}(X_n) = \mu_n$
2. From (a) and the conditioning rule,

$$\mathbb{E}(X_N) = \mathbb{E}[\mathbb{E}(X_N)] = \mathbb{E}(\mu_N) = \sum_{n=1}^{\infty} p_n \mu_n \quad (4.7.48)$$

The conditional and ordinary variance of X_N are

1. $\text{var}(X_N \mid N) = \sigma_N^2$
2. $\text{var}(X_N) = \sum_{n=1}^{\infty} p_n (\sigma_n^2 + \mu_n^2) - (\sum_{n=1}^{\infty} p_n \mu_n)^2$.

Proof

1. Using the substitution rule and the independence of N and \mathbf{X} , we have $\text{var}(X_N \mid N = n) = \text{var}(X_n \mid N = n) = \text{var}(X_n) = \sigma_n^2$
2. From (a) we have

$$\text{var}(X_N) = \mathbb{E}[\text{var}(X_N \mid N)] + \text{var}[\mathbb{E}(X_N \mid N)] = \mathbb{E}(\sigma_N^2) + \text{var}(\mu_N) = \mathbb{E}(\sigma_N^2) + \mathbb{E}(\mu_N^2) - [\mathbb{E}(\mu_N)]^2 \quad (4.7.49)$$

$$= \sum_{n=1}^{\infty} p_n \sigma_n^2 + \sum_{n=1}^{\infty} p_n \mu_n^2 - \left(\sum_{n=1}^{\infty} p_n \mu_n \right)^2 \quad (4.7.50)$$

The conditional and ordinary moment generating function of X_N are

1. $\mathbb{E}(e^{tX_N} \mid N) = M_N(t)$
2. $\mathbb{E}(e^{tX_N}) = \sum_{i=1}^{\infty} p_i M_i(t)$.

Proof

1. Using the substitution rule and the independence of N and \mathbf{X} , we have $\mathbb{E}(e^{tX_N} \mid N = n) = \mathbb{E}(e^{tX_n} \mid N = n) = \mathbb{E}(e^{tX_n}) = M_n(t)$

2. From (a) and the conditioning rule, $\mathbb{E}(e^{tX_N}) = \mathbb{E}[\mathbb{E}(e^{tX_N} | N)] = \mathbb{E}[M_N(t)] = \sum_{n=1}^{\infty} p_n M_n(t)$

In the coin-die experiment, a biased coin is tossed with probability of heads $\frac{1}{3}$. If the coin lands tails, a fair die is rolled; if the coin lands heads, an ace-six flat die is rolled (faces 1 and 6 have probability $\frac{1}{4}$ each, and faces 2, 3, 4, 5 have probability $\frac{1}{8}$ each). Find the mean and standard deviation of the die score.

Answer

1. $\frac{7}{2}$
2. 1.8634

Run the coin-die experiment 1000 times and note the apparent convergence of the empirical mean and standard deviation to the distribution mean and standard deviation.

4.8: Expected Value and Covariance Matrices

The main purpose of this section is a discussion of expected value and covariance for random matrices and vectors. These topics are somewhat specialized, but are particularly important in multivariate statistical models and for the multivariate normal distribution. This section requires some prerequisite knowledge of linear algebra.

We assume that the various indices m, n, p, k that occur in this section are positive integers. Also we assume that expected values of real-valued random variables that we reference exist as real numbers, although extensions to cases where expected values are ∞ or $-\infty$ are straightforward, as long as we avoid the dreaded indeterminate form $\infty - \infty$.

Basic Theory

Linear Algebra

We will follow our usual convention of denoting random variables by upper case letters and nonrandom variables and constants by lower case letters. In this section, that convention leads to notation that is a bit nonstandard, since the objects that we will be dealing with are vectors and matrices. On the other hand, the notation we will use works well for illustrating the similarities between results for random matrices and the corresponding results in the one-dimensional case. Also, we will try to be careful to explicitly point out the underlying spaces where various objects live.

Let $\mathbb{R}^{m \times n}$ denote the space of all $m \times n$ matrices of real numbers. The (i, j) entry of $\mathbf{a} \in \mathbb{R}^{m \times n}$ is denoted a_{ij} for $i \in \{1, 2, \dots, m\}$ and $j \in \{1, 2, \dots, n\}$. We will identify \mathbb{R}^n with $\mathbb{R}^{n \times 1}$, so that an ordered n -tuple can also be thought of as an $n \times 1$ column vector. The transpose of a matrix $\mathbf{a} \in \mathbb{R}^{m \times n}$ is denoted \mathbf{a}^T —the $n \times m$ matrix whose (i, j) entry is the (j, i) entry of \mathbf{a} . Recall the definitions of matrix addition, scalar multiplication, and matrix multiplication. Recall also the standard inner product (or dot product) of $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$:

$$\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{x} \cdot \mathbf{y} = \mathbf{x}^T \mathbf{y} = \sum_{i=1}^n x_i y_i \quad (4.8.1)$$

The outer product of \mathbf{x} and \mathbf{y} is $\mathbf{x}\mathbf{y}^T$, the $n \times n$ matrix whose (i, j) entry is $x_i y_j$. Note that the inner product is the trace (sum of the diagonal entries) of the outer product. Finally recall the standard norm on \mathbb{R}^n , given by

$$\|\mathbf{x}\| = \sqrt{\langle \mathbf{x}, \mathbf{x} \rangle} = \sqrt{x_1^2 + x_2^2 + \dots + x_n^2} \quad (4.8.2)$$

Recall that inner product is *bilinear*, that is, linear (preserving addition and scalar multiplication) in each argument separately. As a consequence, for $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$,

$$\|\mathbf{x} + \mathbf{y}\|^2 = \|\mathbf{x}\|^2 + \|\mathbf{y}\|^2 + 2\langle \mathbf{x}, \mathbf{y} \rangle \quad (4.8.3)$$

Expected Value of a Random Matrix

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So to review, Ω is the set of outcomes, \mathcal{F} the collection of events, and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) . It's natural to define the expected value of a random matrix in a component-wise manner.

Suppose that \mathbf{X} is an $m \times n$ matrix of real-valued random variables, whose (i, j) entry is denoted X_{ij} . Equivalently, \mathbf{X} is as a random $m \times n$ matrix, that is, a random variable with values in $\mathbb{R}^{m \times n}$. The *expected value* $\mathbb{E}(\mathbf{X})$ is defined to be the $m \times n$ matrix whose (i, j) entry is $\mathbb{E}(X_{ij})$, the expected value of X_{ij} .

Many of the basic properties of expected value of random variables have analogous results for expected value of random matrices, with matrix operation replacing the ordinary ones. Our first two properties are the critically important *linearity properties*. The first part is the *additive property*—the expected value of a sum is the sum of the expected values.

$\mathbb{E}(\mathbf{X} + \mathbf{Y}) = \mathbb{E}(\mathbf{X}) + \mathbb{E}(\mathbf{Y})$ if \mathbf{X} and \mathbf{Y} are random $m \times n$ matrices.

Proof

This is true by definition of the matrix expected value and the ordinary additive property. Note that $\mathbb{E}(X_{ij} + Y_{ij}) = \mathbb{E}(X_{ij}) + \mathbb{E}(Y_{ij})$. The left side is the (i, j) entry of $\mathbb{E}(\mathbf{X} + \mathbf{Y})$ and the right side is the (i, j) entry of $\mathbb{E}(\mathbf{X}) + \mathbb{E}(\mathbf{Y})$.

The next part of the linearity properties is the *scaling property*—a nonrandom matrix factor can be pulled out of the expected value.

Suppose that \mathbf{X} is a random $n \times p$ matrix.

1. $\mathbb{E}(\mathbf{a}\mathbf{X}) = \mathbf{a}\mathbb{E}(\mathbf{X})$ if $\mathbf{a} \in \mathbb{R}^{m \times n}$.
2. $\mathbb{E}(\mathbf{X}\mathbf{a}) = \mathbb{E}(\mathbf{X})\mathbf{a}$ if $\mathbf{a} \in \mathbb{R}^{p \times n}$.

Proof

1. By the ordinary linearity and scaling properties, $\mathbb{E}\left(\sum_{j=1}^n a_{ij} X_{jk}\right) = \sum_{j=1}^n a_{ij} \mathbb{E}(X_{jk})$. The left side is the (i, k) entry of $\mathbb{E}(\mathbf{a}\mathbf{X})$ and the right side is the (i, k) entry of $\mathbf{a}\mathbb{E}(\mathbf{X})$.
2. The proof is similar to (a).

Recall that for independent, real-valued variables, the expected value of the product is the product of the expected values. Here is the analogous result for random matrices.

$\mathbb{E}(\mathbf{X}\mathbf{Y}) = \mathbb{E}(\mathbf{X})\mathbb{E}(\mathbf{Y})$ if \mathbf{X} is a random $m \times n$ matrix, \mathbf{Y} is a random $n \times p$ matrix, and \mathbf{X} and \mathbf{Y} are independent.

Proof

By the ordinary linearity properties and by the independence assumption,

$$\mathbb{E} \left(\sum_{j=1}^n X_{ij} Y_{jk} \right) = \sum_{j=1}^n \mathbb{E} (X_{ij} Y_{jk}) = \sum_{j=1}^n \mathbb{E} (X_{ij}) \mathbb{E} (Y_{jk}) \quad (4.8.4)$$

The left side is the (i, k) entry of $\mathbb{E}(\mathbf{XY})$ and the right side is the (i, k) entry of $\mathbb{E}(\mathbf{X})\mathbb{E}(\mathbf{Y})$.

Actually the previous result holds if \mathbf{X} and \mathbf{Y} are simply uncorrelated in the sense that X_{ij} and Y_{jk} are uncorrelated for each $i \in \{1, \dots, m\}$, $j \in \{1, 2, \dots, n\}$ and $k \in \{1, 2, \dots, p\}$. We will study covariance of random vectors in the next subsection.

Covariance Matrices

Our next goal is to define and study the covariance of two random vectors.

Suppose that \mathbf{X} is a random vector in \mathbb{R}^m and \mathbf{Y} is a random vector in \mathbb{R}^n .

1. The *covariance matrix* of \mathbf{X} and \mathbf{Y} is the $m \times n$ matrix $\text{cov}(\mathbf{X}, \mathbf{Y})$ whose (i, j) entry is $\text{cov}(X_i, Y_j)$ the ordinary covariance of X_i and Y_j .
2. Assuming that the coordinates of \mathbf{X} and \mathbf{Y} have positive variance, the *correlation matrix* of \mathbf{X} and \mathbf{Y} is the $m \times n$ matrix $\text{cor}(\mathbf{X}, \mathbf{Y})$ whose (i, j) entry is $\text{cor}(X_i, Y_j)$, the ordinary correlation of X_i and Y_j

Many of the standard properties of covariance and correlation for real-valued random variables have extensions to random vectors. For the following three results, \mathbf{X} is a random vector in \mathbb{R}^m and \mathbf{Y} is a random vector in \mathbb{R}^n .

$$\text{cov}(\mathbf{X}, \mathbf{Y}) = \mathbb{E} \left([\mathbf{X} - \mathbb{E}(\mathbf{X})] [\mathbf{Y} - \mathbb{E}(\mathbf{Y})]^T \right)$$

Proof

By the definition of the expected value of a random vector and by the definition of matrix multiplication, the (i, j) entry of $[\mathbf{X} - \mathbb{E}(\mathbf{X})] [\mathbf{Y} - \mathbb{E}(\mathbf{Y})]^T$ is simply $[X_i - \mathbb{E}(X_i)] [Y_j - \mathbb{E}(Y_j)]$. The expected value of this entry is $\text{cov}(X_i, Y_j)$, which in turn, is the (i, j) entry of $\text{cov}(\mathbf{X}, \mathbf{Y})$.

Thus, the covariance of \mathbf{X} and \mathbf{Y} is the expected value of the outer product of $\mathbf{X} - \mathbb{E}(\mathbf{X})$ and $\mathbf{Y} - \mathbb{E}(\mathbf{Y})$. Our next result is the computational formula for covariance: the expected value of the outer product of \mathbf{X} and \mathbf{Y} minus the outer product of the expected values.

$$\text{cov}(\mathbf{X}, \mathbf{Y}) = \mathbb{E}(\mathbf{XY}^T) - \mathbb{E}(\mathbf{X})[\mathbb{E}(\mathbf{Y})]^T.$$

Proof

The (i, j) entry of $\mathbb{E}(\mathbf{XY}^T) - \mathbb{E}(\mathbf{X})[\mathbb{E}(\mathbf{Y})]^T$ is $\mathbb{E}(X_i Y_j) - \mathbb{E}(X_i) \mathbb{E}(Y_j)$, which by the standard computational formula, is $\text{cov}(X_i, Y_j)$, which in turn is the (i, j) entry of $\text{cov}(\mathbf{X}, \mathbf{Y})$.

The next result is the matrix version of the symmetry property.

$$\text{cov}(\mathbf{Y}, \mathbf{X}) = [\text{cov}(\mathbf{X}, \mathbf{Y})]^T.$$

Proof

The (i, j) entry of $\text{cov}(\mathbf{X}, \mathbf{Y})$ is $\text{cov}(X_i, Y_j)$, which is the (j, i) entry of $\text{cov}(\mathbf{Y}, \mathbf{X})$.

In the following result, $\mathbf{0}$ denotes the $m \times n$ zero matrix.

$\text{cov}(\mathbf{X}, \mathbf{Y}) = \mathbf{0}$ if and only if $\text{cov}(X_i, Y_j) = 0$ for each i and j , so that each coordinate of \mathbf{X} is uncorrelated with each coordinate of \mathbf{Y} .

Proof

This follows immediately from the definition of $\text{cov}(\mathbf{X}, \mathbf{Y})$.

Naturally, when $\text{cov}(\mathbf{X}, \mathbf{Y}) = \mathbf{0}$, we say that the random vectors \mathbf{X} and \mathbf{Y} are *uncorrelated*. In particular, if the random vectors are independent, then they are uncorrelated. The following results establish the *bi-linear* properties of covariance.

The additive properties.

1. $\text{cov}(\mathbf{X} + \mathbf{Y}, \mathbf{Z}) = \text{cov}(\mathbf{X}, \mathbf{Z}) + \text{cov}(\mathbf{Y}, \mathbf{Z})$ if \mathbf{X} and \mathbf{Y} are random vectors in \mathbb{R}^m and \mathbf{Z} is a random vector in \mathbb{R}^n .
2. $\text{cov}(\mathbf{X}, \mathbf{Y} + \mathbf{Z}) = \text{cov}(\mathbf{X}, \mathbf{Y}) + \text{cov}(\mathbf{X}, \mathbf{Z})$ if \mathbf{X} is a random vector in \mathbb{R}^m , and \mathbf{Y} and \mathbf{Z} are random vectors in \mathbb{R}^n .

Proof

1. From the ordinary additive property of covariance, $\text{cov}(X_i + Y_i, Z_j) = \text{cov}(X_i, Z_j) + \text{cov}(Y_i, Z_j)$. The left side is the (i, j) entry of $\text{cov}(\mathbf{X} + \mathbf{Y}, \mathbf{Z})$ and the right side is the (i, j) entry of $\text{cov}(\mathbf{X}, \mathbf{Z}) + \text{cov}(\mathbf{Y}, \mathbf{Z})$.
2. The proof is similar to (a), using the additivity of covariance in the second argument.

The scaling properties

1. $\text{cov}(\mathbf{aX}, \mathbf{Y}) = \mathbf{a} \text{cov}(\mathbf{X}, \mathbf{Y})$ if \mathbf{X} is a random vector in \mathbb{R}^n , \mathbf{Y} is a random vector in \mathbb{R}^p , and $\mathbf{a} \in \mathbb{R}^{m \times n}$.
2. $\text{cov}(\mathbf{X}, \mathbf{aY}) = \text{cov}(\mathbf{X}, \mathbf{Y}) \mathbf{a}^T$ if \mathbf{X} is a random vector in \mathbb{R}^m , \mathbf{Y} is a random vector in \mathbb{R}^n , and $\mathbf{a} \in \mathbb{R}^{k \times n}$.

Proof

1. Using the ordinary linearity properties of covariance in the first argument, we have

$$\text{cov}\left(\sum_{j=1}^n a_{ij}X_j, Y_k\right) = \sum_{j=1}^n a_{ij}\text{cov}(X_j, Y_k) \quad (4.8.5)$$

The left side is the (i, k) entry of $\text{cov}(\mathbf{aX}, \mathbf{Y})$ and the right side is the (i, k) entry of $\mathbf{a}\text{cov}(\mathbf{X}, \mathbf{Y})$.
2. The proof is similar to (a), using the linearity of covariance in the second argument.

Variance-Covariance Matrices

Suppose that \mathbf{X} is a random vector in \mathbb{R}^n . The covariance matrix of \mathbf{X} with itself is called the *variance-covariance matrix* of \mathbf{X} :

$$\text{vc}(\mathbf{X}) = \text{cov}(\mathbf{X}, \mathbf{X}) = \mathbb{E}\left([\mathbf{X} - \mathbb{E}(\mathbf{X})][\mathbf{X} - \mathbb{E}(\mathbf{X})]^T\right) \quad (4.8.6)$$

Recall that for an ordinary real-valued random variable X , $\text{var}(X) = \text{cov}(X, X)$. Thus the variance-covariance matrix of a random vector in some sense plays the same role that variance does for a random variable.

$\text{vc}(\mathbf{X})$ is a symmetric $n \times n$ matrix with $(\text{var}(X_1), \text{var}(X_2), \dots, \text{var}(X_n))$ on the diagonal.

Proof

Recall that $\text{cov}(X_i, X_j) = \text{cov}(X_j, X_i)$. Also, the (i, i) entry of $\text{vc}(\mathbf{X})$ is $\text{cov}(X_i, X_i) = \text{var}(X_i)$.

The following result is the formula for the variance-covariance matrix of a sum, analogous to the formula for the variance of a sum of real-valued variables.

$\text{vc}(\mathbf{X} + \mathbf{Y}) = \text{vc}(\mathbf{X}) + \text{cov}(\mathbf{X}, \mathbf{Y}) + \text{cov}(\mathbf{Y}, \mathbf{X}) + \text{vc}(\mathbf{Y})$ if \mathbf{X} and \mathbf{Y} are random vectors in \mathbb{R}^n .

Proof

This follows from the additive property of covariance:

$$\text{vc}(\mathbf{X} + \mathbf{Y}) = \text{cov}(\mathbf{X} + \mathbf{Y}, \mathbf{X} + \mathbf{Y}) = \text{cov}(\mathbf{X}, \mathbf{X}) + \text{cov}(\mathbf{X}, \mathbf{Y}) + \text{cov}(\mathbf{Y}, \mathbf{X}) + \text{cov}(\mathbf{Y}, \mathbf{Y}) \quad (4.8.7)$$

Recall that $\text{var}(aX) = a^2\text{var}(X)$ if X is a real-valued random variable and $a \in \mathbb{R}$. Here is the analogous result for the variance-covariance matrix of a random vector.

$\text{vc}(\mathbf{aX}) = \mathbf{a}\text{vc}(\mathbf{X})\mathbf{a}^T$ if \mathbf{X} is a random vector in \mathbb{R}^n and $\mathbf{a} \in \mathbb{R}^{m \times n}$.

Proof

This follows from the scaling property of covariance:

$$\text{vc}(\mathbf{aX}) = \text{cov}(\mathbf{aX}, \mathbf{aX}) = \mathbf{a}\text{cov}(\mathbf{X}, \mathbf{X})\mathbf{a}^T \quad (4.8.8)$$

Recall that if X is a random variable, then $\text{var}(X) \geq 0$, and $\text{var}(X) = 0$ if and only if X is a constant (with probability 1). Here is the analogous result for a random vector:

Suppose that \mathbf{X} is a random vector in \mathbb{R}^n .

1. $\text{vc}(\mathbf{X})$ is either positive semi-definite or positive definite.
2. $\text{vc}(\mathbf{X})$ is positive semi-definite but not positive definite if and only if there exists $\mathbf{a} \in \mathbb{R}^n$ and $c \in \mathbb{R}$ such that, with probability 1, $\mathbf{a}^T \mathbf{X} = \sum_{i=1}^n a_i X_i = c$

Proof

1. From the previous result, $0 \leq \text{var}(\mathbf{a}^T \mathbf{X}) = \text{vc}(\mathbf{a}^T \mathbf{X}) = \mathbf{a}^T \text{vc}(\mathbf{X}) \mathbf{a}$ for every $\mathbf{a} \in \mathbb{R}^n$. Thus, by definition, $\text{vc}(\mathbf{X})$ is either positive semi-definite or positive definite.
2. In light of (a), $\text{vc}(\mathbf{X})$ is positive semi-definite but not positive definite if and only if there exists $\mathbf{a} \in \mathbb{R}^n$ such that $\mathbf{a}^T \text{vc}(\mathbf{X}) \mathbf{a} = \text{var}(\mathbf{a}^T \mathbf{X}) = 0$. But in turn, this is true if and only if $\mathbf{a}^T \mathbf{X}$ is constant with probability 1.

Recall that since $\text{vc}(\mathbf{X})$ is either positive semi-definite or positive definite, the eigenvalues and the determinant of $\text{vc}(\mathbf{X})$ are nonnegative. Moreover, if $\text{vc}(\mathbf{X})$ is positive semi-definite but not positive definite, then one of the coordinates of \mathbf{X} can be written as a linear transformation of the other coordinates (and hence can usually be eliminated in the underlying model). By contrast, if $\text{vc}(\mathbf{X})$ is positive definite, then this cannot happen; $\text{vc}(\mathbf{X})$ has positive eigenvalues and determinant and is invertible.

Best Linear Predictor

Suppose that \mathbf{X} is a random vector in \mathbb{R}^m and that \mathbf{Y} is a random vector in \mathbb{R}^n . We are interested in finding the function of \mathbf{X} of the form $\mathbf{a} + \mathbf{bX}$, where $\mathbf{a} \in \mathbb{R}^n$ and $\mathbf{b} \in \mathbb{R}^{n \times m}$, that is closest to \mathbf{Y} in the mean square sense. Functions of this form are analogous to linear functions in the single variable case. However, unless $\mathbf{a} = \mathbf{0}$, such functions are not *linear transformations* in the sense of linear algebra, so the correct term is *affine function* of \mathbf{X} . This problem is of fundamental importance in statistics when random vector \mathbf{X} , the *predictor vector* is observable, but not random vector \mathbf{Y} , the *response vector*. Our discussion here generalizes the one-dimensional case, when X and Y are random variables. That problem was solved in the section on Covariance and Correlation. We will assume that $\text{vc}(\mathbf{X})$ is positive definite, so that $\text{vc}(\mathbf{X})$ is invertible, and none of the coordinates of \mathbf{X} can be written as an affine function of the other coordinates. We write $\text{vc}^{-1}(\mathbf{X})$ for the inverse instead of the clunkier $[\text{vc}(\mathbf{X})]^{-1}$.

As with the single variable case, the solution turns out to be the affine function that has the same expected value as \mathbf{Y} , and whose covariance with \mathbf{X} is the same as that of \mathbf{Y} .

Define $L(\mathbf{Y} | \mathbf{X}) = \mathbb{E}(\mathbf{Y}) + \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})[\mathbf{X} - \mathbb{E}(\mathbf{X})]$. Then $L(\mathbf{Y} | \mathbf{X})$ is the only affine function of \mathbf{X} in \mathbb{R}^n satisfying

1. $\mathbb{E}[L(\mathbf{Y} | \mathbf{X})] = \mathbb{E}(\mathbf{Y})$
2. $\text{cov}[L(\mathbf{Y} | \mathbf{X}), \mathbf{X}] = \text{cov}(\mathbf{Y}, \mathbf{X})$

Proof

From linearity,

$$\mathbb{E}[L(\mathbf{Y} | \mathbf{X})] = E(\mathbf{Y}) + \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})[\mathbb{E}(\mathbf{X}) - \mathbb{E}(\mathbf{X})] = 0 \quad (4.8.9)$$

From linearity and the fact that a constant vector is independent (and hence uncorrelated) with any random vector,

$$\text{cov}[L(\mathbf{Y} | \mathbf{X}), \mathbf{X}] = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{cov}(\mathbf{X}, \mathbf{X}) = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{vc}(\mathbf{X}) = \text{cov}(\mathbf{Y}, \mathbf{X}) \quad (4.8.10)$$

Conversely, suppose that $\mathbf{U} = \mathbf{a} + \mathbf{b}\mathbf{X}$ for some $\mathbf{a} \in \mathbb{R}^n$ and $\mathbf{b} \in \mathbb{R}^{m \times n}$, and that $\mathbb{E}(\mathbf{U}) = \mathbb{E}(\mathbf{Y})$ and $\text{cov}(\mathbf{U}, \mathbf{X}) = \text{cov}(\mathbf{Y}, \mathbf{X})$. From the second equation, again using linearity and the uncorrelated property of constant vectors, we get $\mathbf{b}\text{cov}(\mathbf{X}, \mathbf{X}) = \text{cov}(\mathbf{Y}, \mathbf{X})$ and therefore $\mathbf{b} = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})$. Then from the first equation, $\mathbf{a} + \mathbf{b}\mathbb{E}(\mathbf{X}) = \mathbf{Y}$ so $\mathbf{a} = \mathbb{E}(\mathbf{Y}) - \mathbf{b}\mathbb{E}(\mathbf{X})$.

A simple corollary is the $\mathbf{Y} - L(\mathbf{Y} | \mathbf{X})$ is uncorrelated with any affine function of \mathbf{X} :

If \mathbf{U} is an affine function of \mathbf{X} then

1. $\text{cov}[\mathbf{Y} - L(\mathbf{Y} | \mathbf{X}), \mathbf{U}] = \mathbf{0}$
2. $\mathbb{E}(\langle \mathbf{Y} - L(\mathbf{Y} | \mathbf{X}), \mathbf{U} \rangle) = 0$

Proof

Suppose that $\mathbf{U} = \mathbf{a} + \mathbf{b}\mathbf{X}$ where $\mathbf{a} \in \mathbb{R}^n$ and $\mathbf{b} \in \mathbb{R}^{m \times n}$. For simplicity, let $\mathbf{L} = L(\mathbf{Y} | \mathbf{X})$

1. From the previous result, $\text{cov}(\mathbf{Y}, \mathbf{X}) = \text{cov}(\mathbf{L}, \mathbf{X})$. Hence using linearity,

$$\text{cov}(\mathbf{Y} - \mathbf{L}, \mathbf{U}) = \text{cov}(\mathbf{Y} - \mathbf{L}, \mathbf{a}) + \text{cov}(\mathbf{Y} - \mathbf{L}, \mathbf{X})\mathbf{b}^T = \mathbf{0} + [\text{cov}(\mathbf{Y}, \mathbf{X}) - \text{cov}(\mathbf{L}, \mathbf{X})] = \mathbf{0} \quad (4.8.11)$$

2. Recall that $\langle \mathbf{Y} - \mathbf{L}, \mathbf{U} \rangle$ is the trace of $\text{cov}(\mathbf{Y} - \mathbf{L}, \mathbf{U})$ and hence has expected value 0 by part (a).

The variance-covariance matrix of $L(\mathbf{Y} | \mathbf{X})$, and its covariance matrix with \mathbf{Y} turn out to be the same, again analogous to the single variable case.

Additional properties of $L(\mathbf{Y} | \mathbf{X})$:

1. $\text{cov}[\mathbf{Y}, L(\mathbf{Y} | \mathbf{X})] = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{cov}(\mathbf{X}, \mathbf{Y})$
2. $\text{vc}[L(\mathbf{Y} | \mathbf{X})] = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{cov}(\mathbf{X}, \mathbf{Y})$

Proof

Recall that $L(\mathbf{Y} | \mathbf{X}) = \mathbb{E}(\mathbf{Y}) + \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})[\mathbf{X} - \mathbb{E}(\mathbf{X})]$

1. Using basic properties of covariance,

$$\text{cov}[\mathbf{Y}, L(\mathbf{Y} | \mathbf{X})] = \text{cov}[\mathbf{Y}, \mathbf{X} - \mathbb{E}(\mathbf{X})] [\text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})]^T = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{cov}(\mathbf{X}, \mathbf{Y}) \quad (4.8.12)$$

2. Using basic properties of variance-covariance,

$$\text{vc}[L(\mathbf{Y} | \mathbf{X})] = \text{vc}[\text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\mathbf{X}] = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{vc}(\mathbf{X})[\text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})]^T = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{cov}(\mathbf{X}, \mathbf{Y}) \quad (4.8.13)$$

Next is the fundamental result that $L(\mathbf{Y} | \mathbf{X})$ is the affine function of \mathbf{X} that is closest to \mathbf{Y} in the mean square sense.

Suppose that $\mathbf{U} \in \mathbb{R}^n$ is an affine function of \mathbf{X} . Then

1. $\mathbb{E}(\|\mathbf{Y} - L(\mathbf{Y} | \mathbf{X})\|^2) \leq \mathbb{E}(\|\mathbf{Y} - \mathbf{U}\|^2)$
2. Equality holds in (a) if and only if $\mathbf{U} = L(\mathbf{Y} | \mathbf{X})$ with probability 1.

Proof

Again, let $\mathbf{L} = L(\mathbf{Y} | \mathbf{X})$ for simplicity and let $\mathbf{U} \in \mathbb{R}^n$ be an affine function of \mathbf{X} .

1. Using the linearity of expected value, note that

$$\mathbb{E}(\|\mathbf{Y} - \mathbf{U}\|^2) = \mathbb{E}(\|(\mathbf{Y} - \mathbf{L}) + (\mathbf{L} - \mathbf{U})\|^2) = \mathbb{E}(\|\mathbf{Y} - \mathbf{L}\|^2) + 2\mathbb{E}(\langle \mathbf{Y} - \mathbf{L}, \mathbf{L} - \mathbf{U} \rangle) + \mathbb{E}(\|\mathbf{L} - \mathbf{U}\|^2) \quad (4.8.14)$$

But $\mathbf{L} - \mathbf{U}$ is an affine function of \mathbf{X} and hence the middle term is 0 by our previous corollary. Hence

$$\mathbb{E}(\|\mathbf{Y} - \mathbf{U}\|^2) = \mathbb{E}(\|\mathbf{L} - \mathbf{Y}\|^2) + \mathbb{E}(\|\mathbf{L} - \mathbf{U}\|^2) \geq \mathbb{E}(\|\mathbf{L} - \mathbf{Y}\|^2)$$

2. From (a), equality holds in the inequality if and only if $\mathbb{E}(\|\mathbf{L} - \mathbf{U}\|^2) = 0$ if and only if $\mathbb{P}(\mathbf{L} = \mathbf{U}) = 1$.

The variance-covariance matrix of the difference between \mathbf{Y} and the best affine approximation is given in the next theorem.

$$\text{vc}[\mathbf{Y} - L(\mathbf{Y} | \mathbf{X})] = \text{vc}(\mathbf{Y}) - \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{cov}(\mathbf{X}, \mathbf{Y})$$

Proof

Again, we abbreviate $L(\mathbf{Y} | \mathbf{X})$ by \mathbf{L} . Using basic properties of variance-covariance matrices,

$$\text{vc}(\mathbf{Y} - \mathbf{L}) = \text{vc}(\mathbf{Y}) - \text{cov}(\mathbf{Y}, \mathbf{L}) - \text{cov}(\mathbf{L}, \mathbf{Y}) + \text{vc}(\mathbf{L}) \quad (4.8.15)$$

But $\text{cov}(\mathbf{Y}, \mathbf{L}) = \text{cov}(\mathbf{L}, \mathbf{Y}) = \text{vc}(\mathbf{L}) = \text{cov}(\mathbf{Y}, \mathbf{X})\text{vc}^{-1}(\mathbf{X})\text{cov}(\mathbf{Y}, \mathbf{X})$. Substituting gives the result.

The actual mean square error when we use $L(\mathbf{Y} | \mathbf{X})$ to approximate \mathbf{Y} , namely $\mathbb{E}(\|\mathbf{Y} - L(\mathbf{Y} | \mathbf{X})\|^2)$, is the trace (sum of the diagonal entries) of the variance-covariance matrix above. The function of \mathbf{x} given by

$$L(\mathbf{Y} | \mathbf{X} = \mathbf{x}) = \mathbb{E}(\mathbf{Y}) + \text{cov}(\mathbf{Y}, \mathbf{X}) \text{vc}^{-1}(\mathbf{X}) [\mathbf{x} - \mathbb{E}(\mathbf{X})] \quad (4.8.16)$$

is known as the (distribution) linear regression function. If we observe \mathbf{x} then $L(\mathbf{Y} | \mathbf{X} = \mathbf{x})$ is our best affine prediction of \mathbf{Y} .

Multiple linear regression is more powerful than it may at first appear, because it can be applied to non-linear transformations of the random vectors. That is, if $g: \mathbb{R}^m \rightarrow \mathbb{R}^j$ and $h: \mathbb{R}^n \rightarrow \mathbb{R}^k$ then $L[h(\mathbf{Y}) | g(\mathbf{X})]$ is the affine function of $g(\mathbf{X})$ that is closest to $h(\mathbf{Y})$ in the mean square sense. Of course, we must be able to compute the appropriate means, variances, and covariances.

Moreover, *Non-linear regression* with a single, real-valued predictor variable can be thought of as a special case of multiple linear regression. Thus, suppose that X is the predictor variable, Y is the response variable, and that (g_1, g_2, \dots, g_n) is a sequence of real-valued functions. We can apply the results of this section to find the linear function of $(g_1(X), g_2(X), \dots, g_n(X))$ that is closest to Y in the mean square sense. We just replace X_i with $g_i(X)$ for each i . Again, we must be able to compute the appropriate means, variances, and covariances to do this.

Examples and Applications

Suppose that (X, Y) has probability density function f defined by $f(x, y) = x + y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$. Find each of the following:

1. $\mathbb{E}(X, Y)$
2. $\text{vc}(X, Y)$

Answer

1. $\left(\frac{7}{12}, \frac{7}{12}\right)$
2. $\begin{bmatrix} \frac{11}{144} & -\frac{1}{144} \\ -\frac{1}{144} & \frac{11}{144} \end{bmatrix}$

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 2(x + y)$ for $0 \leq x \leq y \leq 1$. Find each of the following:

1. $\mathbb{E}(X, Y)$
2. $\text{vc}(X, Y)$

Answer

1. $\left(\frac{5}{12}, \frac{3}{4}\right)$
2. $\begin{bmatrix} \frac{43}{720} & \frac{1}{48} \\ \frac{1}{48} & \frac{3}{80} \end{bmatrix}$

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 6x^2y$ for $0 \leq x \leq 1, 0 \leq y \leq 1$. Find each of the following:

1. $\mathbb{E}(X, Y)$
2. $\text{vc}(X, Y)$

Answer

Note that X and Y are independent.

1. $\left(\frac{3}{4}, \frac{2}{3}\right)$
2. $\begin{bmatrix} \frac{3}{80} & 0 \\ 0 & \frac{1}{18} \end{bmatrix}$

Suppose that (X, Y) has probability density function f defined by $f(x, y) = 15x^2y$ for $0 \leq x \leq y \leq 1$. Find each of the following:

1. $\mathbb{E}(X, Y)$
2. $\text{vc}(X, Y)$
3. $L(Y | X)$
4. $L[Y | (X, X^2)]$
5. Sketch the regression curves on the same set of axes.

Answer

1. $\left(\frac{5}{8}, \frac{5}{6}\right)$
2. $\begin{bmatrix} \frac{17}{448} & \frac{5}{336} \\ \frac{5}{336} & \frac{5}{252} \end{bmatrix}$
3. $\frac{10}{17} + \frac{20}{51}X$
4. $\frac{49}{76} + \frac{10}{57}X + \frac{7}{38}X^2$

Suppose that (X, Y, Z) is uniformly distributed on the region $\{(x, y, z) \in \mathbb{R}^3 : 0 \leq x \leq y \leq z \leq 1\}$. Find each of the following:

1. $\mathbb{E}(X, Y, Z)$
2. $\text{vc}(X, Y, Z)$

3. $L[Z | (X, Y)]$
4. $L[Y | (X, Z)]$
5. $L[X | (Y, Z)]$
6. $L[(Y, Z) | X]$

Answer

1. $(\frac{1}{4}, \frac{1}{2}, \frac{3}{4})$
2. $\begin{bmatrix} \frac{3}{80} & \frac{1}{40} & \frac{1}{80} \\ \frac{1}{40} & \frac{1}{20} & \frac{1}{40} \\ \frac{1}{80} & \frac{1}{40} & \frac{3}{80} \end{bmatrix}$
3. $\frac{1}{2} + \frac{1}{2}Y$. Note that there is no X term.
4. $\frac{1}{2}X + \frac{1}{2}Z$. Note that this is the midpoint of the interval $[X, Z]$.
5. $\frac{1}{2}Y$. Note that there is no Z term.
6. $\begin{bmatrix} \frac{1}{3} + \frac{2}{3}X \\ \frac{2}{3} + \frac{1}{3}X \end{bmatrix}$

Suppose that X is uniformly distributed on $(0, 1)$, and that given X , random variable Y is uniformly distributed on $(0, X)$. Find each of the following:

1. $\mathbb{E}(X, Y)$
2. $\text{vc}(X, Y)$

Answer

1. $(\frac{1}{2}, \frac{1}{4})$
2. $\begin{bmatrix} \frac{1}{12} & \frac{1}{24} \\ \frac{1}{24} & \frac{7}{144} \end{bmatrix}$

4.9: Expected Value as an Integral

In the introductory section, we defined expected value separately for discrete, continuous, and mixed distributions, using density functions. In the section on additional properties, we showed how these definitions can be unified, by first defining expected value for nonnegative random variables in terms of the right-tail distribution function. However, by far the best and most elegant definition of expected value is as an integral with respect to the underlying probability measure. This definition and a review of the properties of expected value are the goals of this section. No proofs are necessary (you will be happy to know), since all of the results follow from the general theory of integration. However, to understand the exposition, you will need to review the advanced sections on the integral with respect to a positive measure and the properties of the integral. If you are a new student of probability, or are not interested in the measure-theoretic detail of the subject, you can safely skip this section.

Definitions

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So Ω is the set of outcomes, \mathcal{F} is the σ -algebra of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) .

Recall that a random variable X for the experiment is simply a measurable function from (Ω, \mathcal{F}) into another measurable space (S, \mathcal{S}) . When $S \subseteq \mathbb{R}^n$, we assume that S is Lebesgue measurable, and we take \mathcal{S} to be the σ -algebra of Lebesgue measurable subsets of S . As noted above, here is the measure-theoretic definition:

If X is a real-valued random variable on the probability space, the expected value of X is defined as the integral of X with respect to \mathbb{P} , assuming that the integral exists:

$$\mathbb{E}(X) = \int_{\Omega} X d\mathbb{P} \quad (4.9.1)$$

Let's review how the integral is defined in stages, but now using the notation of probability theory.

Let S denote the support set of X , so that S is a measurable subset of \mathbb{R} .

1. If S is finite, then $\mathbb{E}(X) = \sum_{x \in S} x \mathbb{P}(X = x)$.
2. If $S \subseteq [0, \infty)$, then $\mathbb{E}(X) = \sup \{ \mathbb{E}(Y) : Y \text{ has finite range and } 0 \leq Y \leq X \}$
3. For general $S \subseteq \mathbb{R}$, $\mathbb{E}(X) = \mathbb{E}(X^+) - \mathbb{E}(X^-)$ as long as the right side is not of the form $\infty - \infty$, and where X^+ and X^- denote the positive and negative parts of X .
4. If $A \in \mathcal{F}$, then $\mathbb{E}(X; A) = \mathbb{E}(X \mathbf{1}_A)$, assuming that the expected value on the right exists.

Thus, as with integrals generally, an expected value can exist as a number in \mathbb{R} (in which case X is *integrable*), can exist as ∞ or $-\infty$, or can fail to exist. In reference to part (a), a random variable with a finite set of values in \mathbb{R} is a *simple function* in the terminology of general integration. In reference to part (b), note that the expected value of a nonnegative random variable always exists in $[0, \infty]$. In reference to part (c), $\mathbb{E}(X)$ exists if and only if either $\mathbb{E}(X^+) < \infty$ or $\mathbb{E}(X^-) < \infty$.

Our next goal is to restate the basic theorems and properties of integrals, but in the notation of probability. Unless otherwise noted, all random variables are assumed to be real-valued.

Basic Properties

The Linear Properties

Perhaps the most important and basic properties are the *linear properties*. Part (a) is the *additive property* and part (b) is the *scaling property*.

Suppose that X and Y are random variables whose expected values exist, and that $c \in \mathbb{R}$. Then

1. $\mathbb{E}(X + Y) = \mathbb{E}(X) + \mathbb{E}(Y)$ as long as the right side is not of the form $\infty - \infty$.
2. $\mathbb{E}(cX) = c\mathbb{E}(X)$

Thus, part (a) holds if at least one of the expected values on the right is finite, or if both are ∞ , or if both are $-\infty$. What is ruled out are the two cases where one expected value is ∞ and the other is $-\infty$, and this is what is meant by the indeterminate form $\infty - \infty$.

Equality and Order

Our next set of properties deal with equality and order. First, the expected value of a random variable over a null set is 0.

If X is a random variable and A is an event with $\mathbb{P}(A) = 0$. Then $\mathbb{E}(X; A) = 0$.

Random variables that are equivalent have the same expected value

If X is a random variable whose expected value exists, and Y is a random variable with $\mathbb{P}(X = Y) = 1$, then $\mathbb{E}(X) = \mathbb{E}(Y)$.

Our next result is the *positive property* of expected value.

Suppose that X is a random variable and $\mathbb{P}(X \geq 0) = 1$. Then

1. $\mathbb{E}(X) \geq 0$
2. $\mathbb{E}(X) = 0$ if and only if $\mathbb{P}(X = 0) = 1$.

So, if X is a nonnegative random variable then $\mathbb{E}(X) > 0$ if and only if $\mathbb{P}(X > 0) > 0$. The next result is the *increasing property* of expected value, perhaps the most important property after linearity.

Suppose that X, Y are random variables whose expected values exist, and that $\mathbb{P}(X \leq Y) = 1$. Then

1. $\mathbb{E}(X) \leq \mathbb{E}(Y)$
2. Except in the case that both expected values are ∞ or both $-\infty$, $\mathbb{E}(X) = \mathbb{E}(Y)$ if and only if $\mathbb{P}(X = Y) = 1$.

So if $X \leq Y$ with probability 1 then, except in the two cases mentioned, $\mathbb{E}(X) < \mathbb{E}(Y)$ if and only if $\mathbb{P}(X < Y) > 0$. The next result is the *absolute value inequality*.

Suppose that X is a random variable whose expected value exists. Then

1. $|\mathbb{E}(X)| \leq \mathbb{E}(|X|)$
2. If $\mathbb{E}(X)$ is finite, then equality holds in (a) if and only if $\mathbb{P}(X \geq 0) = 1$ or $\mathbb{P}(X \leq 0) = 1$.

Change of Variables and Density Functions

The Change of Variables Theorem

Suppose now that X is a general random variable on the probability space $(\Omega, \mathcal{F}, \mathbb{P})$, taking values in a measurable space (S, \mathcal{S}) . Recall that the *probability distribution* of X is the probability measure P on (S, \mathcal{S}) given by $P(A) = \mathbb{P}(X \in A)$ for $A \in \mathcal{S}$. This is a special case of a new positive measure induced by a given positive measure and a measurable function. If $g: S \rightarrow \mathbb{R}$ is measurable, then $g(X)$ is a real-valued random variable. The following result shows how to compute the expected value of $g(X)$ as an integral with respect to the distribution of X , and is known as the *change of variables theorem*.

If $g: S \rightarrow \mathbb{R}$ is measurable then, assuming that the expected value exists,

$$\mathbb{E}[g(X)] = \int_S g(x) dP(x) \quad (4.9.2)$$

So, using the original definition and the change of variables theorem, and giving the variables explicitly for emphasis, we have

$$\mathbb{E}[g(X)] = \int_{\Omega} g[X(\omega)] d\mathbb{P}(\omega) = \int_S g(x) dP(x) \quad (4.9.3)$$

The Radon-Nikodym Theorem

Suppose now μ is a positive measure on (S, \mathcal{S}) , and that the distribution of X is absolutely continuous with respect to μ . Recall that this means that $\mu(A) = 0$ implies $P(A) = \mathbb{P}(X \in A) = 0$ for $A \in \mathcal{S}$. By the *Radon-Nikodym theorem*, named for Johann Radon and Otto Nikodym, X has a *probability density function* f with respect to μ . That is,

$$P(A) = \mathbb{P}(X \in A) = \int_A f d\mu, \quad A \in \mathcal{S} \quad (4.9.4)$$

In this case, we can write the expected value of $g(X)$ as an integral with respect to the probability density function.

If $g: S \rightarrow \mathbb{R}$ is measurable then, assuming that the expected value exists,

$$\mathbb{E}[g(X)] = \int_S g f d\mu \quad (4.9.5)$$

Again, giving the variables explicitly for emphasis, we have the following chain of integrals:

$$\mathbb{E}[g(X)] = \int_{\Omega} g[X(\omega)] d\mathbb{P}(\omega) = \int_S g(x) dP(x) = \int_S g(x) f(x) d\mu(x) \quad (4.9.6)$$

There are two critically important special cases.

Discrete Distributions

Suppose first that $(S, \mathcal{S}, \#)$ is a *discrete measure space*, so that S is countable, $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S , and $\#$ is counting measure on (S, \mathcal{S}) . Thus, X has a discrete distribution on S , and this distribution is always absolutely continuous with respect to $\#$. Specifically, $\#(A) = 0$ if and only if $A = \emptyset$ and of course $\mathbb{P}(X \in \emptyset) = 0$. The probability density function f of X with respect to $\#$, as we know, is simply $f(x) = \mathbb{P}(X = x)$ for $x \in S$. Moreover, integrals with respect to $\#$ are sums, so

$$\mathbb{E}[g(X)] = \sum_{x \in S} g(x) f(x) \quad (4.9.7)$$

assuming that the expected value exists. Existence in this case means that either the sum of the positive terms is finite or the sum of the negative terms is finite, so that the sum makes sense (and in particular does not depend on the order in which the terms are added). Specializing further, if X itself is real-valued and $g = 1$ we have

$$\mathbb{E}(X) = \sum_{x \in S} x f(x) \quad (4.9.8)$$

which was our original definition of expected value in the discrete case.

Continuous Distributions

For the second special case, suppose that $(S, \mathcal{S}, \lambda_n)$ is a *Euclidean measure space*, so that S is a Lebesgue measurable subset of \mathbb{R}^n for some $n \in \mathbb{N}_+$, \mathcal{S} is the σ -algebra of Lebesgue measurable subsets of S , and λ_n is Lebesgue measure on (S, \mathcal{S}) . The distribution of X is absolutely continuous with respect to λ_n if $\lambda_n(A) = 0$ implies $\mathbb{P}(X \in A) = 0$ for $A \in \mathcal{S}$. If this is the case, then a probability density function f of X has its usual meaning. Thus,

$$\mathbb{E}[g(X)] = \int_S g(x)f(x) d\lambda_n(x) \quad (4.9.9)$$

assuming that the expected value exists. When g is a typically nice function, this integral reduces to an ordinary n -dimensional Riemann integral of calculus. Specializing further, if X is itself real-valued and $g = 1$ then

$$\mathbb{E}(X) = \int_S x f(x) dx \quad (4.9.10)$$

which was our original definition of expected value in the continuous case.

Interchange Properties

In this subsection, we review properties that allow the interchange of expected value and other operations: limits of sequences, infinite sums, and integrals. We assume again that the random variables are real-valued unless otherwise specified.

Limits

Our first set of convergence results deals with the interchange of expected value and limits. We start with the expected value version of *Fatou's lemma*, named in honor of Pierre Fatou. Its usefulness stems from the fact that no assumptions are placed on the random variables, except that they be nonnegative.

Suppose that X_n is a nonnegative random variable for $n \in \mathbb{N}_+$. Then

$$\mathbb{E}\left(\liminf_{n \rightarrow \infty} X_n\right) \leq \liminf_{n \rightarrow \infty} \mathbb{E}(X_n) \quad (4.9.11)$$

Our next set of results gives conditions for the interchange of expected value and limits.

Suppose that X_n is a random variable for each $n \in \mathbb{N}_+$. then

$$\mathbb{E}\left(\lim_{n \rightarrow \infty} X_n\right) = \lim_{n \rightarrow \infty} \mathbb{E}(X_n) \quad (4.9.12)$$

in each of the following cases:

1. X_n is nonnegative for each $n \in \mathbb{N}_+$ and X_n is increasing in n .
2. $\mathbb{E}(X_n)$ exists for each $n \in \mathbb{N}_+$, $\mathbb{E}(X_1) > -\infty$, and X_n is increasing in n .
3. $\mathbb{E}(X_n)$ exists for each $n \in \mathbb{N}_+$, $\mathbb{E}(X_1) < \infty$, and X_n is decreasing in n .
4. $\lim_{n \rightarrow \infty} X_n$ exists, and $|X_n| \leq Y$ for $n \in \mathbb{N}$ where Y is a nonnegative random variable with $\mathbb{E}(Y) < \infty$.
5. $\lim_{n \rightarrow \infty} X_n$ exists, and $|X_n| \leq c$ for $n \in \mathbb{N}$ where c is a positive constant.

Statements about the random variables in the theorem above (nonnegative, increasing, existence of limit, etc.) need only hold with probability 1. Part (a) is the *monotone convergence theorem*, one of the most important convergence results and in a sense, essential to the definition of the integral in the first place. Parts (b) and (c) are slight generalizations of the monotone convergence theorem. In parts (a), (b), and (c), note that $\lim_{n \rightarrow \infty} X_n$ exists (with probability 1), although the limit may be ∞ in parts (a) and (b) and $-\infty$ in part (c) (with positive probability). Part (d) is the *dominated convergence theorem*, another of the most important convergence results. It's sometimes also known as *Lebesgue's dominated convergence theorem* in honor of Henri Lebesgue. Part (e) is a corollary of the dominated convergence theorem, and is known as the *bounded convergence theorem*.

Infinite Series

Our next results involve the interchange of expected value and an infinite sum, so these results generalize the basic additivity property of expected value.

Suppose that X_n is a random variable for $n \in \mathbb{N}_+$. Then

$$\mathbb{E}\left(\sum_{n=1}^{\infty} X_n\right) = \sum_{n=1}^{\infty} \mathbb{E}(X_n) \quad (4.9.13)$$

in each of the following cases:

1. X_n is nonnegative for each $n \in \mathbb{N}_+$.
2. $\mathbb{E}(\sum_{n=1}^{\infty} |X_n|) < \infty$

Part (a) is a consequence of the monotone convergence theorem, and part (b) is a consequence of the dominated convergence theorem. In (b), note that $\sum_{n=1}^{\infty} |X_n| < \infty$ and hence $\sum_{n=1}^{\infty} X_n$ is absolutely convergent with probability 1. Our next result is the additivity of the expected value over a countably infinite collection of disjoint events.

Suppose that X is a random variable whose expected value exists, and that $\{A_n : n \in \mathbb{N}_+\}$ is a disjoint collection events. Let $A = \bigcup_{n=1}^{\infty} A_n$. Then

$$\mathbb{E}(X; A) = \sum_{n=1}^{\infty} \mathbb{E}(X; A_n) \quad (4.9.14)$$

Of course, the previous theorem applies in particular if X is nonnegative.

Integrals

Suppose that (T, \mathcal{T}, μ) is a σ -finite measure space, and that X_t is a real-valued random variable for each $t \in T$. Thus we can think of $\{X_t : t \in T\}$ is a stochastic process indexed by T . We assume that $(\omega, t) \mapsto X_t(\omega)$ is measurable, as a function from the product space $(\Omega \times T, \mathcal{F} \otimes \mathcal{T})$ into \mathbb{R} . Our next result involves the interchange of expected value and integral, and is a consequence of Fubini's theorem, named for Guido Fubini.

Under the assumptions above,

$$\mathbb{E} \left[\int_T X_t d\mu(t) \right] = \int_T \mathbb{E}(X_t) d\mu(t) \quad (4.9.15)$$

in each of the following cases:

1. X_t is nonnegative for each $t \in T$.
2. $\int_T \mathbb{E}(|X_t|) d\mu(t) < \infty$

Fubini's theorem actually states that the two iterated integrals above equal the joint integral

$$\int_{\Omega \times T} X_t(\omega) d(\mathbb{P} \otimes \mu)(\omega, t) \quad (4.9.16)$$

where of course, $\mathbb{P} \otimes \mu$ is the product measure on $(\Omega \times T, \mathcal{F} \otimes \mathcal{T})$. However, our interest is usually in evaluating the iterated integral above on the left in terms of the iterated integral on the right. Part (a) is the expected value version of *Tonelli's theorem*, named for Leonida Tonelli.

Examples and Exercises

You may have worked some of the computational exercises before, but try to see them in a new light, in terms of the general theory of integration.

The Cauchy Distribution

Recall that the *Cauchy distribution*, named for Augustin Cauchy, is a continuous distribution with probability density function f given by

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad x \in \mathbb{R} \quad (4.9.17)$$

The Cauchy distribution is studied in more generality in the chapter on Special Distributions.

Suppose that X has the Cauchy distribution.

1. Show that $\mathbb{E}(X)$ does not exist.
2. Find $\mathbb{E}(X^2)$

Answer

1. $\mathbb{E}(X^+) = \mathbb{E}(X^-) = \infty$
2. ∞

Open the Cauchy Experiment and keep the default parameters. Run the experiment 1000 times and note the behavior of the sample mean.

The Pareto Distribution

Recall that the *Pareto distribution*, named for Vilfredo Pareto, is a continuous distribution with probability density function f given by

$$f(x) = \frac{a}{x^{a+1}}, \quad x \in [1, \infty) \quad (4.9.18)$$

where $a > 0$ is the *shape parameter*. The Pareto distribution is studied in more generality in the chapter on Special Distributions.

Suppose that X has the Pareto distribution with shape parameter a . Find $\mathbb{E}(X)$ in the following cases:

1. $0 < a \leq 1$
2. $a > 1$

Answer

1. ∞
2. $\frac{a}{a-1}$

Open the special distribution simulator and select the Pareto distribution. Vary the shape parameter and note the shape of the probability density function and the location of the mean. For various values of the parameter, run the experiment 1000 times and compare the sample mean with the distribution mean.

Suppose that X has the Pareto distribution with shape parameter a . Find $E(1/X^n)$ for $n \in \mathbb{N}_+$.

Answer

$$\frac{a}{a+n}$$

Special Results for Nonnegative Variables

For a nonnegative variable, the moments can be obtained from integrals of the right-tail distribution function.

If X is a nonnegative random variable then

$$\mathbb{E}(X^n) = \int_0^\infty nx^{n-1}\mathbb{P}(X > x) dx \quad (4.9.19)$$

Proof

By [Fubini's theorem](#) we can interchange an expected value and integral when the integrand is nonnegative. Hence

$$\int_0^\infty nx^{n-1}\mathbb{P}(X > x) dx = \int_0^\infty nx^{n-1}\mathbb{E}[\mathbf{1}(X > x)] dx = \mathbb{E}\left(\int_0^\infty nx^{n-1}\mathbf{1}(X > x) dx\right) = \mathbb{E}\left(\int_0^X nx^{n-1} dx\right) = \mathbb{E}(X^n) \quad (4.9.20)$$

When $n = 1$ we have $\mathbb{E}(X) = \int_0^\infty \mathbb{P}(X > x) dx$. We saw this result before in the section on additional properties of expected value, but now we can understand the proof in terms of Fubini's theorem.

For a random variable taking nonnegative integer values, the moments can be computed from sums involving the right-tail distribution function.

Suppose that X has a discrete distribution, taking values in \mathbb{N} . Then

$$\mathbb{E}(X^n) = \sum_{k=1}^\infty [k^n - (k-1)^n] \mathbb{P}(X \geq k) \quad (4.9.21)$$

Proof

By the [theorem above](#), we can interchange expected value and infinite series when the terms are nonnegative. Hence

$$\begin{aligned} \sum_{k=1}^\infty [k^n - (k-1)^n] \mathbb{P}(X \geq k) &= \sum_{k=1}^\infty [k^n - (k-1)^n] \mathbb{E}[\mathbf{1}(X \geq k)] = \mathbb{E}\left(\sum_{k=1}^\infty [k^n - (k-1)^n] \mathbf{1}(X \geq k)\right) \\ &= \mathbb{E}\left(\sum_{k=1}^X [k^n - (k-1)^n]\right) = \mathbb{E}(X^n) \end{aligned} \quad (4.9.22)$$

When $n = 1$ we have $\mathbb{E}(X) = \sum_{k=1}^\infty \mathbb{P}(X \geq k)$. We saw this result before in the section on additional properties of expected value, but now we can understand the proof in terms of the interchange of sum and expected value.

4.10: Conditional Expected Value Revisited

Conditional expected value is much more important than one might at first think. In fact, conditional expected value is at the core of modern probability theory because it provides the basic way of incorporating known information into a probability measure.

Basic Theory

Definition

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$, so that Ω is the set of outcomes, \mathcal{F} is the σ -algebra of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . In our first elementary discussion, we studied the conditional expected value of a real-value random variable X given a general random variable Y . The more general approach is to condition on a sub σ -algebra \mathcal{G} of \mathcal{F} . The sections on σ -algebras and measure theory are essential prerequisites for this section.

Before we get to the definition, we need some preliminaries. First, all random variables mentioned are assumed to be real valued. Next the notion of equivalence plays a fundamental role in this section. Next recall that random variables X_1 and X_2 are *equivalent* if $\mathbb{P}(X_1 = X_2) = 1$. Equivalence really does define an equivalence relation on the collection of random variables defined on the sample space. Moreover, we often regard equivalent random variables as being essentially the same object. More precisely from this point of view, the objects of our study are not individual random variables but rather equivalence classes of random variables under this equivalence relation. Finally, for $A \in \mathcal{F}$, recall the notation for the expected value of X on the event A

$$\mathbb{E}(X; A) = \mathbb{E}(X \mathbf{1}_A) \quad (4.10.1)$$

assuming of course that the expected value exists. For the remainder of this subsection, suppose that \mathcal{G} is a sub σ -algebra of \mathcal{F} .

Suppose that X is a random variable with $\mathbb{E}(|X|) < \infty$. The *conditional expected value* of X given \mathcal{G} is the random variable $\mathbb{E}(X | \mathcal{G})$ defined by the following properties:

1. $\mathbb{E}(X | \mathcal{G})$ is measurable with respect to \mathcal{G} .
2. If $A \in \mathcal{G}$ then $\mathbb{E}[\mathbb{E}(X | \mathcal{G}); A] = \mathbb{E}(X; A)$

The basic idea is that $\mathbb{E}(X | \mathcal{G})$ is the expected value of X given the information in the σ -algebra \mathcal{G} . Hopefully this idea will become clearer during our study. The conditions above uniquely define $\mathbb{E}(X | \mathcal{G})$ up to equivalence. The proof of this fact is a simple application of the Radon-Nikodym theorem, named for Johann Radon and Otto Nikodym

Suppose again that X is a random variable with $\mathbb{E}(|X|) < \infty$.

1. There exists a random variable V satisfying the [definition](#).
2. If V_1 and V_2 satisfy the [definition](#), then $\mathbb{P}(V_1 = V_2) = 1$ so that V_1 and V_2 are equivalent.

Proof

1. Note that $\nu(A) = \mathbb{E}(X; A)$ for $A \in \mathcal{G}$ defines a (signed) measure on \mathcal{G} . Moreover, if $A \in \mathcal{G}$ and $\mathbb{P}(A) = 0$ then $\nu(A) = 0$. Hence ν is absolutely continuous with respect to the restriction of \mathbb{P} to \mathcal{G} . By the Radon-Nikodym theorem, there exists a random variable V that is measurable with respect to \mathcal{G} such that $\nu(A) = \mathbb{E}(V; A)$ for $A \in \mathcal{G}$. That is, V is the *density* or *derivative* of ν with respect to \mathbb{P} on \mathcal{G} .
2. This follows from the uniqueness of the Radon-Nikodym derivative, up to equivalence.

The following characterization might seem stronger but in fact is equivalent to the definition.

Suppose again that X is a random variable with $\mathbb{E}(|X|) < \infty$. Then $\mathbb{E}(X | \mathcal{G})$ is characterized by the following properties:

1. $\mathbb{E}(X | \mathcal{G})$ is measurable with respect to \mathcal{G}
2. If U is measurable with respect to \mathcal{G} and $\mathbb{E}(|UX|) < \infty$ then $\mathbb{E}[U\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(UX)$.

Proof

We have to show that part (b) in the [definition](#) is equivalent to part (b) here. First (b) here implies (b) in the definition since $\mathbf{1}_A$ is \mathcal{G} -measurable if $A \in \mathcal{G}$. Conversely suppose that (b) in the definition holds. We will show that (b) here holds by a classical *bootstrapping argument*. First $\mathbb{E}[U\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(UX)$ if $U = \mathbf{1}_A$ for some $A \in \mathcal{G}$. Next suppose that U is a simple random variable that is \mathcal{G} -measurable. That is, $U = \sum_{i \in I} a_i \mathbf{1}_{A_i}$ where I is a finite index set, $a_i \geq 0$ for $i \in I$, and $A_i \in \mathcal{G}$ for $i \in I$. then

$$\mathbb{E}[U\mathbb{E}(X | \mathcal{G})] = \mathbb{E}\left[\sum_{i \in I} a_i \mathbf{1}_{A_i} \mathbb{E}(X | \mathcal{G})\right] = \sum_{i \in I} a_i \mathbb{E}[\mathbf{1}_{A_i} \mathbb{E}(X | \mathcal{G})] = \sum_{i \in I} a_i \mathbb{E}(\mathbf{1}_{A_i} X) = \mathbb{E}\left(\sum_{i \in I} a_i \mathbf{1}_{A_i} X\right) = \mathbb{E}(UX) \quad (4.10.2)$$

Next suppose that U is nonnegative and \mathcal{G} -measurable. Then there exists a sequence of simple \mathcal{G} -measurable random variables (U_1, U_2, \dots) with $U_n \uparrow U$ as $n \rightarrow \infty$. Then by the previous step, $\mathbb{E}[U_n \mathbb{E}(X | \mathcal{G})] = \mathbb{E}(U_n X)$ for each n . Letting $n \rightarrow \infty$ and using the monotone convergence theorem we have $\mathbb{E}[U\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(UX)$. Finally, suppose that U is a general \mathcal{G} -measurable random variable. Then $U = U^+ - U^-$ where U^+ and U^- are the usual positive and negative parts of U . These parts are nonnegative and \mathcal{G} -measurable, so by the previous step, $\mathbb{E}[U^+ \mathbb{E}(X | \mathcal{G})] = \mathbb{E}(U^+ X)$ and $\mathbb{E}[U^- \mathbb{E}(X | \mathcal{G})] = \mathbb{E}(U^- X)$. hence

$$\mathbb{E}[U\mathbb{E}(X | \mathcal{G})] = \mathbb{E}[(U^+ - U^-)\mathbb{E}(X | \mathcal{G})] = \mathbb{E}[U^+ \mathbb{E}(X | \mathcal{G})] - \mathbb{E}[U^- \mathbb{E}(X | \mathcal{G})] = \mathbb{E}(U^+ X) - \mathbb{E}(U^- X) = \mathbb{E}(UX) \quad (4.10.3)$$

Properties

Our next discussion concerns some fundamental properties of conditional expected value. All equalities and inequalities are understood to hold *modulo equivalence*, that is, with probability 1. Note also that many of the proofs work by showing that the right hand side satisfies the properties in the [definition](#) for the conditional expected value on the left side. Once again we assume that \mathcal{G} is a sub *sigma*-algebra of \mathcal{F} .

Our first property is a simple consequence of the definition: X and $\mathbb{E}(X | \mathcal{G})$ have the same mean.

Suppose that X is a random variable with $\mathbb{E}(|X|) < \infty$. Then $\mathbb{E}[\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(X)$.

Proof

This follows immediately by letting $A = \Omega$ in the [definition](#).

The result above can often be used to compute $\mathbb{E}(X)$, by choosing the σ -algebra \mathcal{G} in a clever way. We say that we are computing $\mathbb{E}(X)$ by *conditioning on \mathcal{G}* . Our next properties are fundamental: every version of expected value must satisfy the *linearity* properties. The first part is the *additive property* and the second part is the *scaling property*.

Suppose that X and Y are random variables with $\mathbb{E}(|X|) < \infty$ and $\mathbb{E}(|Y|) < \infty$, and that $c \in \mathbb{R}$. Then

1. $\mathbb{E}(X + Y | \mathcal{G}) = \mathbb{E}(X | \mathcal{G}) + \mathbb{E}(Y | \mathcal{G})$
2. $\mathbb{E}(cX | \mathcal{G}) = c\mathbb{E}(X | \mathcal{G})$

Proof

1. Note that $\mathbb{E}(|X + Y|) \leq \mathbb{E}(|X|) + \mathbb{E}(|Y|) < \infty$ so $\mathbb{E}(X + Y | \mathcal{G})$ is defined. We show that $\mathbb{E}(X | \mathcal{G}) + \mathbb{E}(Y | \mathcal{G})$ satisfies the conditions in the [definition](#) for $\mathbb{E}(X + Y | \mathcal{G})$. Note first that $\mathbb{E}(X | \mathcal{G}) + \mathbb{E}(Y | \mathcal{G})$ is \mathcal{G} -measurable since both terms are. If $A \in \mathcal{G}$ then

$$\mathbb{E}\{\mathbb{E}(X | \mathcal{G}) + \mathbb{E}(Y | \mathcal{G}); A\} = \mathbb{E}[\mathbb{E}(X | \mathcal{G}); A] + \mathbb{E}[\mathbb{E}(Y | \mathcal{G}); A] = \mathbb{E}(X; A) + \mathbb{E}(Y; A) = \mathbb{E}(X + Y; A) \quad (4.10.4)$$

2. Note that $\mathbb{E}(|cX|) = |c|\mathbb{E}(|X|) < \infty$ so $\mathbb{E}(cX | \mathcal{G})$ is defined. We show that $c\mathbb{E}(X | \mathcal{G})$ satisfy the conditions in the [definition](#) for $\mathbb{E}(cX | \mathcal{G})$. Note first that $c\mathbb{E}(X | \mathcal{G})$ is \mathcal{G} -measurable since the second factor is. If $A \in \mathcal{G}$ then

$$\mathbb{E}[c\mathbb{E}(X | \mathcal{G}); A] = c\mathbb{E}[\mathbb{E}(X | \mathcal{G}); A] = c\mathbb{E}(X; A) = \mathbb{E}(cX; A) \quad (4.10.5)$$

The next set of properties are also fundamental to every notion of expected value. The first part is the *positive property* and the second part is the *increasing property*.

Suppose again that X and Y are random variables with $\mathbb{E}(|X|) < \infty$ and $\mathbb{E}(|Y|) < \infty$.

1. If $X \geq 0$ then $\mathbb{E}(X | \mathcal{G}) \geq 0$
2. If $X \leq Y$ then $\mathbb{E}(X | \mathcal{G}) \leq \mathbb{E}(Y | \mathcal{G})$

Proof

1. Let $A = \{\mathbb{E}(X | \mathcal{G}) < 0\}$. Note that $A \in \mathcal{G}$ and hence $\mathbb{E}(X; A) = \mathbb{E}[\mathbb{E}(X | \mathcal{G}); A]$. Since $X \geq 0$ with probability 1 we have $\mathbb{E}(X; A) \geq 0$. On the other hand, if $\mathbb{P}(A) > 0$ then $\mathbb{E}[\mathbb{E}(X | \mathcal{G}); A] < 0$ which is a contradiction. Hence we must have $\mathbb{P}(A) = 0$.
2. Note that if $X \leq Y$ then $Y - X \geq 0$. Hence by (a) and the additive property, $\mathbb{E}(Y - X | \mathcal{G}) = \mathbb{E}(Y | \mathcal{G}) - \mathbb{E}(X | \mathcal{G}) \geq 0$ so $\mathbb{E}(Y | \mathcal{G}) \geq \mathbb{E}(X | \mathcal{G})$.

The next few properties relate to the central idea that $\mathbb{E}(X | \mathcal{G})$ is the expected value of X given the information in the σ -algebra \mathcal{G} .

Suppose that X and V are random variables with $\mathbb{E}(|X|) < \infty$ and $\mathbb{E}(|XV|) < \infty$ and that V is measurable with respect to \mathcal{G} . Then $\mathbb{E}(VX | \mathcal{G}) = V\mathbb{E}(X | \mathcal{G})$.

Proof

We show that $V\mathbb{E}(X | \mathcal{G})$ satisfy the in [properties that characterize \$\mathbb{E}\(VX | \mathcal{G}\)\$](#) . First, $V\mathbb{E}(X | \mathcal{G})$ is \mathcal{G} -measurable since both factors are. If U is \mathcal{G} -measurable with $\mathbb{E}(|UVX|) < \infty$ then UV is also \mathcal{G} -measurable and hence

$$\mathbb{E}[UV\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(UVX) = \mathbb{E}[U(VX)] \quad (4.10.6)$$

Compare this result with the [scaling property](#). If V is measurable with respect to \mathcal{G} then V is like a constant in terms of the conditional expected value given \mathcal{G} . On the other hand, note that this result implies the [scaling property](#), since a constant can be viewed as a random variable, and as such, is measurable with respect to any σ -algebra. As a corollary to this result, note that if X itself is measurable with respect to \mathcal{G} then $\mathbb{E}(X | \mathcal{G}) = X$. The following result gives the other extreme.

Suppose that X is a random variable with $\mathbb{E}(|X|) < \infty$. If X and \mathcal{G} are independent then $\mathbb{E}(X | \mathcal{G}) = \mathbb{E}(X)$.

Proof

We show that $\mathbb{E}(X)$ satisfy the properties in the [definition](#) for $\mathbb{E}(X | \mathcal{G})$. First of course, $\mathbb{E}(X)$ is \mathcal{G} -measurable as a constant random variable. If $A \in \mathcal{G}$ then X and 1_A are independent and hence

$$\mathbb{E}(X; A) = \mathbb{E}(X)\mathbb{P}(A) = \mathbb{E}[\mathbb{E}(X); A] \quad (4.10.7)$$

Every random variable X is independent of the trivial σ -algebra $\{\emptyset, \Omega\}$ so it follows that $\mathbb{E}(X | \{\emptyset, \Omega\}) = \mathbb{E}(X)$.

The next properties are *consistency conditions*, also known as the *tower properties*. When conditioning twice, with respect to nested σ -algebras, the smaller one (representing the least amount of information) always prevails.

Suppose that X is a random variable with $\mathbb{E}(|X|) < \infty$ and that \mathcal{H} is a sub σ -algebra of \mathcal{G} . Then

1. $\mathbb{E}[\mathbb{E}(X | \mathcal{H}) | \mathcal{G}] = \mathbb{E}(X | \mathcal{H})$
2. $\mathbb{E}[\mathbb{E}(X | \mathcal{G}) | \mathcal{H}] = \mathbb{E}(X | \mathcal{H})$

Proof

1. Note first that $\mathbb{E}(X | \mathcal{H})$ is \mathcal{H} -measurable and hence also \mathcal{G} -measurable. Thus by (7), $\mathbb{E}[\mathbb{E}(X | \mathcal{H}) | \mathcal{G}] = \mathbb{E}(X | \mathcal{H})$.
2. We show that $\mathbb{E}(X | \mathcal{H})$ satisfies the conditions in the [definition](#) for $\mathbb{E}[\mathbb{E}(X | \mathcal{G}) | \mathcal{H}]$. Note again that $\mathbb{E}(X | \mathcal{H})$ is \mathcal{H} -measurable. If $A \in \mathcal{H}$ then $A \in \mathcal{G}$ and hence

$$\mathbb{E}[\mathbb{E}(X | \mathcal{G}); A] = \mathbb{E}(X; A) = \mathbb{E}[\mathbb{E}(X | \mathcal{H}); A] \quad (4.10.8)$$

The next result gives *Jensen's inequality* for conditional expected value, named for Johan Jensen.

Suppose that X takes values in an interval $S \subseteq \mathbb{R}$ and that $g: S \rightarrow \mathbb{R}$ is convex. If $\mathbb{E}(|X|) < \infty$ and $\mathbb{E}(|g(X)|) < \infty$ then

$$\mathbb{E}[g(X) | \mathcal{G}] \geq g[\mathbb{E}(X | \mathcal{G})] \quad (4.10.9)$$

Proof

As with Jensen's inequality for ordinary expected value, the best proof uses the characterization of convex functions in terms of *supporting lines*: For each $t \in S$ there exist numbers a and b (depending on t) such that

- $a + bt = g(t)$
- $a + bx \leq g(x)$ for $x \in S$

A convex function and several supporting lines

Random variables X and $\mathbb{E}(X | \mathcal{G})$ takes values in S . We can construct a *random* supporting line at $\mathbb{E}(X | \mathcal{G})$. That is, there exist random variables A and B , measurable with respect to \mathcal{G} , such that

1. $A + B\mathbb{E}(X | \mathcal{G}) = g[\mathbb{E}(X | \mathcal{G})]$
2. $A + BX \leq g(X)$

We take conditional expected value through the inequality in (b) and then use properties of conditional expected value and property (a):

$$\mathbb{E}[g(X) | \mathcal{G}] \geq \mathbb{E}(A + BX | \mathcal{G}) = A + B\mathbb{E}(X | \mathcal{G}) = g[\mathbb{E}(X | \mathcal{G})] \quad (4.10.10)$$

Note that the second step uses the fact that A and B are measurable with respect to \mathcal{G} .

Conditional Probability

For our next discussion, suppose as usual that \mathcal{G} is a sub σ -algebra of \mathcal{F} . The conditional probability of an event A given \mathcal{G} can be defined as a special case of conditional expected value. As usual, let $\mathbf{1}_A$ denote the indicator random variable of A .

For $A \in \mathcal{F}$ we define

$$\mathbb{P}(A | \mathcal{G}) = \mathbb{E}(\mathbf{1}_A | \mathcal{G}) \quad (4.10.11)$$

Thus, we have the following characterizations of conditional probability, which are special cases of the [definition](#) and the [alternate version](#):

If $A \in \mathcal{F}$ then $\mathbb{P}(A | \mathcal{G})$ is characterized (up to equivalence) by the following properties

1. $\mathbb{P}(A | \mathcal{G})$ is measurable with respect to \mathcal{G} .
2. If $B \in \mathcal{G}$ then $\mathbb{E}[\mathbb{P}(A | \mathcal{G}); B] = \mathbb{P}(A \cap B)$

Proof

For part (b), note that

$$\mathbb{E}[\mathbf{1}_B \mathbb{P}(A | \mathcal{G})] = \mathbb{E}[\mathbf{1}_B \mathbb{E}(\mathbf{1}_A | \mathcal{G})] = \mathbb{E}(\mathbf{1}_A \mathbf{1}_B) = \mathbb{E}(\mathbf{1}_{A \cap B}) = \mathbb{P}(A \cap B) \quad (4.10.12)$$

If $A \in \mathcal{F}$ then $\mathbb{P}(A | \mathcal{G})$ is characterized (up to equivalence) by the following properties

1. $\mathbb{P}(A | \mathcal{G})$ is measurable with respect to \mathcal{G} .
2. If U is measurable with respect to \mathcal{G} and $\mathbb{E}(|U|) < \infty$ then $\mathbb{E}[U \mathbb{P}(A | \mathcal{G})] = \mathbb{E}(U; A)$

The properties above for conditional expected value, of course, have special cases for conditional probability. In particular, we can compute the probability of an event by *conditioning* on a σ -algebra:

If $A \in \mathcal{F}$ then $\mathbb{P}(A) = \mathbb{E}[\mathbb{P}(A | \mathcal{G})]$.

Proof

This is a direct result of the [mean property](#) since $\mathbb{E}(\mathbf{1}_A) = \mathbb{P}(A)$.

Again, the last theorem is often a good way to compute $\mathbb{P}(A)$ when we know the conditional probability of A given \mathcal{G} . This is a very compact and elegant version of the law of total probability given first in the section on Conditional Probability in the chapter on Probability Spaces and later in the section on Discrete Distributions in the Chapter on Distributions. The following theorem gives the conditional version of the axioms of probability.

The following properties hold (as usual, modulo equivalence):

1. $\mathbb{P}(A | \mathcal{G}) \geq 0$ for every $A \in \mathcal{F}$
2. $\mathbb{P}(\Omega | \mathcal{G}) = 1$
3. If $\{A_i : i \in I\}$ is a countable disjoint subset of \mathcal{F} then $\mathbb{P}(\bigcup_{i \in I} A_i | \mathcal{G}) = \sum_{i \in I} \mathbb{P}(A_i | \mathcal{G})$

Proof

1. This is a direct consequence of (6).
2. This is trivial since $\mathbf{1}_\Omega = 1$.
3. We show that the right side satisfies the conditions in (11) that define the left side. Note that $\sum_{i \in I} \mathbb{P}(A_i | \mathcal{G})$ is \mathcal{G} -measurable since each term in the sum has this property. Let $B \in \mathcal{G}$. then

$$\mathbb{E}\left[\sum_{i \in I} \mathbb{P}(A_i | \mathcal{G}); B\right] = \sum_{i \in I} \mathbb{E}[\mathbb{P}(A_i | \mathcal{G}); B] = \sum_{i \in I} \mathbb{P}(A_i \cap B) = \mathbb{P}\left(B \cap \bigcup_{i \in I} A_i\right) \quad (4.10.13)$$

From the last result, it follows that other standard probability rules hold for conditional probability given \mathcal{G} (as always, modulo equivalence). These results include

- the complement rule

- the increasing property
- Boole's inequality
- Bonferroni's inequality
- the inclusion-exclusion laws

However, it is not correct to state that $A \mapsto \mathbb{P}(A | \mathcal{G})$ is a probability measure, because the conditional probabilities are only defined up to equivalence, and so the mapping does not make sense. We would have to specify a particular version of $\mathbb{E}(A | \mathcal{G})$ for each $A \in \mathcal{F}$ for the mapping to make sense. Even if we do this, the mapping may not define a probability measure. In part (c), the left and right sides are random variables and the equation is an event that has probability 1. However this event depends on the collection $\{A_i : i \in I\}$. In general, there will be uncountably many such collections in \mathcal{F} , and the intersection of all of the corresponding events may well have probability less than 1 (if it's measurable at all). It turns out that if the underlying probability space $(\Omega, \mathcal{F}, \mathbb{P})$ is sufficiently "nice" (and most probability spaces that arise in applications are nice), then there does in fact exist a *regular conditional probability*. That is, for each $A \in \mathcal{F}$, there exists a random variable $\mathbb{P}(A | \mathcal{G})$ satisfying the conditions in (12) and such that with probability 1, $A \mapsto \mathbb{P}(A | \mathcal{G})$ is a probability measure.

The following theorem gives a version of *Bayes' theorem*, named for the inimitable Thomas Bayes.

Suppose that $A \in \mathcal{G}$ and $B \in \mathcal{F}$. then

$$\mathbb{P}(A | B) = \frac{\mathbb{E}[\mathbb{P}(B | \mathcal{G}); A]}{\mathbb{E}[\mathbb{P}(B | \mathcal{G})]} \quad (4.10.14)$$

Proof

The proof is absolutely trivial. By definition of conditional probability given \mathcal{G} , the numerator is $\mathbb{P}(A \cap B)$ and the denominator is $\mathbb{P}(B)$. Nonetheless, Bayes' theorem is useful in settings where the expected values in the numerator and denominator can be computed directly

Basic Examples

The purpose of this discussion is to tie the general notions of conditional expected value that we are studying here to the more elementary concepts that you have seen before. Suppose that A is an event (that is, a member of \mathcal{F}) with $\mathbb{P}(A) > 0$. If B is another event, then of course, the conditional probability of B given A is

$$\mathbb{P}(B | A) = \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(A)} \quad (4.10.15)$$

If X is a random variable then the conditional distribution of X given A is the probability measure on \mathbb{R} given by

$$R \mapsto \mathbb{P}(X \in R | A) = \frac{\mathbb{P}(\{X \in R\} \cap A)}{\mathbb{P}(A)} \text{ for measurable } R \subseteq \mathbb{R} \quad (4.10.16)$$

If $\mathbb{E}(|X|) < \infty$ then the *conditional expected value* of X given A , denoted $\mathbb{E}(X | A)$, is simply the mean of this conditional distribution.

Suppose now that $\mathcal{A} = \{A_i : i \in I\}$ is a countable partition of the sample space Ω into events with positive probability. To review the jargon, $\mathcal{A} \subseteq \mathcal{F}$; the index set I is countable; $A_i \cap A_j = \emptyset$ for distinct $i, j \in I$; $\bigcup_{i \in I} A_i = \Omega$; and $\mathbb{P}(A_i) > 0$ for $i \in I$. Let $\mathcal{G} = \sigma(\mathcal{A})$, the σ -algebra generated by \mathcal{A} . The elements of \mathcal{G} are of the form $\bigcup_{j \in J} A_j$ for $J \subseteq I$. Moreover, the random variables that are measurable with respect to \mathcal{G} are precisely the variables that are constant on A_i for each $i \in I$. The σ -algebra \mathcal{G} is said to be *countably generated*.

If $B \in \mathcal{F}$ then $\mathbb{P}(B | \mathcal{G})$ is the random variable whose value on A_i is $\mathbb{P}(B | A_i)$ for each $i \in I$.

Proof

Let U denote the random variable that takes the value $\mathbb{P}(B | A_i)$ on A_i for each $i \in I$. First, U is measurable with respect to \mathcal{G} since U is constant on A_i for each $i \in I$. So we just need to show that $\mathbb{E}(U; A) = \mathbb{P}(A \cap B)$ for each $A \in \mathcal{G}$. Thus, let $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$. Then

$$\mathbb{E}(U; A) = \sum_{j \in J} \mathbb{E}(U; A_j) = \sum_{j \in J} \mathbb{P}(B | A_j) \mathbb{P}(A_j) = \mathbb{P}(A \cap B) \quad (4.10.17)$$

In this setting, the version of Bayes' theorem in (15) reduces to the usual elementary formulation: For $i \in I$, $\mathbb{E}[\mathbb{P}(B | \mathcal{G}); A_i] = \mathbb{P}(A_i) \mathbb{P}(B | A_i)$ and $\mathbb{E}[\mathbb{P}(B | \mathcal{G})] = \sum_{j \in I} \mathbb{P}(A_j) \mathbb{P}(B | A_j)$. Hence

$$\mathbb{P}(A_i | B) = \frac{\mathbb{P}(A_i) \mathbb{P}(B | A_i)}{\sum_{j \in I} \mathbb{P}(A_j) \mathbb{P}(B | A_j)} \quad (4.10.18)$$

If X is a random variable with $\mathbb{E}(|X|) < \infty$, then $\mathbb{E}(X | \mathcal{G})$ is the random variable whose value on A_i is $\mathbb{E}(X | A_i)$ for each $i \in I$.

Proof

Let U denote the random variable that takes the value $\mathbb{E}(X | A_i)$ on A_i for each $i \in I$. First, U is measurable with respect to \mathcal{G} since U is constant on A_i for each $i \in I$. So we just need to show that $\mathbb{E}(U; A) = \mathbb{E}(X; A)$ for each $A \in \mathcal{G}$. Thus, let $A = \bigcup_{j \in J} A_j$ where $J \subseteq I$. Then

$$\mathbb{E}(U; A) = \sum_{j \in J} \mathbb{E}(U; A_j) = \sum_{j \in J} \mathbb{E}(X | A_j) \mathbb{P}(A_j) = \mathbb{E}(X; A) \quad (4.10.19)$$

The previous examples would apply to $\mathcal{G} = \sigma(Y)$ if Y is a discrete random variable taking values in a countable set T . In this case, the partition is simply $\mathcal{A} = \{\{Y = y\} : y \in T\}$. On the other hand, suppose that Y is a random variable taking values in a general set T with σ -algebra \mathcal{T} . The real-valued random variables that are measurable with respect to $\mathcal{G} = \sigma(Y)$ are (up to equivalence) the measurable, real-valued functions of Y .

Specializing further, Suppose that X takes values in $S \subseteq \mathbb{R}$, Y takes values in $T \subseteq \mathbb{R}^n$ (where S and T are Lebesgue measurable) and that (X, Y) has a joint continuous distribution with probability density function f . Then Y has probability density function h given by

$$h(y) = \int_S f(x, y) dx, \quad y \in T \quad (4.10.20)$$

Assume that $h(y) > 0$ for $y \in T$. Then for $y \in T$, a conditional probability density function of X given $Y = y$ is defined by

$$g(x | y) = \frac{f(x, y)}{h(y)}, \quad x \in S \quad (4.10.21)$$

This is precisely the setting of our elementary discussion of conditional expected value. If $\mathbb{E}(|X|) < \infty$ then we usually write $\mathbb{E}(X | Y)$ instead of the clunkier $\mathbb{E}[X | \sigma(Y)]$.

In this setting above suppose that $\mathbb{E}(|X|) < \infty$. Then

$$\mathbb{E}(X | Y) = \int_S x g(x | Y) dx \quad (4.10.22)$$

Proof

Once again, we show that the integral on the right satisfies the properties in the [definition](#) for $\mathbb{E}(X | Y) = \mathbb{E}[X | \sigma(Y)]$. First, $y \mapsto \int_S x g(x | y) dx$ is measurable as a function from T into \mathbb{R} and hence the random variable $\int_S x g(x | Y) dx$ is a measurable function of Y and so is measurable with respect to $\sigma(Y)$. Next suppose that $B \in \sigma(Y)$. Then $B = \{Y \in A\}$ for some $A \in \mathcal{F}$. Then

$$\begin{aligned} \mathbb{E} \left[\int_S x g(x | Y) dx; B \right] &= \mathbb{E} \left[\int_S x g(x | Y) dx; Y \in A \right] \\ &= \mathbb{E} \left[\int_S x \frac{f(x, y)}{h(y)} dx; Y \in A \right] = \int_A \int_S x \frac{f(x, y)}{h(y)} h(y) dx dy \\ &= \int_{S \times A} x f(x, y) d(x, y) = \mathbb{E}(X; Y \in A) = \mathbb{E}(X; B) \end{aligned}$$

Best Predictor

In our elementary treatment of conditional expected value, we showed that the conditional expected value of a real-valued random variable X given a general random variable Y is the best predictor of X , in the least squares sense, among all real-valued functions of Y . A more careful statement is that $\mathbb{E}(X | Y)$ is the best predictor of X among all real-valued random variables that are *measurable* with respect to $\sigma(Y)$. Thus, it should come as not surprise that if \mathcal{G} is a sub σ -algebra of \mathcal{F} , then $\mathbb{E}(X | \mathcal{G})$ is the best predictor of X , in the least squares sense, among all real-valued random variables that are measurable with respect to \mathcal{G} . We will show that this is indeed the case in this subsection. The proofs are very similar to the ones given in the elementary section. For the rest of this discussion, we assume that \mathcal{G} is a sub σ -algebra of \mathcal{F} and that all random variables mentioned are real valued.

Suppose that X and U are random variables with $\mathbb{E}(|X|) < \infty$ and $\mathbb{E}(|XU|) < \infty$ and that U is measurable with respect to \mathcal{G} . Then $X - \mathbb{E}(X | \mathcal{G})$ and U are uncorrelated.

Proof

Note that $X - \mathbb{E}(X | \mathcal{G})$ has mean 0 by the [mean property](#). Using the [properties that characterize](#) $\mathbb{E}(X | \mathcal{G})$ we have

$$\text{cov}[X - \mathbb{E}(X | \mathcal{G}), U] = \mathbb{E}[U[X - \mathbb{E}(X | \mathcal{G})]] = \mathbb{E}(UX) - \mathbb{E}[U\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(UX) - \mathbb{E}(UX) = 0 \quad (4.10.23)$$

The next result is the main one: $\mathbb{E}(X | \mathcal{G})$ is closer to X in the mean square sense than any other random variable that is measurable with respect to \mathcal{G} . Thus, if \mathcal{G} represents the information that we have, then $\mathbb{E}(X | \mathcal{G})$ is the best we can do in estimating X .

Suppose that X and U are random variables with $\mathbb{E}(X^2) < \infty$ and $\mathbb{E}(U^2) < \infty$ and that U is measurable with respect to \mathcal{G} . Then

1. $\mathbb{E}([X - \mathbb{E}(X | \mathcal{G})]^2) \leq \mathbb{E}([X - U]^2)$.
2. Equality holds if and only if $\mathbb{P}[U = \mathbb{E}(X | \mathcal{G})] = 1$, so U and $\mathbb{E}(X | \mathcal{G})$ are equivalent.

Proof

1. Note that

$$\mathbb{E}([X - U]^2) = \mathbb{E}([X - \mathbb{E}(X | \mathcal{G}) + \mathbb{E}(X | \mathcal{G}) - U]^2) \quad (4.10.24)$$

$$= \mathbb{E}([X - \mathbb{E}(X | \mathcal{G})]^2) + 2\mathbb{E}([X - \mathbb{E}(X | \mathcal{G})][\mathbb{E}(X | \mathcal{G}) - U]) + \mathbb{E}([\mathbb{E}(X | \mathcal{G}) - U]^2) \quad (4.10.25)$$

By [mean property](#), $X - \mathbb{E}(X | \mathcal{G})$ has mean 0, so the middle term in the displayed equation is $2\text{cov}[X - \mathbb{E}(X | \mathcal{G}), \mathbb{E}(X | \mathcal{G}) - U]$. But $\mathbb{E}(X | \mathcal{G}) - U$ is \mathcal{G} -measurable and hence this covariance is 0 by [uncorrelated property](#). Therefore

$$\mathbb{E}([X - U]^2) = \mathbb{E}([X - \mathbb{E}(X | \mathcal{G})]^2) + \mathbb{E}([\mathbb{E}(X | \mathcal{G}) - U]^2) \geq \mathbb{E}([X - \mathbb{E}(X | \mathcal{G})]^2) \quad (4.10.26)$$

2. Equality holds if and only if $\mathbb{E}([\mathbb{E}(X | \mathcal{G}) - U]^2) = 0$ if and only if $\mathbb{P}[U = \mathbb{E}(X | \mathcal{G})] = 1$

Conditional Variance

Once again, we assume that \mathcal{G} is a sub σ -algebra of \mathcal{F} and that all random variables mentioned are real valued, unless otherwise noted. It's natural to define the conditional variance of a random variable given \mathcal{G} in the same way as ordinary variance, but with all expected values conditioned on \mathcal{G} .

Suppose that X is a random variable with $\mathbb{E}(X^2) < \infty$. The *conditional variance* of X given \mathcal{G} is

$$\text{var}(X | \mathcal{G}) = \mathbb{E} \left([X - \mathbb{E}(X | \mathcal{G})]^2 \middle| \mathcal{G} \right) \quad (4.10.27)$$

Like all conditional expected values relative to \mathcal{G} , $\text{var}(X | \mathcal{G})$ is a random variable that is measurable with respect to \mathcal{G} and is unique up to equivalence. The first property is analogous to the computational formula for ordinary variance.

Suppose again that X is a random variable with $\mathbb{E}(X^2) < \infty$. Then

$$\text{var}(X | \mathcal{G}) = \mathbb{E}(X^2 | \mathcal{G}) - [\mathbb{E}(X | \mathcal{G})]^2 \quad (4.10.28)$$

Proof

Expanding the square in the definition and using basic properties of conditional expectation, we have

$$\text{var}(X | \mathcal{G}) = \mathbb{E}(X^2 - 2X\mathbb{E}(X | \mathcal{G}) + [\mathbb{E}(X | \mathcal{G})]^2 | \mathcal{G}) = \mathbb{E}(X^2 | \mathcal{G}) - 2\mathbb{E}[X\mathbb{E}(X | \mathcal{G}) | \mathcal{G}] + \mathbb{E}([\mathbb{E}(X | \mathcal{G})]^2 | \mathcal{G}) \quad (4.10.29)$$

$$= \mathbb{E}(X^2 | \mathcal{G}) - 2\mathbb{E}(X | \mathcal{G})\mathbb{E}(X | \mathcal{G}) + [\mathbb{E}(X | \mathcal{G})]^2 = \mathbb{E}(X^2 | \mathcal{G}) - [\mathbb{E}(X | \mathcal{G})]^2 \quad (4.10.30)$$

Next is a formula for the ordinary variance in terms of conditional variance and expected value.

Suppose again that X is a random variable with $\mathbb{E}(X^2) < \infty$. Then

$$\text{var}(X) = \mathbb{E}[\text{var}(X | \mathcal{G})] + \text{var}[\mathbb{E}(X | \mathcal{G})] \quad (4.10.31)$$

Proof

From the previous theorem and properties of conditional expected value we have $\mathbb{E}[\text{var}(X | \mathcal{G})] = \mathbb{E}(X^2) - \mathbb{E}([\mathbb{E}(X | \mathcal{G})]^2)$. But $\mathbb{E}(X^2) = \text{var}(X) + [\mathbb{E}(X)]^2$ and similarly, $\mathbb{E}([\mathbb{E}(X | \mathcal{G})]^2) = \text{var}[\mathbb{E}(X | \mathcal{G})] + (\mathbb{E}[\mathbb{E}(X | \mathcal{G})])^2$. But also, $\mathbb{E}[\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(X)$ so substituting we get $\mathbb{E}[\text{var}(X | \mathcal{G})] = \text{var}(X) - \text{var}[\mathbb{E}(X | \mathcal{G})]$.

So the variance of X is the expected conditional variance plus the variance of the conditional expected value. This result is often a good way to compute $\text{var}(X)$ when we know the conditional distribution of X given \mathcal{G} . In turn, this property leads to a formula for the mean square error when $\mathbb{E}(X | \mathcal{G})$ is thought of as a predictor of X .

Suppose again that X is a random variable with $\mathbb{E}(X^2) < \infty$.

$$\mathbb{E}([X - \mathbb{E}(X | \mathcal{G})]^2) = \text{var}(X) - \text{var}[\mathbb{E}(X | \mathcal{G})] \quad (4.10.32)$$

Proof

From the [definition](#) and from the [mean property](#) and [variance formula](#),

$$\mathbb{E}([X - \mathbb{E}(X | \mathcal{G})]^2) = \mathbb{E}[\text{var}(X | \mathcal{G})] = \text{var}(X) - \text{var}[\mathbb{E}(X | \mathcal{G})] \quad (4.10.33)$$

Let us return to the study of predictors of the real-valued random variable X , and compare them in terms of mean square error.

Suppose again that X is a random variable with $\mathbb{E}(X^2) < \infty$.

1. The best constant predictor of X is $\mathbb{E}(X)$ with mean square error $\text{var}(X)$.
2. If Y is another random variable with $\mathbb{E}(Y^2) < \infty$, then the best predictor of X among linear functions of Y is

$$L(X | Y) = \mathbb{E}(X) + \frac{\text{cov}(X, Y)}{\text{var}(Y)}[Y - \mathbb{E}(Y)] \quad (4.10.34)$$

with mean square error $\text{var}(X)[1 - \text{cor}^2(X, Y)]$.

3. If Y is a (general) random variable, then the best predictor of X among all real-valued functions of Y with finite variance is $\mathbb{E}(X | Y)$ with mean square error $\text{var}(X) - \text{var}[\mathbb{E}(X | Y)]$.
4. If \mathcal{G} is a sub σ -algebra of \mathcal{F} , then the best predictor of X among random variables with finite variance that are measurable with respect to \mathcal{G} is $\mathbb{E}(X | \mathcal{G})$ with mean square error $\text{var}(X) - \text{var}[\mathbb{E}(X | \mathcal{G})]$.

Of course, (a) is a special case of (d) with $\mathcal{G} = \{\emptyset, \Omega\}$ and (c) is a special case of (d) with $\mathcal{G} = \sigma(Y)$. Only (b), the linear case, cannot be interpreted in terms of conditioning with respect to a σ -algebra.

Conditional Covariance

Suppose again that \mathcal{G} is a sub σ -algebra of \mathcal{F} . The conditional covariance of two random variables is defined like the ordinary covariance, but with all expected values conditioned on \mathcal{G} .

Suppose that X and Y are random variables with $\mathbb{E}(X^2) < \infty$ and $\mathbb{E}(Y^2) < \infty$. The *conditional covariance* of X and Y given \mathcal{G} is defined as

$$\text{cov}(X, Y | \mathcal{G}) = \mathbb{E}\left([X - \mathbb{E}(X | \mathcal{G})][Y - \mathbb{E}(Y | \mathcal{G})] | \mathcal{G}\right) \quad (4.10.35)$$

So $\text{cov}(X, Y | \mathcal{G})$ is a random variable that is measurable with respect to \mathcal{G} and is unique up to equivalence. As should be the case, conditional covariance generalizes conditional variance.

Suppose that X is a random variable with $\mathbb{E}(X^2) < \infty$. Then $\text{cov}(X, X | \mathcal{G}) = \text{var}(X | \mathcal{G})$.

Proof

This follows immediately from the two definitions.

Our next result is a computational formula that is analogous to the one for standard covariance—the covariance is the mean of the product minus the product of the means, but now with all expected values conditioned on \mathcal{G} :

Suppose again that X and Y are random variables with $\mathbb{E}(X^2) < \infty$ and $\mathbb{E}(Y^2) < \infty$. Then

$$\text{cov}(X, Y | \mathcal{G}) = \mathbb{E}(XY | \mathcal{G}) - \mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G}) \quad (4.10.36)$$

Proof

Expanding the product in the definition and using basic properties of conditional expectation, we have

$$\text{cov}(X, Y | \mathcal{G}) = \mathbb{E} \left(XY - X\mathbb{E}(Y | \mathcal{G}) - Y\mathbb{E}(X | \mathcal{G}) + \mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G}) \mid \mathcal{G} \right) = \mathbb{E}(XY | \mathcal{G}) - \mathbb{E}[X\mathbb{E}(Y | \mathcal{G}) | \mathcal{G}] - \mathbb{E}[Y\mathbb{E}(X | \mathcal{G}) | \mathcal{G}] \quad (4.10.37)$$

$$= \mathbb{E}(XY | \mathcal{G}) - \mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G}) - \mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G}) + \mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G}) = \mathbb{E}(XY | \mathcal{G}) - \mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G}) \quad (4.10.38)$$

Our next result shows how to compute the ordinary covariance of X and Y by *conditioning on X* .

Suppose again that X and Y are random variables with $\mathbb{E}(X^2) < \infty$ and $\mathbb{E}(Y^2) < \infty$. Then

$$\text{cov}(X, Y) = \mathbb{E}[\text{cov}(X, Y | \mathcal{G})] + \text{cov}[\mathbb{E}(X | \mathcal{G}), \mathbb{E}(Y | \mathcal{G})] \quad (4.10.39)$$

Proof

From (29) and properties of conditional expected value we have

$$\mathbb{E}[\text{cov}(X, Y | \mathcal{G})] = \mathbb{E}(XY) - \mathbb{E}[\mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G})] \quad (4.10.40)$$

But $\mathbb{E}(XY) = \text{cov}(X, Y) + \mathbb{E}(X)\mathbb{E}(Y)$ and similarly,

$$\mathbb{E}[\mathbb{E}(X | \mathcal{G})\mathbb{E}(Y | \mathcal{G})] = \text{cov}[\mathbb{E}(X | \mathcal{G}), \mathbb{E}(Y | \mathcal{G})] + \mathbb{E}[\mathbb{E}(X | \mathcal{G})]\mathbb{E}[\mathbb{E}(Y | \mathcal{G})] \quad (4.10.41)$$

But also, $\mathbb{E}[\mathbb{E}(X | \mathcal{G})] = \mathbb{E}(X)$ and $\mathbb{E}[\mathbb{E}(Y | \mathcal{G})] = \mathbb{E}(Y)$ so substituting we get

$$\mathbb{E}[\text{cov}(X, Y | \mathcal{G})] = \text{cov}(X, Y) - \text{cov}[\mathbb{E}(X | \mathcal{G}), \mathbb{E}(Y | \mathcal{G})] \quad (4.10.42)$$

Thus, the covariance of X and Y is the expected conditional covariance plus the covariance of the conditional expected values. This result is often a good way to compute $\text{cov}(X, Y)$ when we know the conditional distribution of (X, Y) given \mathcal{G} .

4.11: Vector Spaces of Random Variables

Basic Theory

Many of the concepts in this chapter have elegant interpretations if we think of real-valued random variables as vectors in a vector space. In particular, variance and higher moments are related to the concept of norm and distance, while covariance is related to inner product. These connections can help unify and illuminate some of the ideas in the chapter from a different point of view. Of course, real-valued random variables are simply measurable, real-valued functions defined on the sample space, so much of the discussion in this section is a special case of our discussion of function spaces in the chapter on Distributions, but recast in the notation of probability.

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Thus, Ω is the set of outcomes, \mathcal{F} is the σ -algebra of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . Our basic *vector space* \mathcal{V} consists of all real-valued random variables defined on $(\Omega, \mathcal{F}, \mathbb{P})$ (that is, defined for the experiment). Recall that random variables X_1 and X_2 are equivalent if $\mathbb{P}(X_1 = X_2) = 1$, in which case we write $X_1 \equiv X_2$. We consider two such random variables as the same vector, so that technically, our vector space consists of *equivalence classes* under this equivalence relation. The *addition operator* corresponds to the usual addition of two real-valued random variables, and the operation of *scalar multiplication* corresponds to the usual multiplication of a real-valued random variable by a real (non-random) number. These operations are compatible with the equivalence relation in the sense that if $X_1 \equiv X_2$ and $Y_1 \equiv Y_2$ then $X_1 + Y_1 \equiv X_2 + Y_2$ and $cX_1 \equiv cX_2$ for $c \in \mathbb{R}$. In short, the vector space \mathcal{V} is well-defined.

Norm

Suppose that $k \in [1, \infty)$. The k norm of $X \in \mathcal{V}$ is defined by

$$\|X\|_k = \left[\mathbb{E}(|X|^k) \right]^{1/k} \quad (4.11.1)$$

Thus, $\|X\|_k$ is a measure of the size of X in a certain sense, and of course it's possible that $\|X\|_k = \infty$. The following theorems establish the fundamental properties. The first is the *positive property*.

Suppose again that $k \in [1, \infty)$. For $X \in \mathcal{V}$,

1. $\|X\|_k \geq 0$
2. $\|X\|_k = 0$ if and only if $\mathbb{P}(X = 0) = 1$ (so that $X \equiv 0$).

Proof

These results follow from the basic inequality properties of expected value. First $|X|^k \geq 0$ with probability 1, so $\mathbb{E}(|X|^k) \geq 0$. In addition, $\mathbb{E}(|X|^k) = 0$ if and only if $\mathbb{P}(X = 0) = 1$.

The next result is the *scaling property*.

Suppose again that $k \in [1, \infty)$. Then $\|cX\|_k = |c| \|X\|_k$ for $X \in \mathcal{V}$ and $c \in \mathbb{R}$.

Proof

$$\|cX\|_k = \left[\mathbb{E}(|cX|^k) \right]^{1/k} = \left[\mathbb{E}(|c|^k |X|^k) \right]^{1/k} = \left[|c|^k \mathbb{E}(|X|^k) \right]^{1/k} = |c| \left[\mathbb{E}(|X|^k) \right]^{1/k} = |c| \|X\|_k \quad (4.11.2)$$

The next result is *Minkowski's inequality*, named for Hermann Minkowski, and also known as the *triangle inequality*.

Suppose again that $k \in [1, \infty)$. Then $\|X + Y\|_k \leq \|X\|_k + \|Y\|_k$ for $X, Y \in \mathcal{V}$.

Proof

The first quadrant $S = \{(x, y) \in \mathbb{R}^2 : x \geq 0, y \geq 0\}$ is a convex set and $g(x, y) = (x^{1/k} + y^{1/k})^k$ is concave on S . From Jensen's inequality, if U and V are nonnegative random variables, then

$$\mathbb{E} \left[(U^{1/k} + V^{1/k})^k \right] \leq \left([\mathbb{E}(U)]^{1/k} + [\mathbb{E}(V)]^{1/k} \right)^k \quad (4.11.3)$$

Letting $U = |X|^k$ and $V = |Y|^k$ and simplifying gives the result. To show that g really is concave on S , we can compute the second partial derivatives. Let $h(x, y) = x^{1/k} + y^{1/k}$ so that $g = h^k$. Then

$$g_{xx} = \frac{k-1}{k} h^{k-2} x^{1/k-2} (x^{1/k} - h) \quad (4.11.4)$$

$$g_{yy} = \frac{k-1}{k} h^{k-2} y^{1/k-2} (y^{1/k} - h) \quad (4.11.5)$$

$$g_{xy} = \frac{k-1}{k} h^{k-2} x^{1/k-1} y^{1/k-1} \quad (4.11.6)$$

Clearly $h(x, y) \geq x^{1/k}$ and $h(x, y) \geq y^{1/k}$ for $x \geq 0$ and $y \geq 0$, so g_{xx} and g_{yy} , the diagonal entries of the second derivative matrix, are nonpositive on S . A little algebra shows that the determinant of the second derivative matrix $g_{xx}g_{yy} - g_{xy}^2 = 0$ on S . Thus, the second derivative matrix of g is negative semi-definite.

It follows from the last three results that the set of random variables (again, modulo equivalence) with finite k norm forms a *subspace* of our parent vector space \mathcal{V} , and that the k norm really is a norm on this vector space.

For $k \in [1, \infty)$, \mathcal{L}_k denotes the vector space of $X \in \mathcal{V}$ with $\|X\|_k < \infty$, and with norm $\|\cdot\|_k$.

In analysis, p is often used as the index rather than k as we have used here, but p seems too much like a probability, so we have broken with tradition on this point. The \mathcal{L} is in honor of Henri Lebesgue, who developed much of this theory. Sometimes, when we need to indicate the dependence on the underlying σ -algebra \mathcal{F} , we write $\mathcal{L}_k(\mathcal{F})$. Our next result is *Lyapunov's inequality*, named for Aleksandr Lyapunov. This inequality shows that the k -norm of a random variable is increasing in k .

Suppose that $j, k \in [1, \infty)$ with $j \leq k$. Then $\|X\|_j \leq \|X\|_k$ for $X \in \mathcal{V}$.

Proof

Note that $S = \{x \in \mathbb{R} : x \geq 0\}$ is convex and $g(x) = x^{k/j}$ is convex on S . From Jensen's inequality, if U is a nonnegative random variable then $[\mathbb{E}(U)]^{k/j} \leq \mathbb{E}(U^{k/j})$. Letting $U = |X|^j$ and simplifying gives the result.

Lyapunov's inequality shows that if $1 \leq j \leq k$ and $\|X\|_k < \infty$ then $\|X\|_j < \infty$. Thus, \mathcal{L}_k is a subspace of \mathcal{L}_j .

Metric

The k norm, like any norm on a vector space, can be used to define a metric, or distance function; we simply compute the norm of the difference between two vectors.

For $k \in [1, \infty)$, the k distance (or k metric) between $X, Y \in \mathcal{V}$ is defined by

$$d_k(X, Y) = \|X - Y\|_k = \left[\mathbb{E}(|X - Y|^k) \right]^{1/k} \quad (4.11.7)$$

The following properties are analogous to the properties in [norm properties](#) (and thus very little additional work is required for the proofs). These properties show that the k metric really is a metric on \mathcal{L}_k (as always, modulo equivalence). The first is the *positive property*.

Suppose again that $k \in [1, \infty)$ $X, Y \in \mathcal{V}$. Then

1. $d_k(X, Y) \geq 0$
2. $d_k(X, Y) = 0$ if and only if $\mathbb{P}(X = Y) = 1$ (so that $X \equiv Y$ and Y).

Proof

These results follow directly from the [positive property](#).

Next is the obvious *symmetry property*:

$$d_k(X, Y) = d_k(Y, X) \text{ for } X, Y \in \mathcal{V}.$$

Next is the distance version of the *triangle inequality*.

$$d_k(X, Z) \leq d_k(X, Y) + d_k(Y, Z) \text{ for } X, Y, Z \in \mathcal{V}$$

Proof

From [Minkowski's inequality](#),

$$d_k(X, Z) = \|X - Z\|_k = \|(X - Y) + (Y - Z)\|_k \leq \|X - Y\|_k + \|Y - Z\|_k = d_k(X, Y) + d_k(Y, Z) \quad (4.11.8)$$

The last three properties mean that d_k is indeed a metric on \mathcal{L}_k for $k \geq 1$. In particular, note that the standard deviation is simply the 2-distance from X to its mean $\mu = \mathbb{E}(X)$:

$$\text{sd}(X) = d_2(X, \mu) = \|X - \mu\|_2 = \sqrt{\mathbb{E}[(X - \mu)^2]} \quad (4.11.9)$$

and the variance is the square of this. More generally, the k th moment of X about a is simply the k th power of the k -distance from X to a . The 2-distance is especially important for reasons that will become clear below, in the discussion of [inner product](#). This distance is also called the *root mean square distance*.

Center and Spread Revisited

Measures of center and measures of spread are best thought of together, in the context of a *measure of distance*. For a real-valued random variable X , we first try to find the constants $t \in \mathbb{R}$ that are closest to X , as measured by the given distance; any such t is a *measure of center* relative to the distance. The minimum distance itself is the corresponding *measure of spread*.

Let us apply this procedure to the 2-distance.

For $X \in \mathcal{L}_2$, define the *root mean square error* function by

$$d_2(X, t) = \|X - t\|_2 = \sqrt{\mathbb{E}[(X - t)^2]}, \quad t \in \mathbb{R} \quad (4.11.10)$$

For $X \in \mathcal{L}_2$, $d_2(X, t)$ is minimized when $t = \mathbb{E}(X)$ and the minimum value is $\text{sd}(X)$.

Proof

Note that the minimum value of $d_2(X, t)$ occurs at the same points as the minimum value of $d_2^2(X, t) = \mathbb{E}[(X - t)^2]$ (this is the *mean square error* function). Expanding and taking expected values term by term gives

$$\mathbb{E}[(X - t)^2] = \mathbb{E}(X^2) - 2t\mathbb{E}(X) + t^2 \quad (4.11.11)$$

This is a quadratic function of t and hence the graph is a parabola opening upward. The minimum occurs at $t = \mathbb{E}(X)$, and the minimum value is $\text{var}(X)$. Hence the minimum value of $t \mapsto d_2(X, t)$ also occurs at $t = \mathbb{E}(X)$ and the minimum value is $\text{sd}(X)$.

We have seen this computation several times before. The best constant predictor of X is $\mathbb{E}(X)$, with mean square error $\text{var}(X)$. The physical interpretation of this result is that the moment of inertia of the mass distribution of X about t is minimized when $t = \mu$, the center of mass. Next, let us apply our procedure to the 1-distance.

For $X \in \mathcal{L}_1$, define the *mean absolute error* function by

$$d_1(X, t) = \|X - t\|_1 = \mathbb{E}[|X - t|], \quad t \in \mathbb{R} \quad (4.11.12)$$

We will show that $d_1(X, t)$ is minimized when t is any median of X . (Recall that the set of medians of X forms a closed, bounded interval.) We start with a discrete case, because it's easier and has special interest.

Suppose that $X \in \mathcal{L}_1$ has a discrete distribution with values in a finite set $S \subseteq \mathbb{R}$. Then $d_1(X, t)$ is minimized when t is any median of X .

Proof

Note first that $\mathbb{E}(|X - t|) = \mathbb{E}(t - X, X \leq t) + \mathbb{E}(X - t, X > t)$. Hence $\mathbb{E}(|X - t|) = a_t t + b_t$, where $a_t = 2\mathbb{P}(X \leq t) - 1$ and where $b_t = \mathbb{E}(X) - 2\mathbb{E}(X, X \leq t)$. Note that $\mathbb{E}(|X - t|)$ is a continuous, piecewise linear function of t , with corners at the values in S . That is, the function is a *linear spline*. Let m be the smallest median of X . If $t < m$ and $t \notin S$, then the slope of the linear piece at t is negative. Let M be the largest median of X . If $t > M$ and $t \notin S$, then the slope of the linear piece at t is positive. If $t \in (m, M)$ then the slope of the linear piece at t is 0. Thus $\mathbb{E}(|X - t|)$ is minimized for every t in the median interval $[m, M]$.

The last result shows that mean absolute error has a couple of basic deficiencies as a measure of error:

- The function may not be smooth (differentiable).
- The function may not have a unique minimizing value of t .

Indeed, when X does not have a unique median, there is no compelling reason to choose one value in the median interval, as the measure of center, over any other value in the interval.

Suppose now that $X \in \mathcal{L}_1$ has a general distribution on \mathbb{R} . Then $d_1(X, t)$ is minimized when t is any median of X .

Proof

Let $s, t \in \mathbb{R}$. Suppose first that $s < t$. Computing the expected value over the events $X \leq s$, $s < X \leq t$, and $X > t$, and simplifying gives

$$\mathbb{E}(|X - t|) = \mathbb{E}(|X - s|) + (t - s) [2\mathbb{P}(X \leq s) - 1] + 2\mathbb{E}(t - X, s < X \leq t) \quad (4.11.13)$$

Suppose next that $t < s$. Using similar methods gives

$$\mathbb{E}(|X - t|) = \mathbb{E}(|X - s|) + (t - s) [2\mathbb{P}(X < s) - 1] + 2\mathbb{E}(X - t, t \leq X < s) \quad (4.11.14)$$

Note that the last terms on the right in these equations are nonnegative. If we take s to be a median of X , then the middle terms on the right in the equations are also nonnegative. Hence if s is a median of X and t is any other number then $\mathbb{E}(|X - t|) \geq \mathbb{E}(|X - s|)$.

Convergence

Whenever we have a measure of distance, we automatically have a criterion for convergence.

Suppose that $X_n \in \mathcal{L}_k$ for $n \in \mathbb{N}_+$ and that $X \in \mathcal{L}_k$, where $k \in [1, \infty)$. Then $X_n \rightarrow X$ as $n \rightarrow \infty$ in k th mean if $X_n \rightarrow X$ as $n \rightarrow \infty$ in the vector space \mathcal{L}_k . That is,

$$d_k(X_n, X) = \|X_n - X\|_k \rightarrow 0 \text{ as } n \rightarrow \infty \quad (4.11.15)$$

or equivalently $\mathbb{E}(|X_n - X|^k) \rightarrow 0$ as $n \rightarrow \infty$.

When $k = 1$, we simply say that $X_n \rightarrow X$ as $n \rightarrow \infty$ in mean; when $k = 2$, we say that $X_n \rightarrow X$ as $n \rightarrow \infty$ in mean square. These are the most important special cases.

Suppose that $1 \leq j \leq k$. If $X_n \rightarrow X$ as $n \rightarrow \infty$ in k th mean then $X_n \rightarrow X$ as $n \rightarrow \infty$ in j th mean.

Proof

This follows from [Lyapunov's inequality](#). Note that $0 \leq d_j(X_n, X) \leq d_k(X_n, X) \rightarrow 0$ as $n \rightarrow \infty$.

Convergence in k th mean implies that the k norms converge.

Suppose that $X_n \in \mathcal{L}_k$ for $n \in \mathbb{N}_+$ and that $X \in \mathcal{L}_k$, where $k \in [1, \infty)$. If $X_n \rightarrow X$ as $n \rightarrow \infty$ in k th mean then $\|X_n\|_k \rightarrow \|X\|_k$ as $n \rightarrow \infty$. Equivalently, if $\mathbb{E}(|X_n - X|^k) \rightarrow 0$ as $n \rightarrow \infty$ then $\mathbb{E}(|X_n|^k) \rightarrow \mathbb{E}(|X|^k)$ as $n \rightarrow \infty$.

Proof

This is a simple consequence of the reverse triangle inequality, which holds in any normed vector space. The general result is that if a sequence of vectors in a normed vector space converge then the norms converge. In our notation here,

$$|\|X_n\|_k - \|X\|_k| \leq \|X_n - X\|_k \quad (4.11.16)$$

so if the right side converges to 0 as $n \rightarrow \infty$, then so does the left side.

The converse is not true; a [counterexample](#) is given below. Our next result shows that convergence in mean is stronger than convergence in probability.

Suppose that $X_n \in \mathcal{L}_1$ for $n \in \mathbb{N}_+$ and that $X \in \mathcal{L}_1$. If $X_n \rightarrow X$ as $n \rightarrow \infty$ in mean, then $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability.

Proof

This follows from Markov's inequality. For $\epsilon > 0$, $0 \leq \mathbb{P}(|X_n - X| > \epsilon) \leq \mathbb{E}(|X_n - X|) / \epsilon \rightarrow 0$ as $n \rightarrow \infty$.

The converse is not true. That is, convergence with probability 1 does not imply convergence in k th mean; a [counterexample](#) is given below. Also convergence in k th mean does not imply convergence with probability 1; a [counterexample](#) to this is given below. In summary, the implications in the various modes of convergence are shown below; no other implications hold in general.

- Convergence with probability 1 implies convergence in probability.
- Convergence in k th mean implies convergence in j th mean if $j \leq k$.
- Convergence in k th mean implies convergence in probability.
- Convergence in probability implies convergence in distribution.

However, the next section on uniformly integrable variables gives a condition under which convergence in probability implies convergence in mean.

Inner Product

The vector space \mathcal{L}_2 of real-valued random variables on $(\Omega, \mathcal{F}, \mathbb{P})$ (modulo equivalence of course) with finite second moment is special, because it's the only one in which the norm corresponds to an inner product.

The inner product of $X, Y \in \mathcal{L}_2$ is defined by

$$\langle X, Y \rangle = \mathbb{E}(XY) \quad (4.11.17)$$

The following results are analogous to the basic properties of covariance, and show that this definition really does give an inner product on the vector space

For $X, Y, Z \in \mathcal{L}_2$ and $a \in \mathbb{R}$,

1. $\langle X, Y \rangle = \langle Y, X \rangle$, the *symmetric property*.
2. $\langle X, X \rangle \geq 0$ and $\langle X, X \rangle = 0$ if and only if $\mathbb{P}(X = 0) = 1$ (so that $X \equiv 0$), the *positive property*.
3. $\langle aX, Y \rangle = a\langle X, Y \rangle$, the *scaling property*.
4. $\langle X + Y, Z \rangle = \langle X, Z \rangle + \langle Y, Z \rangle$, the *additive property*.

Proof

1. This property is trivial from the definition.
2. Note that $\mathbb{E}(X^2) \geq 0$ and $\mathbb{E}(X^2) = 0$ if and only if $\mathbb{P}(X = 0) = 1$.
3. This follows from the scaling property of expected value: $\mathbb{E}(aXY) = a\mathbb{E}(XY)$
4. This follows from the additive property of expected value: $\mathbb{E}[(X + Y)Z] = \mathbb{E}(XZ) + \mathbb{E}(YZ)$.

From parts (a), (c), and (d) it follows that inner product is *bi-linear*, that is, linear in each variable with the other fixed. Of course bi-linearity holds for any inner product on a vector space. Covariance and correlation can easily be expressed in terms of this inner product. The covariance of two random variables is the inner product of the corresponding *centered* variables. The correlation is the inner product of the corresponding standard scores.

For $X, Y \in \mathcal{L}_2$,

1. $\text{cov}(X, Y) = \langle X - \mathbb{E}(X), Y - \mathbb{E}(Y) \rangle$
2. $\text{cor}(X, Y) = \langle [X - \mathbb{E}(X)]/\text{sd}(X), [Y - \mathbb{E}(Y)]/\text{sd}(Y) \rangle$

Proof

1. This is simply a restatement of the definition of covariance.
2. This is a restatement of the fact that the correlation of two variables is the covariance of their corresponding standard scores.

Thus, real-valued random variables X and Y are uncorrelated if and only if the centered variables $X - \mathbb{E}(X)$ and $Y - \mathbb{E}(Y)$ are *perpendicular* or *orthogonal* as elements of \mathcal{L}_2 .

For $X \in \mathcal{L}_2$, $\langle X, X \rangle = \|X\|_2^2 = \mathbb{E}(X^2)$.

Thus, the norm associated with the inner product is the 2-norm studied above, and corresponds to the *root mean square* operation on a random variable. This fact is a fundamental reason why the 2-norm plays such a special, honored role; of all the k -norms, only the 2-norm corresponds to an inner product. In turn, this is one of the reasons that *root mean square difference* is of fundamental importance in probability and statistics. Technically, the vector space \mathcal{L}_2 is a *Hilbert space*, named for David Hilbert.

The next result is *Hölder's inequality*, named for Otto Hölder.

Suppose that $j, k \in [1, \infty)$ and $\frac{1}{j} + \frac{1}{k} = 1$. For $X \in \mathcal{L}_j$ and $Y \in \mathcal{L}_k$,

$$\langle |X|, |Y| \rangle \leq \|X\|_j \|Y\|_k \quad (4.11.18)$$

Proof

Note that $S = \{(x, y) \in \mathbb{R}^2 : x \geq 0, y \geq 0\}$ is a convex set and $g(x, y) = x^{1/j} y^{1/k}$ is concave on S . From Jensen's inequality, if U and V are nonnegative random variables then $\mathbb{E}(U^{1/j} V^{1/k}) \leq [\mathbb{E}(U)]^{1/j} [\mathbb{E}(V)]^{1/k}$. Substituting $U = |X|^j$ and $V = |Y|^k$ gives the result.

To show that g really is concave on S , we compute the second derivative matrix:

$$\begin{bmatrix} (1/j)(1/j-1)x^{1/j-2}y^{1/k} & (1/j)(1/k)x^{1/j-1}y^{1/k-1} \\ (1/j)(1/k)x^{1/j-1}y^{1/k-1} & (1/k)(1/k-1)x^{1/j}y^{1/k-2} \end{bmatrix} \quad (4.11.19)$$

Since $1/j < 1$ and $1/k < 1$, the diagonal entries are negative on S . The determinant simplifies to

$$(1/j)(1/k)x^{2/j-2}y^{2/k-2}[1 - (1/j + 1/k)] = 0 \quad (4.11.20)$$

In the context of the last theorem, j and k are called *conjugate exponents*. If we let $j = k = 2$ in Hölder's inequality, then we get the *Cauchy-Schwarz inequality*, named for Augustin Cauchy and Karl Schwarz: For $X, Y \in \mathcal{L}_2$,

$$\mathbb{E}(|X| |Y|) \leq \sqrt{\mathbb{E}(X^2)} \sqrt{\mathbb{E}(Y^2)} \quad (4.11.21)$$

In turn, the Cauchy-Schwarz inequality is equivalent to the basic inequalities for covariance and correlations: For $X, Y \in \mathcal{L}_2$,

$$|\text{cov}(X, Y)| \leq \text{sd}(X)\text{sd}(Y), \quad |\text{cor}(X, Y)| \leq 1 \quad (4.11.22)$$

If $j, k \in [1, \infty)$ are conjugate exponents then

1. $k = \frac{j}{j-1}$.
2. $k \downarrow 1$ as $j \uparrow \infty$.

The following result is an equivalent to the identity $\text{var}(X+Y) + \text{var}(X-Y) = 2[\text{var}(X) + \text{var}(Y)]$ that we studied in the section on covariance and correlation. In the context of vector spaces, the result is known as the *parallelogram rule*:

If $X, Y \in \mathcal{L}_2$ then

$$\|X+Y\|_2^2 + \|X-Y\|_2^2 = 2\|X\|_2^2 + 2\|Y\|_2^2 \quad (4.11.23)$$

Proof

This result follows from the bi-linearity of inner product:

$$\|X+Y\|_2^2 + \|X-Y\|_2^2 = \langle X+Y, X+Y \rangle + \langle X-Y, X-Y \rangle \quad (4.11.24)$$

$$= (\langle X, X \rangle + 2\langle X, Y \rangle + \langle Y, Y \rangle) + (\langle X, X \rangle - 2\langle X, Y \rangle + \langle Y, Y \rangle) = 2\|X\|^2 + 2\|Y\|^2 \quad (4.11.25)$$

The following result is equivalent to the statement that the variance of the sum of uncorrelated variables is the sum of the variances, which again we proved in the section on covariance and correlation. In the context of vector spaces, the result is the famous *Pythagorean theorem*, named for Pythagoras of course.

If (X_1, X_2, \dots, X_n) is a sequence of random variables in \mathcal{L}_2 with $\langle X_i, X_j \rangle = 0$ for $i \neq j$ then

$$\left\| \sum_{i=1}^n X_i \right\|_2^2 = \sum_{i=1}^n \|X_i\|_2^2 \quad (4.11.26)$$

Proof

Again, this follows from the bi-linearity of inner product:

$$\left\| \sum_{i=1}^n X_i \right\|_2^2 = \left\langle \sum_{i=1}^n X_i, \sum_{j=1}^n X_j \right\rangle = \sum_{i=1}^n \sum_{j=1}^n \langle X_i, X_j \rangle \quad (4.11.27)$$

The terms with $i \neq j$ are 0 by the orthogonality assumption, so

$$\left\| \sum_{i=1}^n X_i \right\|_2^2 = \sum_{i=1}^n \langle X_i, X_i \rangle = \sum_{i=1}^n \|X_i\|_2^2 \quad (4.11.28)$$

Projections

The best linear predictor studied in the section on covariance and correlation and conditional expected values have nice interpretation in terms of projections onto subspaces of \mathcal{L}_2 . First let's review the concepts. Recall that \mathcal{U} is a *subspace* of \mathcal{L}_2 if $\mathcal{U} \subseteq \mathcal{L}_2$ and \mathcal{U} is also a vector space (under the same operations of addition and scalar multiplication). To show that $\mathcal{U} \subseteq \mathcal{L}_2$ is a subspace, we just need to show the *closure properties* (the other axioms of a vector space are inherited).

- If $U, V \in \mathcal{U}$ then $U+V \in \mathcal{U}$.
- If $U \in \mathcal{U}$ and $c \in \mathbb{R}$ then $cU \in \mathcal{U}$.

Suppose now that \mathcal{U} is a subspace of \mathcal{L}_2 and that $X \in \mathcal{L}_2$. Then the *projection* of X onto \mathcal{U} (if it exists) is the vector $V \in \mathcal{U}$ with the property that $X-V$ is perpendicular to \mathcal{U} :

$$\langle X-V, U \rangle = 0, \quad U \in \mathcal{U} \quad (4.11.29)$$

The projection has two critical properties: It is unique (if it exists) and it is the vector in \mathcal{U} closest to X . If you look at the proofs of these results, you will see that they are essentially the same as the ones used for the best predictors of X mentioned at the beginning of this subsection. Moreover, the proofs use only vector space concepts—the fact that our vectors are random variables on a probability space plays no special role.

The projection of X onto \mathcal{U} (if it exists) is unique.

Proof

Suppose that V_1 and V_2 satisfy the definition. then

$$\|V_1 - V_2\|_2^2 = \langle V_1 - V_2, V_1 - V_2 \rangle = \langle V_1 - X + X - V_2, V_1 - V_2 \rangle = \langle V_1 - X, V_1 - V_2 \rangle + \langle X - V_2, V_1 - V_2 \rangle = 0 \quad (4.11.30)$$

Hence $V_1 \equiv V_2$. The last equality in the displayed equation holds by assumption and the fact that $V_1 - V_2 \in \mathcal{U}$

Suppose that V is the projection of X onto \mathcal{U} . Then

1. $\|X - V\|_2^2 \leq \|X - U\|_2^2$ for all $U \in \mathcal{U}$.
2. Equality holds in (a) if and only if $U \equiv V$

Proof

1. If $U \in \mathcal{U}$ then

$$\|X - U\|_2^2 = \|X - V + V - U\|_2^2 = \|X - V\|_2^2 + 2\langle X - V, V - U \rangle + \|V - U\|_2^2 \quad (4.11.31)$$

But the middle terms is 0 so

$$\|X - U\|_2^2 = \|X - V\|_2^2 + \|V - U\|_2^2 \geq \|X - V\|_2^2 \quad (4.11.32)$$

2. Equality holds if and only if $\|V - U\|_2^2 = 0$, if and only if $V \equiv U$.

Now let's return to our study of best predictors of a random variable.

If $X \in \mathcal{L}_2$ then the set $\mathcal{W}_X = \{a + bX : a \in \mathbb{R}, b \in \mathbb{R}\}$ is a subspace of \mathcal{L}_2 . In fact, it is the subspace *generated* by X and 1.

Proof

Note that \mathcal{W}_X is the set of all *linear combinations* of the vectors 1 and X . If $U, V \in \mathcal{W}_X$ then $U + V \in \mathcal{W}_X$. If $U \in \mathcal{W}_X$ and $c \in \mathbb{R}$ then $cU \in \mathcal{W}_X$.

Recall that for $X, Y \in \mathcal{L}_2$, the best linear predictor of Y based on X is

$$L(Y | X) = \mathbb{E}(Y) + \frac{\text{cov}(X, Y)}{\text{var}(X)} [X - \mathbb{E}(X)] \quad (4.11.33)$$

Here is the meaning of the predictor in the context of our vector spaces.

If $X, Y \in \mathcal{L}_2$ then $L(Y | X)$ is the projection of Y onto \mathcal{W}_X .

Proof

Note first that $L(Y | X) \in \mathcal{W}_X$. Thus, we just need to show that $Y - L(Y | X)$ is perpendicular to \mathcal{W}_X . For this, it suffices to show

1. $\langle Y - L(Y | X), X \rangle = 0$
2. $\langle Y - L(Y | X), 1 \rangle = 0$

We have already done this in the earlier sections, but for completeness, we do it again. Note that $\mathbb{E}(X[X - \mathbb{E}(X)]) = \text{var}(X)$. Hence $\mathbb{E}[XL(Y | X)] = \mathbb{E}(X)\mathbb{E}(Y) + \text{cov}(X, Y) = \mathbb{E}(XY)$. This gives (a). By linearity, $\mathbb{E}[L(Y | X)] = \mathbb{E}(Y)$ so (b) holds as well.

The previous result is actually just the random variable version of the standard formula for the projection of a vector onto a space spanned by two other vectors. Note that 1 is a unit vector and that $X_0 = X - \mathbb{E}(X) = X - \langle X, 1 \rangle 1$ is perpendicular to 1. Thus, $L(Y | X)$ is just the sum of the projections of Y onto 1 and X_0 :

$$L(Y | X) = \langle Y, 1 \rangle 1 + \frac{\langle Y, X_0 \rangle}{\langle X_0, X_0 \rangle} X_0 \quad (4.11.34)$$

Suppose now that \mathcal{G} is a sub σ -algebra of \mathcal{F} . Of course if $X : \Omega \rightarrow \mathbb{R}$ is \mathcal{G} -measurable then X is \mathcal{F} -measurable, so $\mathcal{L}_2(\mathcal{G})$ is a subspace of $\mathcal{L}_2(\mathcal{F})$.

If $X \in \mathcal{L}_2(\mathcal{F})$ then $\mathbb{E}(X | \mathcal{G})$ is the projection of X onto $\mathcal{L}_2(\mathcal{G})$.

Proof

This is essentially the definition of $\mathbb{E}(X | \mathcal{G})$ as the only (up to equivalence) random variable in $\mathcal{L}_2(\mathcal{G})$ with $\mathbb{E}[\mathbb{E}(X | \mathcal{G})U] = \mathbb{E}(XU)$ for every $U \in \mathcal{L}_2(\mathcal{G})$.

But remember that $\mathbb{E}(X | \mathcal{G})$ is defined more generally for $X \in \mathcal{L}_1(\mathcal{F})$. Our final result in this discussion concerns convergence.

Suppose that $k \in [1, \infty)$ and that \mathcal{G} is a sub σ -algebra of \mathcal{F} .

1. If $X \in \mathcal{L}_k(\mathcal{F})$ then $\mathbb{E}(X | \mathcal{G}) \in \mathcal{L}_k(\mathcal{G})$
2. If $X_n \in \mathcal{L}_k(\mathcal{F})$ for $n \in \mathbb{N}_+$, $X \in \mathcal{L}_k(\mathcal{F})$, and $X_n \rightarrow X$ as $n \rightarrow \infty$ in $\mathcal{L}_k(\mathcal{F})$ then $\mathbb{E}(X_n | \mathcal{G}) \rightarrow \mathbb{E}(X | \mathcal{G})$ as $n \rightarrow \infty$ in $\mathcal{L}_k(\mathcal{G})$

Proof

1. Note that $|\mathbb{E}(X | \mathcal{G})| \leq \mathbb{E}(|X| | \mathcal{G})$. Since $t \mapsto t^k$ is increasing and convex on $[0, \infty)$ we have

$$|\mathbb{E}(X | \mathcal{G})|^k \leq [\mathbb{E}(|X| | \mathcal{G})]^k \leq \mathbb{E}(|X|^k | \mathcal{G}) \quad (4.11.35)$$

The last step uses Jensen's inequality. Taking expected values gives

$$\mathbb{E}[|\mathbb{E}(X | \mathcal{G})|^k] \leq \mathbb{E}(|X|^k) < \infty \quad (4.11.36)$$

2. Using the same ideas,

$$\mathbb{E} \left[|\mathbb{E}(X_n | \mathcal{G}) - \mathbb{E}(X | \mathcal{G})|^k \right] = \mathbb{E} \left[|\mathbb{E}(X_n - X | \mathcal{G})|^k \right] \leq \mathbb{E}[|X_n - X|^k] \quad (4.11.37)$$

By assumption, the right side converges to 0 as $n \rightarrow \infty$ and hence so does the left side.

Examples and Applications

App Exercises

In the error function app, select the root mean square error function. Click on the x -axis to generate an empirical distribution, and note the shape and location of the graph of the error function.

In the error function app, select the mean absolute error function. Click on the x -axis to generate an empirical distribution, and note the shape and location of the graph of the error function.

Computational Exercises

Suppose that X is uniformly distributed on the interval $[0, 1]$.

1. Find $\|X\|_k$ for $k \in [1, \infty)$.
2. Graph $\|X\|_k$ as a function of $k \in [1, \infty)$.
3. Find $\lim_{k \rightarrow \infty} \|X\|_k$.

Answer

1. $\frac{1}{(k+1)^{1/k}}$
3. 1

Suppose that X has probability density function $f(x) = \frac{a}{x^{a+1}}$ for $1 \leq x < \infty$, where $a > 0$ is a parameter. Thus, X has the Pareto distribution with shape parameter a .

1. Find $\|X\|_k$ for $k \in [1, \infty)$.
2. Graph $\|X\|_k$ as a function of $k \in (1, a)$.
3. Find $\lim_{k \uparrow a} \|X\|_k$.

Answer

1. $\left(\frac{a}{a-k}\right)^{1/k}$ if $k < a$, ∞ if $k \geq a$
3. ∞

Suppose that (X, Y) has probability density function $f(x, y) = x + y$ for $0 \leq x \leq 1$, $0 \leq y \leq 1$. Verify Minkowski's inequality.

Answer

1. $\|X + Y\|_k = \left(\frac{2^{k+2}-2}{(k+2)(k+3)}\right)^{1/k}$
2. $\|X\|_k + \|Y\|_k = 2\left(\frac{1}{k+2} + \frac{1}{2(k+1)}\right)^{1/k}$

Let X be an indicator random variable with $\mathbb{P}(X = 1) = p$, where $0 \leq p \leq 1$. Graph $\mathbb{E}(|X - t|)$ as a function of $t \in \mathbb{R}$ in each of the cases below. In each case, find the minimum value of the function and the values of t where the minimum occurs.

1. $p < \frac{1}{2}$
2. $p = \frac{1}{2}$
3. $p > \frac{1}{2}$

Answer

1. The minimum is p and occurs at $t = 0$.
2. The minimum is $\frac{1}{2}$ and occurs for $t \in [0, 1]$
3. The minimum is $1 - p$ and occurs at $t = 1$

Suppose that X is uniformly distributed on the interval $[0, 1]$. Find $d_1(X, t) = \mathbb{E}(|X - t|)$ as a function of t and sketch the graph. Find the minimum value of the function and the value of t where the minimum occurs.

Suppose that X is uniformly distributed on the set $[0, 1] \cup [2, 3]$. Find $d_1(X, t) = \mathbb{E}(|X - t|)$ as a function of t and sketch the graph. Find the minimum value of the function and the values of t where the minimum occurs.

Suppose that (X, Y) has probability density function $f(x, y) = x + y$ for $0 \leq x \leq 1$, $0 \leq y \leq 1$. Verify Hölder's inequality in the following cases:

1. $j = k = 2$
2. $j = 3, k = \frac{3}{2}$

Answer

1. $\|X\|_2 \|Y\|_2 = \frac{5}{12}$
2. $\|X\|_3 + \|Y\|_{3/2} \approx 0.4248$

Counterexamples

The following exercise shows that convergence with probability 1 does not imply convergence in mean.

Suppose that (X_1, X_2, \dots) is a sequence of independent random variables with

$$\mathbb{P}(X = n^3) = \frac{1}{n^2}, \quad \mathbb{P}(X_n = 0) = 1 - \frac{1}{n^2}; \quad n \in \mathbb{N}_+ \quad (4.11.38)$$

1. $X_n \rightarrow 0$ as $n \rightarrow \infty$ with probability 1.
2. $X_n \rightarrow 0$ as $n \rightarrow \infty$ in probability.
3. $\mathbb{E}(X_n) \rightarrow \infty$ as $n \rightarrow \infty$.

Proof

1. This follows from the basic characterization of convergence with probability 1: $\sum_{n=1}^{\infty} \mathbb{P}(X_n > \epsilon) = \sum_{n=1}^{\infty} 1/n^2 < \infty$ for $0 < \epsilon < 1$.
2. This follows since convergence with probability 1 implies convergence in probability.
3. Note that $\mathbb{E}(X_n) = n^3/n^2 = n$ for $n \in \mathbb{N}_+$.

The following exercise shows that convergence in mean does not imply convergence with probability 1.

Suppose that (X_1, X_2, \dots) is a sequence of independent indicator random variables with

$$\mathbb{P}(X_n = 1) = \frac{1}{n}, \quad \mathbb{P}(X_n = 0) = 1 - \frac{1}{n}; \quad n \in \mathbb{N}_+ \quad (4.11.39)$$

1. $\mathbb{P}(X_n = 0 \text{ for infinitely many } n) = 1$.
2. $\mathbb{P}(X_n = 1 \text{ for infinitely many } n) = 1$.
3. $\mathbb{P}(X_n \text{ does not converge as } n \rightarrow \infty) = 1$.
4. $X_n \rightarrow 0$ as $n \rightarrow \infty$ in k th mean for every $k \geq 1$.

Proof

1. This follows from the second Borel-Cantelli lemma since $\sum_{n=1}^{\infty} \mathbb{P}(X_n = 1) = \sum_{n=1}^{\infty} 1/n = \infty$.
2. This also follows from the second Borel-Cantelli lemma since $\sum_{n=1}^{\infty} \mathbb{P}(X_n = 0) = \sum_{n=1}^{\infty} (1 - 1/n) = \infty$.
3. This follows from parts (a) and (b).
4. Note that $\mathbb{E}(X_n) = 1/n \rightarrow 0$ as $n \rightarrow \infty$.

The following exercise show that convergence of the k th means does not imply convergence *in* k th mean.

Suppose that U has the Bernoulli distribution with parameter $\frac{1}{2}$, so that $\mathbb{P}(U = 1) = \mathbb{P}(U = 0) = \frac{1}{2}$. Let $X_n = U$ for $n \in \mathbb{N}_+$ and let $X = 1 - U$. Let $k \in [1, \infty)$. Then

1. $\mathbb{E}(X_n^k) = \mathbb{E}(X^k) = \frac{1}{2}$ for $n \in \mathbb{N}_+$, so $\mathbb{E}(X_n^k) \rightarrow \mathbb{E}(X^k)$ as $n \rightarrow \infty$
2. $\mathbb{E}(|X_n - X|^k) = 1$ for $n \in \mathbb{N}$ so X_n does not converge to X as $n \rightarrow \infty$ in \mathcal{L}_k .

Proof

1. Note that $X_n^k = U^k = U$ for $n \in \mathbb{N}_+$, since U just takes values 0 and 1. Also, U and $1 - U$ have the same distribution so $\mathbb{E}(U) = \mathbb{E}(1 - U) = \frac{1}{2}$.
2. Note that $X_n - X = U - (1 - U) = 2U - 1$ for $n \in \mathbb{N}_+$. Again, U just takes values 0 and 1, so $|2U - 1| = 1$.

This page titled [4.11: Vector Spaces of Random Variables](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

4.12: Uniformly Integrable Variables

Two of the most important modes of convergence in probability theory are convergence with probability 1 and convergence in mean. As we have noted several times, neither mode of convergence implies the other. However, if we impose an additional condition on the sequence of variables, convergence with probability 1 will imply convergence in mean. The purpose of this brief, but advanced section, is to explore the additional condition that is needed. This section is particularly important for the theory of martingales.

Basic Theory

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. So Ω is the set of outcomes, \mathcal{F} is the σ -algebra of events, and \mathbb{P} is the probability measure on the sample space (Ω, \mathcal{F}) . In this section, all random variables that are mentioned are assumed to be real valued, unless otherwise noted. Next, recall from the section on vector spaces that for $k \in [1, \infty)$, \mathcal{L}_k is the vector space of random variables X with $\mathbb{E}(|X|^k) < \infty$, endowed with the norm $\|X\|_k = [\mathbb{E}(X^k)]^{1/k}$. In particular, $X \in \mathcal{L}_1$ simply means that $\mathbb{E}(|X|) < \infty$ so that $\mathbb{E}(X)$ exists as a real number. From the section on expected value as an integral, recall the following notation, assuming of course that the expected value makes sense:

$$\mathbb{E}(X; A) = \mathbb{E}(X\mathbf{1}_A) = \int_A X d\mathbb{P} \quad (4.12.1)$$

Definition

The following result is motivation for the main definition in this section.

If X is a random variable then $\mathbb{E}(|X|) < \infty$ if and only if $\mathbb{E}(|X|; |X| \geq x) \rightarrow 0$ as $x \rightarrow \infty$.

Proof

Note that that $|X|\mathbf{1}(|X| \leq x)$ is nonnegative, increasing in $x \in [0, \infty)$ and $|X|\mathbf{1}(|X| \leq x) \rightarrow |X|$ as $x \rightarrow \infty$. From the monotone convergence theorem, $\mathbb{E}(|X|; |X| \leq x) \rightarrow \mathbb{E}(|X|)$ as $x \rightarrow \infty$. On the other hand,

$$\mathbb{E}(|X|) = \mathbb{E}(|X|; |X| \leq x) + \mathbb{E}(|X|; |X| > x) \quad (4.12.2)$$

If $\mathbb{E}(|X|) < \infty$ then taking limits in the displayed equation shows that $\mathbb{E}(|X|; |X| > x) \rightarrow 0$ as $x \rightarrow \infty$. On the other hand, $\mathbb{E}(|X|; |X| \leq x) \leq x$. So if $\mathbb{E}(|X|) = \infty$ then $\mathbb{E}(|X|; |X| > x) = \infty$ for every $x \in [0, \infty)$.

Suppose now that X_i is a random variable for each i in a nonempty index set I (not necessarily countable). The critical definition for this section is to require the convergence in the previous theorem to hold *uniformly* for the collection of random variables $\mathbf{X} = \{X_i : i \in I\}$.

The collection $\mathbf{X} = \{X_i : i \in I\}$ is *uniformly integrable* if for each $\epsilon > 0$ there exists $x > 0$ such that for all $i \in I$,

$$\mathbb{E}(|X_i|; |X_i| > x) < \epsilon \quad (4.12.3)$$

Equivalently $\mathbb{E}(|X_i|; |X_i| > x) \rightarrow 0$ as $x \rightarrow \infty$ uniformly in $i \in I$.

Properties

Our next discussion centers on conditions that ensure that the collection of random variables $\mathbf{X} = \{X_i : i \in I\}$ is uniformly integrable. Here is an equivalent characterization:

The collection $\mathbf{X} = \{X_i : i \in I\}$ is uniformly integrable if and only if the following conditions hold:

1. $\{\mathbb{E}(|X_i|) : i \in I\}$ is bounded.
2. For each $\epsilon > 0$ there exists $\delta > 0$ such that if $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta$ then $\mathbb{E}(|X_i|; A) < \epsilon$ for all $i \in I$.

Proof

Suppose that \mathbf{X} is uniformly integrable. With $\epsilon = 1$ there exists $x > 0$ such that $\mathbb{E}(|X_i|; |X_i| > x) < 1$ for all $i \in I$. Hence

$$\mathbb{E}(|X_i|) = \mathbb{E}(|X_i|; |X_i| \leq x) + \mathbb{E}(|X_i|; |X_i| > x) \leq x + 1, \quad i \in I \quad (4.12.4)$$

so (a) holds. For (b), let $\epsilon > 0$. There exists $x > 0$ such that $\mathbb{E}(|X_i|; |X_i| > x) < \epsilon/2$ for all $i \in I$. Let $\delta = \epsilon/2x$. If $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta$ then

$$\mathbb{E}(|X_i|; A) = \mathbb{E}(|X_i|; A \cap \{|X| \leq x\}) + \mathbb{E}(|X_i|; A \cap \{|X| > x\}) \leq x\mathbb{P}(A) + \mathbb{E}(|X_i|; |X| > x) < \epsilon/2 + \epsilon/2 = \epsilon \quad (4.12.5)$$

Conversely, suppose that (a) and (b) hold. By (a), there exists $c > 0$ such that $\mathbb{E}(|X_i|) \leq c$ for all $i \in I$. Let $\epsilon > 0$. By (b) there exists $\delta > 0$ such that if $A \in \mathcal{F}$ with $\mathbb{P}(A) < \delta$ then $\mathbb{E}(|X_i|; A) < \epsilon$ for all $i \in I$. Next, by Markov's inequality,

$$\mathbb{P}(|X_i| > x) \leq \frac{\mathbb{E}(|X_i|)}{x} \leq \frac{c}{x}, \quad i \in I \quad (4.12.6)$$

Pick $x > 0$ such that $c/x < \delta$, so that $\mathbb{P}(|X_i| > x) < \delta$ for each $i \in I$. Then for each $j \in I$, $\mathbb{E}(|X_i|; |X_j| > x) < \epsilon$ for all $i \in I$ and so in particular, $\mathbb{E}(|X_i|; |X_i| > x) < \epsilon$ for all $i \in I$. Hence \mathbf{X} is uniformly integrable.

Condition (a) means that \mathbf{X} is bounded (in norm) as a subset of the vector space \mathcal{L}_1 . Trivially, a *finite* collection of integrable random variables is uniformly integrable.

Suppose that I is finite and that $\mathbb{E}(|X_i|) < \infty$ for each $i \in I$. Then $\mathbf{X} = \{X_i : i \in I\}$ is uniformly integrable.

A subset of a uniformly integrable set of variables is also uniformly integrable.

If $\{X_i : i \in I\}$ is uniformly integrable and J is a nonempty subset of I , then $\{X_j : j \in J\}$ is uniformly integrable.

If the random variables in the collection are dominated in absolute value by a random variable with finite mean, then the collection is uniformly integrable.

Suppose that Y is a nonnegative random variable with $\mathbb{E}(Y) < \infty$ and that $|X_i| \leq Y$ for each $i \in I$. Then $\mathbf{X} = \{X_i : i \in I\}$ is uniformly integrable.

Proof

Clearly $\mathbb{E}(|X_i|; |X_i| > x) \leq \mathbb{E}(Y; Y > x)$ for $x \in [0, \infty)$ and for all $i \in I$. The right side is independent of $i \in I$, and by the [theorem above](#), converges to 0 as $x \rightarrow \infty$. Hence \mathbf{X} is uniformly integrable.

The following result is more general, but essentially the same proof works.

Suppose that $\mathbf{Y} = \{Y_j : j \in J\}$ is uniformly integrable, and $\mathbf{X} = \{X_i : i \in I\}$ is a set of variables with the property that for each $i \in I$ there exists $j \in J$ such that $|X_i| \leq |Y_j|$. Then \mathbf{X} is uniformly integrable.

As a simple corollary, if the variables are bounded in absolute value then the collection is uniformly integrable.

If there exists $c > 0$ such that $|X_i| \leq c$ for all $i \in I$ then $\mathbf{X} = \{X_i : i \in I\}$ is uniformly integrable.

Just having $\mathbb{E}(|X_i|)$ bounded in $i \in I$ (condition (a) in the [characterization above](#)) is not sufficient for $\mathbf{X} = \{X_i : i \in I\}$ to be uniformly integrable; a [counterexample](#) is given below. However, if $\mathbb{E}(|X_i|^k)$ is bounded in $i \in I$ for some $k > 1$, then \mathbf{X} is uniformly integrable. This condition means that \mathbf{X} is bounded (in norm) as a subset of the vector space \mathcal{L}_k .

If $\{\mathbb{E}(|X_i|^k) : i \in I\}$ is bounded for some $k > 1$, then $\{X_i : i \in I\}$ is uniformly integrable.

Proof

Suppose that for some $k > 1$ and $c > 0$, $\mathbb{E}(|X_i|^k) \leq c$ for all $i \in I$. Then $k - 1 > 0$ and so $t \mapsto t^{k-1}$ is increasing on $(0, \infty)$. So if $|X_i| > x$ for $x > 0$ then

$$|X_i|^k = |X_i| |X_i|^{k-1} \geq |X_i| x^{k-1} \quad (4.12.7)$$

Hence $|X_i| \leq |X_i|^k / x^{k-1}$ on the event $|X_i| > x$. Therefore

$$\mathbb{E}(|X_i|; |X_i| > x) \leq \mathbb{E}\left(\frac{|X_i|^k}{x^{k-1}}; |X_i| > x\right) \leq \frac{\mathbb{E}(|X_i|^k)}{x^{k-1}} \leq \frac{c}{x^{k-1}} \quad (4.12.8)$$

The last expression is independent of $i \in I$ and converges to 0 as $x \rightarrow \infty$. Hence \mathbf{X} is uniformly integrable.

Uniformly integrability is closed under the operations of addition and scalar multiplication.

Suppose that $\mathbf{X} = \{X_i : i \in I\}$ and $\mathbf{Y} = \{Y_i : i \in I\}$ are uniformly integrable and that $c \in \mathbb{R}$. Then each of the following collections is also uniformly integrable.

1. $\mathbf{X} + \mathbf{Y} = \{X_i + Y_i : i \in I\}$
2. $c\mathbf{X} = \{cX_i : i \in I\}$

Proof

We use the [characterization above](#). The proofs use standard techniques, so try them yourself.

1. There exists $a, b \in (0, \infty)$ such that $\mathbb{E}(|X_i|) \leq a$ and $\mathbb{E}(|Y_i|) \leq b$ for all $i \in I$. Hence

$$\mathbb{E}(|X_i + Y_i|) \leq \mathbb{E}(|X_i| + |Y_i|) \leq \mathbb{E}(|X_i|) + \mathbb{E}(|Y_i|) \leq a + b, \quad i \in I \quad (4.12.9)$$

Next let $\epsilon > 0$. There exists $\delta_1 > 0$ such that if $A \in \mathcal{F}$ with $\mathbb{P}(A) < \delta_1$ then $\mathbb{E}(|X_i|; A) < \epsilon/2$ for all $i \in I$, and similarly, there exists $\delta_2 > 0$ such that if $A \in \mathcal{F}$ with $\mathbb{P}(A) < \delta_2$ then $\mathbb{E}(|Y_i|; A) < \epsilon/2$ for all $i \in I$. Hence if $A \in \mathcal{F}$ with $\mathbb{P}(A) < \delta_1 \wedge \delta_2$ then

$$\mathbb{E}(|X_i + Y_i|; A) \leq \mathbb{E}(|X_i| + |Y_i|; A) = \mathbb{E}(|X_i|; A) + \mathbb{E}(|Y_i|; A) < \epsilon/2 + \epsilon/2 = \epsilon, \quad i \in I \quad (4.12.10)$$

2. There exists $a \in (0, \infty)$ such that $\mathbb{E}(|X_i|) \leq a$ for all $i \in I$. Hence

$$\mathbb{E}(|cX_i|) = |c|\mathbb{E}(|X_i|) \leq ca, \quad i \in I \quad (4.12.11)$$

The second condition is trivial if $c = 0$, so suppose $c \neq 0$. For $\epsilon > 0$ there exists $\delta > 0$ such that if $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta$ then $\mathbb{E}(|X_i|; A) < \epsilon/c$ for all $i \in I$. Hence $\mathbb{E}(|cX_i|; A) = |c|\mathbb{E}(|X_i|; A) < \epsilon$.

The following corollary is trivial, but will be needed in our discussion of convergence below.

Suppose that $\{X_i : i \in I\}$ is uniformly integrable and that X is a random variable with $\mathbb{E}(|X|) < \infty$. Then $\{X_i - X : i \in I\}$ is uniformly integrable.

Proof

Let $Y_i = X$ for each $i \in I$. Then $\{Y_i : i \in I\}$ is uniformly integrable, so the result follows from the previous theorem.

Convergence

We now come to the main results, and the reason for the definition of uniform integrability in the first place. To set up the notation, suppose that X_n is a random variable for $n \in \mathbb{N}_+$ and that X is a random variable. We know that if $X_n \rightarrow X$ as $n \rightarrow \infty$ in mean then $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability. The converse is also true if and only if the sequence is uniformly integrable. Here is the first half:

If $X_n \rightarrow X$ as $n \rightarrow \infty$ in mean, then $\{X_n : n \in \mathbb{N}\}$ is uniformly integrable.

Proof

The hypothesis means that $X_n \rightarrow X$ as $n \rightarrow \infty$ in the vector space \mathcal{L}_1 . That is, $\mathbb{E}(|X_n|) < \infty$ for $n \in \mathbb{N}_+$, $\mathbb{E}(|X|) < \infty$, and $\mathbb{E}(|X_n - X|) \rightarrow 0$ as $n \rightarrow \infty$. From the last section, we know that this implies that $\mathbb{E}(|X_n|) \rightarrow \mathbb{E}(|X|)$ as $n \rightarrow \infty$, so $\mathbb{E}(|X_n|)$ is bounded in $n \in \mathbb{N}$. Let $\epsilon > 0$. Then there exists $N \in \mathbb{N}_+$ such that if $n > N$ then $\mathbb{E}(|X_n - X|) < \epsilon/2$. Since all of our variables are in \mathcal{L}_1 , for each $n \in \mathbb{N}_+$ there exists $\delta_n > 0$ such that if $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta_n$ then $\mathbb{E}(|X_n - X|; A) < \epsilon/2$. Similarly, there exists $\delta_0 > 0$ such that if $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta_0$ then $\mathbb{E}(|X|; A) < \epsilon/2$. Let $\delta = \min\{\delta_n : n \in \{0, 1, \dots, N\}\}$ so $\delta > 0$. If $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta$ then

$$\mathbb{E}(|X_n|; A) = \mathbb{E}(|X_n - X + X|; A) \leq \mathbb{E}(|X_n - X|; A) + \mathbb{E}(|X|; A), \quad n \in \mathbb{N}_+ \quad (4.12.12)$$

If $n \leq N$ then $\mathbb{E}(|X_n - X|; A) \leq \epsilon/2$ since $\delta \leq \delta_n$. If $n > N$ then $\mathbb{E}(|X_n - X|; A) \leq \mathbb{E}(|X_n - X|) < \epsilon/2$. For all n , $\mathbb{E}(|X|; A) < \epsilon/2$ since $\delta \leq \delta_0$. So for all $n \in \mathbb{N}_+$, $\mathbb{E}(|X_n|; A) < \epsilon$ and hence $\{X_n : n \in \mathbb{N}_+\}$ is uniformly integrable.

Here is the more important half, known as the *uniform integrability theorem*:

If $\{X_n : n \in \mathbb{N}_+\}$ is uniformly integrable and $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability, then $X_n \rightarrow X$ as $n \rightarrow \infty$ in mean.

Proof

Since $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability, we know that there exists a subsequence $(X_{n_k} : k \in \mathbb{N}_+)$ of $(X_n : n \in \mathbb{N}_+)$ such that $X_{n_k} \rightarrow X$ as $k \rightarrow \infty$ with probability 1. By the uniform integrability, $\mathbb{E}(|X_n|)$ is bounded in $n \in \mathbb{N}_+$. Hence by Fatou's lemma

$$\mathbb{E}(|X|) = \mathbb{E}\left(\liminf_{k \rightarrow \infty} |X_{n_k}|\right) \leq \liminf_{n \rightarrow \infty} \mathbb{E}(|X_n|) \leq \limsup_{n \rightarrow \infty} \mathbb{E}(|X_n|) < \infty \quad (4.12.13)$$

Let $Y_n = X_n - X$ for $n \in \mathbb{N}_+$. From the [corollary above](#), we know that $\{Y_n : n \in \mathbb{N}_+\}$ is uniformly integrable, and we also know that Y_n converges to 0 as $n \rightarrow \infty$ in probability. Hence we need to show that $Y_n \rightarrow 0$ as $n \rightarrow \infty$ in mean. Let $\epsilon > 0$. By uniform

integrability, there exists $\delta > 0$ such that if $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta$ then $\mathbb{E}(|Y_n| : A) < \epsilon/2$ for all $n \in \mathbb{N}$. Since $Y_n \rightarrow 0$ as $n \rightarrow \infty$ in probability, there exists $N \in \mathbb{N}_+$ such that if $n > N$ then $\mathbb{P}(|Y_n| > \epsilon/2) < \delta$. Hence if $n > N$ then

$$\mathbb{E}(|Y_n|) = \mathbb{E}(|Y_n|; |Y_n| \leq \epsilon/2) + \mathbb{E}(|Y_n|; |Y_n| > \epsilon/2) < \epsilon/2 + \epsilon/2 = \epsilon \quad (4.12.14)$$

Hence $Y_n \rightarrow 0$ as $n \rightarrow \infty$ in mean.

As a corollary, recall that if $X_n \rightarrow X$ as $n \rightarrow \infty$ with probability 1, then $X_n \rightarrow X$ as $n \rightarrow \infty$ in probability. Hence if $\mathbf{X} = \{X_n : n \in \mathbb{N}_+\}$ is uniformly integrable then $X_n \rightarrow X$ as $n \rightarrow \infty$ in mean.

Examples

Our first example shows that bounded \mathcal{L}_1 norm is not sufficient for uniform integrability.

Suppose that U is uniformly distributed on the interval $(0, 1)$ (so U has the *standard uniform distribution*). For $n \in \mathbb{N}_+$, let $X_n = n\mathbf{1}(U \leq 1/n)$. Then

1. $\mathbb{E}(|X_n|) = 1$ for all $n \in \mathbb{N}_+$
2. $\mathbb{E}(|X_n|; |X_n| > x) = 1$ for $x > 0$, $n \in \mathbb{N}_+$ with $n > x$

Proof

First note that $|X_n| = X_n$ since $X_n \geq 0$.

1. By definition, $\mathbb{E}(X_n) = n\mathbb{P}(U \leq 1/n) = n/n = 1$ for $n \in \mathbb{N}_+$.
2. If $n > x > 0$ then $X_n > x$ if and only if $X_n = n$ if and only if $U \leq 1/n$. Hence $\mathbb{E}(X_n; X_n > x) = n\mathbb{P}(U \leq 1/n) = 1$ as before.

By part (b), $\mathbb{E}(|X_n|; |X_n| > x)$ does not converge to 0 as $x \rightarrow \infty$ uniformly in $n \in \mathbb{N}_+$, so $\mathbf{X} = \{X_n : n \in \mathbb{N}_+\}$ is not uniformly integrable.

The next example gives an important application to conditional expected value. Recall that if X is a random variable with $\mathbb{E}(|X|) < \infty$ and \mathcal{G} is a sub σ -algebra of \mathcal{F} then $\mathbb{E}(X | \mathcal{G})$ is the expected value of X given the information in \mathcal{G} , and is the \mathcal{G} -measurable random variable closest to X in a sense. Indeed if $X \in \mathcal{L}_2(\mathcal{F})$ then $\mathbb{E}(X | \mathcal{G})$ is the projection of X onto $\mathcal{L}_2(\mathcal{G})$. The collection of all conditional expected values of X is uniformly integrable:

Suppose that X is a real-valued random variable with $\mathbb{E}(|X|) < \infty$. Then $\{\mathbb{E}(X | \mathcal{G}) : \mathcal{G} \text{ is a sub } \sigma\text{-algebra of } \mathcal{F}\}$ is uniformly integrable.

Proof

We use the [characterization above](#). Let \mathcal{G} be a sub σ -algebra of \mathcal{F} . Recall that $|\mathbb{E}(X | \mathcal{G})| \leq \mathbb{E}(|X| | \mathcal{G})$ and hence

$$\mathbb{E}[|\mathbb{E}(X | \mathcal{G})|] \leq \mathbb{E}[\mathbb{E}(|X| | \mathcal{G})] = \mathbb{E}(|X|) \quad (4.12.15)$$

So property (a) holds. Next let $\epsilon > 0$. Since $\mathbb{E}(|X|) < \infty$, there exists $\delta > 0$ such that if $A \in \mathcal{F}$ and $\mathbb{P}(A) < \delta$ then $\mathbb{E}(|X|; A) < \epsilon$. Suppose that $A \in \mathcal{G}$ with $\mathbb{P}(A) < \delta$. Then $|\mathbb{E}(X | \mathcal{G})|\mathbf{1}_A \leq \mathbb{E}(|X| | \mathcal{G})\mathbf{1}_A$ so

$$\mathbb{E}[|\mathbb{E}(X | \mathcal{G})|; A] \leq \mathbb{E}[\mathbb{E}(|X| | \mathcal{G}); A] = \mathbb{E}[\mathbb{E}(|X|\mathbf{1}_A | \mathcal{G})] = \mathbb{E}(|X|; A) < \epsilon \quad (4.12.16)$$

So condition (b) holds. Note that the first equality in the displayed equation holds since $A \in \mathcal{G}$.

Note that the collection of sub σ -algebras of \mathcal{F} , and so also the collection of conditional expected values above, might well be uncountable. The conditional expected values range from $\mathbb{E}(X)$, when $\mathcal{G} = \{\Omega, \emptyset\}$ to X itself, when $\mathcal{G} = \mathcal{F}$.

4.13: Kernels and Operators

The goal of this section is to study a type of mathematical object that arises naturally in the context of conditional expected value and parametric distributions, and is of fundamental importance in the study of stochastic processes, particularly Markov processes. In a sense, the main object of study in this section is a generalization of a matrix, and the operations generalizations of matrix operations. If you keep this in mind, this section may seem less abstract.

Basic Theory

Definitions

Recall that a measurable space (S, \mathcal{S}) consists of a set S and a σ -algebra \mathcal{S} of subsets of S . If μ is a positive measure on (S, \mathcal{S}) , then (S, \mathcal{S}, μ) is a measure space. The two most important special cases that we have studied frequently are

1. *Discrete*: S is countable, $\mathcal{S} = \mathcal{P}(S)$ is the collection of all subsets of S , and $\mu = \#$ is counting measure on (S, \mathcal{S}) .
2. *Euclidean*: S is a measurable subset of \mathbb{R}^n for some $n \in \mathbb{N}_+$, \mathcal{S} is the collection of subsets of S that are also measurable, and $\mu = \lambda_n$ is n -dimensional Lebesgue measure on (S, \mathcal{S}) .

More generally, S usually comes with a topology that is locally compact, Hausdorff, with a countable base (LCCB), and \mathcal{S} is the *Borel σ -algebra*, the σ -algebra generated by the topology (the collection of open subsets of S). The measure μ is usually a *Borel measure*, and so satisfies $\mu(C) < \infty$ if $C \subseteq S$ is compact. A discrete measure space is of this type, corresponding to the discrete topology. A Euclidean measure space is also of this type, corresponding to the Euclidean topology, if S is open or closed (which is usually the case). In the discrete case, every function from S to another measurable space is measurable, and every from function from S to another topological space is continuous, so the measure theory is not really necessary.

Recall also that the measure space (S, \mathcal{S}, μ) is σ -finite if there exists a countable collection $\{A_i : i \in I\} \subseteq \mathcal{S}$ such that $\mu(A_i) < \infty$ for $i \in I$ and $S = \bigcup_{i \in I} A_i$. If (S, \mathcal{S}, μ) is a Borel measure space corresponding to an LCCB topology, then it is σ -finite.

If $f : S \rightarrow \mathbb{R}$ is measurable, define $\|f\| = \sup\{|f(x)| : x \in S\}$. Of course we may well have $\|f\| = \infty$. Let $\mathcal{B}(S)$ denote the collection of bounded measurable functions $f : S \rightarrow \mathbb{R}$. Under the usual operations of pointwise addition and scalar multiplication, $\mathcal{B}(S)$ is a vector space, and $\|\cdot\|$ is the natural norm on this space, known as the *supremum norm*. This vector space plays an important role.

In this section, it is sometimes more natural to write integrals with respect to the positive measure μ with the differential *before* the integrand, rather than after. However, rest assured that this is mere notation, the meaning of the integral is the same. So if $f : S \rightarrow \mathbb{R}$ is measurable then we may write the integral of f with respect to μ in operator notation as

$$\mu f = \int_S \mu(dx) f(x) \quad (4.13.1)$$

assuming, as usual, that the integral exists. This will be the case if f is nonnegative, although ∞ is a possible value. More generally, the integral exists in $\mathbb{R} \cup \{-\infty, \infty\}$ if $\mu f^+ < \infty$ or $\mu f^- < \infty$ where f^+ and f^- are the positive and negative parts of f . If both are finite, the integral exists in \mathbb{R} (and f is *integrable* with respect to μ). If μ is a probability measure and we think of (S, \mathcal{S}) as the sample space of a random experiment, then we can think of f as a real-valued random variable, in which case our new notation is not too far from our traditional expected value $\mathbb{E}(f)$. Our main definition comes next.

Suppose that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces. A *kernel* from (S, \mathcal{S}) to (T, \mathcal{T}) is a function $K : S \times \mathcal{T} \rightarrow [0, \infty]$ such that

1. $x \mapsto K(x, A)$ is a measurable function from S into $[0, \infty]$ for each $A \in \mathcal{T}$.
2. $A \mapsto K(x, A)$ is a positive measure on \mathcal{T} for each $x \in S$.

If $(T, \mathcal{T}) = (S, \mathcal{S})$, then K is said to be a *kernel on* (S, \mathcal{S}) .

There are several classes of kernels that deserve special names.

Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) . Then

1. K is σ -finite if the measure $K(x, \cdot)$ is σ -finite for every $x \in S$.
2. K is finite if $K(x, T) < \infty$ for every $x \in S$.
3. K is bounded if $K(x, T)$ is bounded in $x \in S$.
4. K is a probability kernel if $K(x, T) = 1$ for every $x \in S$.

Define $\|K\| = \sup\{K(x, T) : x \in S\}$, so that $\|K\| < \infty$ if K is a bounded kernel and $\|K\| = 1$ if K is a probability kernel.

So a probability kernel is bounded, a bounded kernel is finite, and a finite kernel is σ -finite. The terms *stochastic kernel* and *Markov kernel* are also used for probability kernels, and for a probability kernel $\|K\| = 1$ of course. The terms are consistent with terms used for measures: K is a finite kernel if and only if $K(x, \cdot)$ is a finite measure for each $x \in S$, and K is a probability kernel if and only if $K(x, \cdot)$ is a probability measure for each $x \in S$. Note that $\|K\|$ is simply the supremum norm of the function $x \mapsto K(x, T)$.

A kernel defines two natural integral operators, by operating on the *left* with measures, and by operating on the *right* with functions. As usual, we are often a bit casual with the question of existence. Basically in this section, we assume that any integrals mentioned exist.

Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) .

1. If μ is a positive measure on (S, \mathcal{S}) , then μK defined as follows is a positive measure on (T, \mathcal{T}) :

$$\mu K(A) = \int_S \mu(dx) K(x, A), \quad A \in \mathcal{T} \quad (4.13.2)$$

2. If $f : T \rightarrow \mathbb{R}$ is measurable, then $Kf : S \rightarrow \mathbb{R}$ defined as follows is measurable (assuming that the integrals exist in \mathbb{R}):

$$Kf(x) = \int_T K(x, dy) f(y), \quad x \in S \quad (4.13.3)$$

Proof

1. Clearly $\mu K(A) \geq 0$ for $A \in \mathcal{T}$. Suppose that $\{A_j : j \in J\}$ is a countable collection of disjoint sets in \mathcal{T} and $A = \bigcup_{j \in J} A_j$. Then

$$\begin{aligned} \mu K(A) &= \int_S \mu(dx) K(x, A) = \int_S \mu(dx) \left(\sum_{j \in J} K(x, A_j) \right) \\ &= \sum_{j \in J} \int_S \mu(dx) K(x, A_j) = \sum_{j \in J} \mu K(A_j) \end{aligned}$$

The interchange of sum and integral is justified since the terms are nonnegative.

2. The measurability of Kf follows from the measurability of f and of $x \mapsto K(x, A)$ for $A \in \mathcal{T}$, and from basic properties of the integral.

Thus, a kernel transforms measures on (S, \mathcal{S}) into measures on (T, \mathcal{T}) , and transforms certain measurable functions from T to \mathbb{R} into measurable functions from S to \mathbb{R} . Again, part (b) assumes that f is integrable with respect to the measure $K(x, \cdot)$ for every $x \in S$. In particular, the last statement will hold in the following important special case:

Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) and that $f \in \mathcal{B}(T)$.

1. If K is finite then Kf is defined and $\|Kf\| = \|K\| \|f\|$.
2. If K is bounded then $Kf \in \mathcal{B}(T)$.

Proof

1. If K is finite then

$$K|f|(x) = \int_T K(x, dy) |f(y)| \leq \int_T K(x, dy) \|f\| = \|f\| K(x, T) < \infty \quad x \in S \quad (4.13.4)$$

Hence f is integrable with respect to $K(x, \cdot)$ for each $x \in S$ so Kf is defined. Continuing with our inequalities, we have $|Kf(x)| \leq K|f|(x) \leq \|f\|K(x, T) \leq \|f\|\|K\|$ so $\|Kf\| \leq \|K\|\|f\|$. Moreover equality holds when $f = \mathbf{1}_T$, the constant function 1 on T .

2. If K is bounded then $\|K\| < \infty$ so from (a), $\|Kf\| < \infty$.

The *identity kernel* I on the measurable space (S, \mathcal{S}) is defined by $I(x, A) = \mathbf{1}(x \in A)$ for $x \in S$ and $A \in \mathcal{S}$.

Thus, $I(x, A) = 1$ if $x \in A$ and $I(x, A) = 0$ if $x \notin A$. So $x \mapsto I(x, A)$ is the *indicator function* of $A \in \mathcal{S}$, while $A \mapsto I(x, A)$ is *point mass* at $x \in S$. Clearly the identity kernel is a probability kernel. If we need to indicate the dependence on the particular space, we will add a subscript. The following result justifies the name.

Let I denote the identity kernel on (S, \mathcal{S}) .

1. If μ is a positive measure on (S, \mathcal{S}) then $\mu I = \mu$.
2. If $f : S \rightarrow \mathbb{R}$ is measurable, then $If = f$.

Constructions

We can create a new kernel from two given kernels, by the usual operations of addition and scalar multiplication.

Suppose that K and L are kernels from (S, \mathcal{S}) to (T, \mathcal{T}) , and that $c \in [0, \infty)$. Then cK and $K + L$ defined below are also kernels from (S, \mathcal{S}) to (T, \mathcal{T}) .

1. $(cK)(x, A) = cK(x, A)$ for $x \in S$ and $A \in \mathcal{T}$.
2. $(K + L)(x, A) = K(x, A) + L(x, A)$ for $x \in S$ and $A \in \mathcal{T}$.

If K and L are σ -finite (finite) (bounded) then cK and $K + L$ are σ -finite (finite) (bounded), respectively.

Proof

These results are simple.

1. Since $x \mapsto K(x, A)$ is measurable for $A \in \mathcal{T}$, so is $x \mapsto cK(x, A)$. Since $A \mapsto K(x, A)$ is a positive measure on (T, \mathcal{T}) for $x \in S$, so is $A \mapsto cK(x, A)$ since $c \geq 0$.
2. Since $x \mapsto K(x, A)$ and $x \mapsto L(x, A)$ are measurable for $A \in \mathcal{T}$, so is $x \mapsto K(x, A) + L(x, A)$. Since $A \mapsto K(x, A)$ and $A \mapsto L(x, A)$ are positive measures on (T, \mathcal{T}) for $x \in S$, so is $A \mapsto K(x, A) + L(x, A)$.

A simple corollary of the last result is that if $a, b \in [0, \infty)$ then $aK + bL$ is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) . In particular, if K, L are probability kernels and $p \in (0, 1)$ then $pK + (1 - p)L$ is a probability kernel. A more interesting and important way to form a new kernel from two given kernels is via a “multiplication” operation.

Suppose that K is a kernel from (R, \mathcal{R}) to (S, \mathcal{S}) and that L is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) . Then KL defined as follows is a kernel from (R, \mathcal{R}) to (T, \mathcal{T}) :

$$KL(x, A) = \int_S K(x, dy)L(y, A), \quad x \in R, A \in \mathcal{T} \quad (4.13.5)$$

1. If K is finite and L is bounded then KL is finite.
2. If K and L are bounded then KL is bounded.
3. If K and L are stochastic then KL is stochastic

Proof

The measurability of $x \mapsto (KL)(x, A)$ for $A \in \mathcal{T}$ follows from basic properties of the integral. For the second property, fix $x \in R$. Clearly $KL(x, A) \geq 0$ for $A \in \mathcal{T}$. Suppose that $\{A_j : j \in J\}$ is a countable collection of disjoint sets in \mathcal{T} and $A = \bigcup_{j \in J} A_j$. Then

$$\begin{aligned}
 KL(x, A) &= \int_S K(x, dy) L(x, A) = \int_S K(x, dy) \left(\sum_{j \in J} L(y, A_j) \right) \\
 &= \sum_{j \in J} \int_S K(x, dy) L(y, A_j) = \sum_{j \in J} KL(x, A_j)
 \end{aligned}$$

The interchange of sum and integral is justified since the terms are nonnegative.

Once again, the identity kernel lives up to its name:

Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) . Then

1. $I_S K = K$
2. $K I_T = K$

The next several results show that the operations are *associative* whenever they make sense.

Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) , μ is a positive measure on \mathcal{S} , $c \in [0, \infty)$, and $f : T \rightarrow \mathbb{R}$ is measurable. Then, assuming that the appropriate integrals exist,

1. $c(\mu K) = (c\mu)K$
2. $c(Kf) = (cK)f$
3. $(\mu K)f = \mu(Kf)$

Proof

These results follow easily from the definitions.

1. The common measure on \mathcal{T} is $c\mu K(A) = c \int_S \mu(dx) K(x, A)$ for $A \in \mathcal{T}$.
2. The common function from S to \mathbb{R} is $cKf(x) = c \int_S K(x, dy) f(y)$ for $x \in S$, assuming that the integral exists for $x \in S$.
3. The common real number is $\mu Kf = \int_S \mu(dx) \int_T K(x, dy) f(y)$, assuming that the integrals exist.

Suppose that K is a kernel from (R, \mathcal{R}) to (S, \mathcal{S}) and L is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) . Suppose also that μ is a positive measure on (R, \mathcal{R}) , $f : T \rightarrow \mathbb{R}$ is measurable, and $c \in [0, \infty)$. Then, assuming that the appropriate integrals exist,

1. $(\mu K)L = \mu(KL)$
2. $K(Lf) = (KL)f$
3. $c(KL) = (cK)L$

Proof

These results follow easily from the definitions.

1. The common measure on (T, \mathcal{T}) is $\mu KL(A) = \int_R \mu(dx) \int_S K(x, dy) L(y, A)$ for $A \in \mathcal{T}$.
2. The common measurable function from R to \mathbb{R} is $KLf(x) = \int_S K(x, dy) \int_T L(y, dz) f(z)$ for $x \in R$, assuming that the integral exists for $x \in S$.
3. The common kernel from (R, \mathcal{R}) to (T, \mathcal{T}) is $cKL(x, A) = c \int_S K(x, dy) L(y, A)$ for $x \in R$ and $A \in \mathcal{T}$.

Suppose that K is a kernel from (R, \mathcal{R}) to (S, \mathcal{S}) , L is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) , and M is a kernel from (T, \mathcal{T}) to (U, \mathcal{U}) . Then $(KL)M = K(LM)$.

Proof

This results follow easily from the definitions. The common kernel from (R, \mathcal{R}) to (U, \mathcal{U}) is

$$KLM(x, A) = \int_S K(x, dy) \int_T L(y, dz) M(z, A), \quad x \in R, A \in \mathcal{U} \quad (4.13.6)$$

The next several results show that the *distributive property* holds whenever the operations makes sense.

Suppose that K and L are kernels from (R, \mathcal{R}) to (S, \mathcal{S}) and that M and N are kernels from (S, \mathcal{S}) to (T, \mathcal{T}) . Suppose also that μ is a positive measure on (R, \mathcal{R}) and that $f : S \rightarrow \mathbb{R}$ is measurable. Then, assuming that the appropriate integrals exist,

1. $(K + L)M = KM + LM$
2. $K(M + N) = KM + KN$
3. $\mu(K + L) = \mu K + \mu L$
4. $(K + L)f = Kf + Lf$

Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) , and that μ and ν are positive measures on (S, \mathcal{S}) , and that f and g are measurable functions from T to \mathbb{R} . Then, assuming that the appropriate integrals exist,

1. $(\mu + \nu)K = \mu K + \nu K$
2. $K(f + g) = Kf + Kg$
3. $\mu(f + g) = \mu f + \mu g$
4. $(\mu + \nu)f = \mu f + \nu f$

In particular, note that if K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) , then the transformation $\mu \mapsto \mu K$ defined for positive measures on (S, \mathcal{S}) , and the transformation $f \mapsto Kf$ defined for measurable functions $f : T \rightarrow \mathbb{R}$ (for which Kf exists), are both *linear* operators. If μ is a positive measure on (S, \mathcal{S}) , then the integral operator $f \mapsto \mu f$ defined for measurable $f : S \rightarrow \mathbb{R}$ (for which μf exists) is also linear, but of course, we already knew that. Finally, note that the operator $f \mapsto Kf$ is *positive*: if $f \geq 0$ then $Kf \geq 0$. Here is the important summary of our results when the kernel is bounded.

If K is a bounded kernel from (S, \mathcal{S}) to (T, \mathcal{T}) , then $f \mapsto Kf$ is a bounded, linear transformation from $\mathcal{B}(T)$ to $\mathcal{B}(S)$ and $\|K\|$ is the norm of the transformation.

The *commutative property* for the product of kernels fails with a passion. If K and L are kernels, then depending on the measurable spaces, KL may be well defined, but not LK . Even if both products are defined, they may be kernels from or to different measurable spaces. Even if both are defined from and to the same measurable spaces, it may well happen that $KL \neq LK$. Some [examples](#) are given below

If K is a kernel on (S, \mathcal{S}) and $n \in \mathbb{N}$, we let $K^n = KK \cdots K$, the n -fold power of K . By convention, $K^0 = I$, the identity kernel on S .

Fixed points of the operators associated with a kernel turn out to be very important.

Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) .

1. A positive measure μ on (S, \mathcal{S}) such that $\mu K = \mu$ is said to be *invariant* for K .
2. A measurable function $f : T \rightarrow \mathbb{R}$ such that $Kf = f$ is said to be *invariant* for K

So in the language of linear algebra (or functional analysis), an invariant measure is a *left eigenvector* of the kernel, while an invariant function is a *right eigenvector* of the kernel, both corresponding to the eigenvalue 1. By our results above, if μ and ν are invariant measures and $c \in [0, \infty)$, then $\mu + \nu$ and $c\mu$ are also invariant. Similarly, if f and g are invariant functions and $c \in \mathbb{R}$, then $f + g$ and cf are also invariant.

Of course we are particularly interested in *probability* kernels.

Suppose that P is a probability kernel from (R, \mathcal{R}) to (S, \mathcal{S}) and that Q is a probability kernel from (S, \mathcal{S}) to (T, \mathcal{T}) . Suppose also that μ is a probability measure on (R, \mathcal{R}) . Then

1. PQ is a probability kernel from (R, \mathcal{R}) to (T, \mathcal{T}) .
2. μP is a probability measure on (S, \mathcal{S}) .

Proof

1. We know that PQ is a kernel from (R, \mathcal{R}) to (T, \mathcal{T}) . So we just need to note that

$$PQ(T) = \int_S P(x, dy)Q(y, T) = \int_S P(x, dy) = P(x, S) = 1, \quad x \in R \quad (4.13.7)$$

2. We know that μP is a positive measure on (S, \mathcal{S}) . So we just need to note that

$$\mu P(S) = \int_R \mu(dx) P(x, S) = \int_R \mu(dx) = \mu(R) = 1 \quad (4.13.8)$$

As a corollary, it follows that if P is a probability kernel on (S, \mathcal{S}) , then so is P^n for $n \in \mathbb{N}$.

The operators associated with a kernel are of fundamental importance, and we can easily recover the kernel from the operators. Suppose that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) , and let $x \in S$ and $A \in \mathcal{T}$. Then trivially, $K \mathbf{1}_A(x) = K(x, A)$ where as usual, $\mathbf{1}_A$ is the indicator function of A . Trivially also $\delta_x K(A) = K(x, A)$ where δ_x is point mass at x .

Kernel Functions

Usually our *measurable* spaces are in fact *measure* spaces, with natural measures associated with the spaces, as in the special cases described in (1). When we start with measure spaces, kernels are usually constructed from *density functions* in much the same way that positive measures are defined from density functions.

Suppose that $(S, \mathcal{S}, \lambda)$ and (T, \mathcal{T}, μ) are measure spaces. As usual, $S \times T$ is given the product σ -algebra $\mathcal{S} \otimes \mathcal{T}$. If $k : S \times T \rightarrow [0, \infty)$ is measurable, then the function K defined as follows is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) :

$$K(x, A) = \int_A k(x, y) \mu(dy), \quad x \in S, A \in \mathcal{T} \quad (4.13.9)$$

Proof

The measurability of $x \mapsto K(x, A) = \int_A k(x, y) \mu(dy)$ for $A \in \mathcal{T}$ follows from a basic property of the integral. The fact that $A \mapsto K(x, A) = \int_A k(x, y) \mu(dy)$ is a positive measure on \mathcal{T} for $x \in S$ also follows from a basic property of the integral. In fact, $y \mapsto k(x, y)$ is the density of this measure with respect to μ .

Clearly the kernel K depends on the positive measure μ on (T, \mathcal{T}) as well as the function k , while the measure λ on (S, \mathcal{S}) plays no role (and so is not even necessary). But again, our point of view is that the spaces have fixed, natural measures. Appropriately enough, the function k is called a *kernel density function* (with respect to μ), or simply a *kernel function*.

Suppose again that $(S, \mathcal{S}, \lambda)$ and (T, \mathcal{T}, μ) are measure spaces. Suppose also K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) with kernel function k . If $f : T \rightarrow \mathbb{R}$ is measurable, then, assuming that the integrals exists,

$$Kf(x) = \int_S k(x, y) f(y) \mu(dy), \quad x \in S \quad (4.13.10)$$

Proof

This follows since the function $y \mapsto k(x, y)$ is the density of the measure $A \mapsto K(x, A)$ with respect to μ :

$$Kf(x) = \int_S K(x, dy) f(y) = \int_S k(x, y) f(y) \mu(dy), \quad x \in S \quad (4.13.11)$$

A kernel function defines an operator on the left with functions on S in a completely analogous way to the operator on the right above with functions on T .

Suppose again that $(S, \mathcal{S}, \lambda)$ and (T, \mathcal{T}, μ) are measure spaces, and that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) with kernel function k . If $f : S \rightarrow \mathbb{R}$ is measurable, then the function $fK : T \rightarrow \mathbb{R}$ defined as follows is also measurable, assuming that the integrals exists

$$fK(y) = \int_S \lambda(dx) f(x) k(x, y), \quad y \in T \quad (4.13.12)$$

The operator defined above depends on the measure λ on (S, \mathcal{S}) as well as the kernel function k , while the measure μ on (T, \mathcal{T}) plays no role (and so is not even necessary). But again, our point of view is that the spaces have fixed, natural measures. Here is how our new operation on the left with *functions* relates to our old operation on the left with *measures*.

Suppose again that $(S, \mathcal{S}, \lambda)$ and (T, \mathcal{T}, μ) are measure spaces, and that K is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) with kernel function k . Suppose also that $f : S \rightarrow [0, \infty)$ is measurable, and let ρ denote the measure on (S, \mathcal{S}) that has density f with respect to λ . Then fK is the density of the measure ρK with respect to μ .

Proof

The main tool, as usual, is an interchange of integrals. For $B \in \mathcal{T}$,

$$\begin{aligned}\rho K(B) &= \int_S \rho(dx) K(x, B) = \int_S f(x) K(x, B) \lambda(dx) = \int_S f(x) \left[\int_B k(x, y) \mu(dy) \right] \lambda(dx) \\ &= \int_B \left[\int_S f(x) k(x, y) \lambda(dx) \right] \mu(dy) = \int_B fK(y) \mu(dy)\end{aligned}$$

As always, we are particularly interested in stochastic kernels. With a kernel function, we can have *doubly* stochastic kernels.

Suppose again that $(S, \mathcal{S}, \lambda)$ and (T, \mathcal{T}, μ) are measure spaces and that $k : S \times T \rightarrow [0, \infty)$ is measurable. Then k is a *double stochastic kernel function* if

1. $\int_T k(x, y) \mu(dy) = 1$ for $x \in S$
2. $\int_S \lambda(dx) k(x, y) = 1$ for $y \in S$

Of course, condition (a) simply means that the kernel associated with k is a stochastic kernel according to our original definition.

The most common and important special case is when the two spaces are the same. Thus, if $(S, \mathcal{S}, \lambda)$ is a measure space and $k : S \times S \rightarrow [0, \infty)$ is measurable, then we have an operator K that operates on the left and on the right with measurable functions $f : S \rightarrow \mathbb{R}$:

$$\begin{aligned}fK(y) &= \int_S \lambda(dx) f(x) k(x, y), \quad y \in S \\ Kf(x) &= \int_S k(x, y) f(y) \lambda(dy), \quad x \in S\end{aligned}$$

If f is nonnegative and μ is the measure on with density function f , then fK is the density function of the measure μK (both with respect to λ).

Suppose again that $(S, \mathcal{S}, \lambda)$ is a measure space and $k : S \times S \rightarrow [0, \infty)$ is measurable. Then k is *symmetric* if $k(x, y) = k(y, x)$ for all $(x, y) \in S^2$.

Of course, if k is a symmetric, stochastic kernel function on $(S, \mathcal{S}, \lambda)$ then k is doubly stochastic, but the converse is not true.

Suppose that $(R, \mathcal{R}, \lambda)$, (S, \mathcal{S}, μ) , and (T, \mathcal{T}, ρ) are measure spaces. Suppose also that K is a kernel from (R, \mathcal{R}) to (S, \mathcal{S}) with kernel function k , and that L is a kernel from (S, \mathcal{S}) to (T, \mathcal{T}) with kernel function l . Then the kernel KL from (R, \mathcal{R}) to (T, \mathcal{T}) has density kl given by

$$kl(x, z) = \int_S k(x, y) l(y, z) \mu(dy), \quad (x, z) \in R \times T \quad (4.13.13)$$

Proof

Once again, the main tool is an interchange of integrals via Fubini's theorem. Let $x \in R$ and $B \in \mathcal{T}$. Then

$$\begin{aligned}KL(x, B) &= \int_S K(x, dy) L(y, B) = \int_S k(x, y) L(y, B) \mu(dy) \\ &= \int_S k(x, y) \left[\int_B l(y, z) \rho(dz) \right] \mu(dy) = \int_B \left[\int_S k(x, y) l(y, z) \mu(dy) \right] \rho(dz) = \int_B kl(x, z) \rho(dz)\end{aligned}$$

Examples and Special Cases

The Discrete Case

In this subsection, we assume that the measure spaces are discrete, as described in (1). Since the σ -algebra (all subsets) and the measure (counting measure) are understood, we don't need to reference them. Recall that integrals with respect to counting measure are sums. Suppose now that K is a kernel from the discrete space S to the discrete space T . For $x \in S$ and $y \in T$, let $K(x, y) = K(x, \{y\})$. Then more generally,

$$K(x, A) = \sum_{y \in A} K(x, y), \quad x \in S, A \subseteq T \quad (4.13.14)$$

The function $(x, y) \mapsto K(x, y)$ is simply the kernel function of the kernel K , as defined above, but in this case we usually don't bother with using a different symbol for the function as opposed to the kernel. The function K can be thought of as a *matrix*, with rows indexed by S and columns indexed by T (and so an infinite matrix if S or T is countably infinite). With this interpretation, all of the operations defined above can be thought of as matrix operations. If $f : T \rightarrow \mathbb{R}$ and f is thought of as a column vector indexed by T , then Kf is simply the ordinary product of the matrix K and the vector f ; the product is a column vector indexed by S :

$$Kf(x) = \sum_{y \in S} K(x, y)f(y), \quad x \in S \quad (4.13.15)$$

Similarly, if $f : S \rightarrow \mathbb{R}$ and f is thought of as a row vector indexed by S , then fK is simple the ordinary product of the vector f and the matrix K ; the product is a row vector indexed by T :

$$fK(y) = \sum_{x \in S} f(x)K(x, y), \quad y \in T \quad (4.13.16)$$

If L is another kernel from T to another discrete space U , then as functions, KL is the simply the matrix product of K and L :

$$KL(x, z) = \sum_{y \in T} K(x, y)L(y, z), \quad (x, z) \in S \times U \quad (4.13.17)$$

Let $S = \{1, 2, 3\}$ and $T = \{1, 2, 3, 4\}$. Define the kernel K from S to T by $K(x, y) = x + y$ for $(x, y) \in S \times T$. Define the function f on S by $f(x) = x!$ for $x \in S$, and define the function g on T by $g(y) = y^2$ for $y \in T$. Compute each of the following using matrix algebra:

1. fK
2. Kg

Answer

In matrix form,

$$K = \begin{bmatrix} 2 & 3 & 4 & 5 \\ 3 & 4 & 5 & 6 \\ 4 & 5 & 6 & 7 \end{bmatrix}, \quad f = [1 \quad 2 \quad 6], \quad g = \begin{bmatrix} 1 \\ 4 \\ 9 \\ 16 \end{bmatrix} \quad (4.13.18)$$

1. As a row vector indexed by T , the product is $fK = [32 \quad 41 \quad 50 \quad 59]$
2. As a column vector indexed by S ,

$$Kg = \begin{bmatrix} 130 \\ 160 \\ 190 \end{bmatrix} \quad (4.13.19)$$

Let $R = \{0, 1\}$, $S = \{a, b\}$, and $T = \{1, 2, 3\}$. Define the kernel K from R to S , the kernel L from S to S and the kernel M from S to T in matrix form as follows:

$$K = \begin{bmatrix} 1 & 4 \\ 2 & 3 \end{bmatrix}, \quad L = \begin{bmatrix} 2 & 2 \\ 1 & 5 \end{bmatrix}, \quad M = \begin{bmatrix} 1 & 0 & 2 \\ 0 & 3 & 1 \end{bmatrix} \quad (4.13.20)$$

Compute each of the following kernels, or explain why the operation does not make sense:

1. KL
2. LK
3. K^2
4. L^2
5. KM
6. LM

Proof

Note that these are not just abstract matrices, but rather have rows and columns indexed by the appropriate spaces. So the products make sense only when the spaces match appropriately; it's not just a matter of the number of rows and columns.

1. KL is the kernel from R to S given by

$$KL = \begin{bmatrix} 6 & 22 \\ 7 & 19 \end{bmatrix} \quad (4.13.21)$$

2. LK is not defined since the column space S of L is not the same as the row space R of K .
3. K^2 is not defined since the row space R is not the same as the column space S .
4. L^2 is the kernel from S to S given by

$$L^2 = \begin{bmatrix} 6 & 14 \\ 7 & 27 \end{bmatrix} \quad (4.13.22)$$

5. KM is the kernel from R to T given by

$$KM = \begin{bmatrix} 1 & 12 & 6 \\ 2 & 9 & 7 \end{bmatrix} \quad (4.13.23)$$

6. LM is the kernel from S to T given by

$$LM = \begin{bmatrix} 2 & 6 & 6 \\ 1 & 15 & 7 \end{bmatrix} \quad (4.13.24)$$

Conditional Probability

An important class of probability kernels arises from the distribution of one random variable, conditioned on the value of another random variable. In this subsection, suppose that $(\Omega, \mathcal{F}, \mathbb{P})$ is a probability space, and that (S, \mathcal{S}) and (T, \mathcal{T}) are measurable spaces. Further, suppose that X and Y are random variables defined on the probability space, with X taking values in S and that Y taking values in T . Informally, X and Y are random variables defined on the same underlying random experiment.

The function P defined as follows is a probability kernel from (S, \mathcal{S}) to (T, \mathcal{T}) , known as the *conditional probability kernel* of Y given X .

$$P(x, A) = \mathbb{P}(Y \in A \mid X = x), \quad x \in S, A \in \mathcal{T} \quad (4.13.25)$$

Proof

Recall that for $A \in \mathcal{T}$, the conditional probability $\mathbb{P}(Y \in A \mid X)$ is itself a random variable, and is measurable with respect to $\sigma(X)$. That is, $\mathbb{P}(Y \in A \mid X) = P(X, A)$ for some measurable function $x \mapsto P(x, A)$ from S to $[0, 1]$. Then, by definition, $\mathbb{P}(Y \in A \mid X = x) = P(x, A)$. Trivially, of course, $A \mapsto P(x, A)$ is a probability measure on (T, \mathcal{T}) for $x \in S$.

The operators associated with this kernel have natural interpretations.

Let P be the conditional probability kernel of Y given X .

1. If $f : T \rightarrow \mathbb{R}$ is measurable, then $Pf(x) = \mathbb{E}[f(Y) \mid X = x]$ for $x \in S$ (assuming as usual that the expected value exists).
2. If μ is the probability distribution of X then μP is the probability distribution of Y .

Proof

These are basic results that we have already studied, dressed up in new notation.

1. Since $A \mapsto P(x, A)$ is the conditional distribution of Y given $X = x$,

$$\mathbb{E}[f(Y) \mid X = x] = \int_S P(x, dy) f(y) = P f(x) \quad (4.13.26)$$

2. Let $A \in \mathcal{T}$. Conditioning on X gives

$$\mathbb{P}(Y \in A) = \mathbb{E}[\mathbb{P}(Y \in A \mid X)] = \int_S \mu(dx) P(Y \in A \mid X = x) = \int_S \mu(dx) P(x, A) = \mu P(A) \quad (4.13.27)$$

As in the general discussion above, the measurable spaces (S, \mathcal{S}) and (T, \mathcal{T}) are usually *measure* spaces with natural measures attached. So the conditional probability distributions are often given via conditional probability density functions, which then play the role of kernel functions. The next two exercises give examples.

Suppose that X and Y are random variables for an experiment, taking values in \mathbb{R} . For $x \in \mathbb{R}$, the conditional distribution of Y given $X = x$ is normal with mean x and standard deviation 1. Use the notation and operations of this section for the following computations:

1. Give the kernel function for the conditional distribution of Y given X .
2. Find $\mathbb{E}(Y^2 \mid X = x)$.
3. Suppose that X has the standard normal distribution. Find the probability density function of Y .

Answer

1. The kernel function (with respect to Lebesgue measure, of course) is

$$p(x, y) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(y-x)^2}, \quad x, y \in \mathbb{R} \quad (4.13.28)$$

2. Let $g(y) = y^2$ for $y \in \mathbb{R}$. Then $E(Y^2 \mid X = x) = P g(x) = 1 + x^2$ for $x \in \mathbb{R}$
3. The standard normal PDF f is given $f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ for $x \in \mathbb{R}$. Thus Y has PDF fP .

$$fP(y) \int_{-\infty}^{\infty} f(x) p(x, y) dx = \frac{1}{2\sqrt{\pi}} e^{-\frac{1}{4}y^2}, \quad y \in \mathbb{R} \quad (4.13.29)$$

This is the PDF of the normal distribution with mean 0 and variance 2.

Suppose that X and Y are random variables for an experiment, with X taking values in $\{a, b, c\}$ and Y taking values in $\{1, 2, 3, 4\}$. The kernel function of Y given X is as follows: $P(a, y) = 1/4$, $P(b, y) = y/10$, and $P(c, y) = y^2/30$, each for $y \in \{1, 2, 3, 4\}$.

1. Give the kernel P in matrix form and verify that it is a probability kernel.
2. Find fP where $f(a) = f(b) = f(c) = 1/3$. The result is the density function of Y given that X is uniformly distributed.
3. Find Pg where $g(y) = y$ for $y \in \{1, 2, 3, 4\}$. The resulting function is $\mathbb{E}(Y \mid X = x)$ for $x \in \{a, b, c\}$.

Answer

1. P is given in matrix form below. Note that the row sums are 1.

$$P = \begin{bmatrix} \frac{1}{4} & \frac{1}{4} & \frac{1}{4} & \frac{1}{4} \\ \frac{1}{10} & \frac{2}{10} & \frac{3}{10} & \frac{4}{10} \\ \frac{1}{30} & \frac{4}{30} & \frac{9}{30} & \frac{16}{30} \end{bmatrix} \quad (4.13.30)$$

2. In matrix form, $f = \begin{bmatrix} \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{bmatrix}$ and $fP = \begin{bmatrix} \frac{23}{180} & \frac{35}{180} & \frac{51}{180} & \frac{71}{180} \end{bmatrix}$.
3. In matrix form,

$$g = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \end{bmatrix}, \quad Pg = \begin{bmatrix} \frac{5}{2} \\ 3 \\ \frac{10}{3} \end{bmatrix} \quad (4.13.31)$$

Parametric Distributions

A parametric probability distribution also defines a probability kernel in a natural way, with the parameter playing the role of the kernel variable, and the distribution playing the role of the measure. Such distributions are usually defined in terms of a parametric density function which then defines a kernel function, again with the parameter playing the role of the first argument and the variable the role of the second argument. If the parameter is thought of as a given value of another random variable, as in Bayesian analysis, then there is considerable overlap with the previous subsection. In most cases, (and in particular in the examples below), the spaces involved are either discrete or Euclidean, as described in (1).

Consider the parametric family of exponential distributions. Let f denote the identity function on $(0, \infty)$.

1. Give the probability density function as a probability kernel function p on $(0, \infty)$.
2. Find Pf .
3. Find fP .
4. Find p^2 , the kernel function corresponding to the product kernel P^2 .

Answer

1. $p(r, x) = re^{-rx}$ for $r, x \in (0, \infty)$.
2. For $r \in (0, \infty)$,

$$Pf(r) = \int_0^\infty p(r, x)f(x) dx = \int_0^\infty xre^{-rx} dx = \frac{1}{r} \quad (4.13.32)$$

This is the mean of the exponential distribution.

3. For $x \in (0, \infty)$,

$$fP(x) = \int_0^\infty f(r)p(r, x) dr = \int_0^\infty r^2e^{-rx} dr = \frac{2}{x^3} \quad (4.13.33)$$

4. For $r, y \in (0, \infty)$,

$$p^2(r, y) = \int_0^\infty p(r, x)p(x, y) dx = \int_0^\infty rxe^{-(r+y)x} dx = \frac{r}{(r+y)^2} \quad (4.13.34)$$

Consider the parametric family of Poisson distributions. Let f be the identity function on \mathbb{N} and let g be the identity function on $(0, \infty)$.

1. Give the probability density function p as a probability kernel function from $(0, \infty)$ to \mathbb{N} .
2. Show that $Pf = g$.
3. Show that $gP = f$.

Answer

1. $p(r, n) = e^{-r} \frac{r^n}{n!}$ for $r \in (0, \infty)$ and $n \in \mathbb{N}$.
2. For $r \in (0, \infty)$, $Pf(r)$ is the mean of the Poisson distribution with parameter r :

$$Pf(r) = \sum_{n=0}^\infty p(r, n)f(n) = \sum_{n=0}^\infty ne^{-r} \frac{r^n}{n!} = r \quad (4.13.35)$$

3. For $n \in \mathbb{N}$,

$$gP(n) = \int_0^\infty g(r)p(r, n) dr = \int_0^\infty e^{-r} \frac{r^{n+1}}{n!} dr = n \quad (4.13.36)$$

Clearly the Poisson distribution has some very special and elegant properties. The next family of distributions also has some very special properties. Compare this exercise with the exercise (30).

Consider the family of normal distributions, parameterized by the mean and with variance 1.

1. Give the probability density function as a probability kernel function p on \mathbb{R} .

2. Show that p is symmetric.
3. Let f be the identity function on \mathbb{R} . Show that $Pf = f$ and $fP = f$.
4. For $n \in \mathbb{N}$, find p^n the kernel function for the operator P^n .

Answer

1. For $\mu, x \in \mathbb{R}$,

$$p(\mu, x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x-\mu)^2} \quad (4.13.37)$$

That is, $x \mapsto p(x, \mu)$ is the normal probability density function with mean μ and variance 1.

2. Note that $p(\mu, x) = p(x, \mu)$ for $\mu, x \in \mathbb{R}$. So $\mu \mapsto p(\mu, x)$ is the normal probability density function with mean x and variance 1.
3. Since $f(x) = x$ for $x \in \mathbb{R}$, this follows from the previous two parts: $Pf(\mu) = \mu$ for $\mu \in \mathbb{R}$ and $fP(x) = x$ for $x \in \mathbb{R}$
4. For $\mu, y \in \mathbb{R}$,

$$p^2(\mu, x) = \int_{-\infty}^{\infty} p(\mu, t)p(t, y) dt = \frac{1}{\sqrt{4\pi}} e^{-\frac{1}{4}(x-\mu)^2} \quad (4.13.38)$$

so that $x \mapsto p^2(\mu, x)$ is the normal PDF with mean μ and variance 2. By induction,

$$p^n(\mu, x) = \frac{1}{\sqrt{2\pi n}} e^{-\frac{1}{2n}(x-\mu)^2} \quad (4.13.39)$$

for $n \in \mathbb{N}_+$ and $\mu, x \in \mathbb{R}$. Thus $x \mapsto p^n(\mu, x)$ is the normal PDF with mean μ and variance n .

For each of the following special distributions, express the probability density function as a probability kernel function. Be sure to specify the parameter spaces.

1. The general normal distribution on \mathbb{R} .
2. The beta distribution on $(0, 1)$.
3. The negative binomial distribution on \mathbb{N} .

Answer

1. The normal distribution with mean μ and standard deviation σ defines a kernel function p from $\mathbb{R} \times (0, \infty)$ to \mathbb{R} given by

$$p[(\mu, \sigma), x] = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\left(\frac{x-\mu}{\sigma}\right)^2\right] \quad (4.13.40)$$

2. The beta distribution with left parameter a and right parameter b defines a kernel function p from $(0, \infty)^2$ to $(0, 1)$ given by

$$p[(a, b), x] = \frac{1}{B(a, b)} x^{a-1} y^{b-1} \quad (4.13.41)$$

where B is the beta function.

3. The negative binomial distribution with stopping parameter k and success parameter α defines a kernel function p from $(0, \infty) \times (0, 1)$ to \mathbb{N} given by

$$p[(n, \alpha), k] = \binom{n+k-1}{n} \alpha^k (1-\alpha)^n \quad (4.13.42)$$

CHAPTER OVERVIEW

5: Special Distributions

In this chapter, we study several general families of probability distributions and a number of special parametric families of distributions. Unlike the other expository chapters in this text, the sections are not linearly ordered and so this chapter serves primarily as a reference. You may want to study these topics as the need arises.

First, we need to discuss what makes a probability distribution *special* in the first place. In some cases, a distribution may be important because it is connected with other special distributions in interesting ways (via transformations, limits, conditioning, etc.). In some cases, a parametric family may be important because it can be used to model a wide variety of random phenomena. This may be the case because of fundamental underlying principles, or simply because the family has a rich collection of probability density functions with a small number of parameters (usually 3 or less). As a general philosophical principle, we try to model a random process with as few parameters as possible; this is sometimes referred to as the principle of *parsimony of parameters*. In turn, this is a special case of *Ockham's razor*, named in honor of William of Ockham, the principle that states that one should use the simplest model that adequately describes a given phenomenon. Parsimony is important because often the parameters are not known and must be estimated.

In many cases, a special parametric family of distributions will have one or more distinguished *standard members*, corresponding to specified values of some of the parameters. Usually the standard distributions will be mathematically simplest, and often other members of the family can be constructed from the standard distributions by simple transformations on the underlying standard random variable.

An incredible variety of special distributions have been studied over the years, and new ones are constantly being added to the literature. To truly deserve the adjective *special*, a distribution should have a certain level of mathematical elegance and economy, and should arise in interesting and diverse applications.

5.1: Location-Scale Families

General Theory

As usual, our starting point is a random experiment modeled by a probability space $(\Omega, \mathcal{F}, \mathbb{P})$, so that Ω is the set of outcomes, \mathcal{F} the collection of events, and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) . In this section, we assume that we fixed random variable Z defined on the probability space, taking values in \mathbb{R} .

Definition

For $a \in \mathbb{R}$ and $b \in (0, \infty)$, let $X = a + bZ$. The two-parameter family of distributions associated with X is called the *location-scale family* associated with the given distribution of Z . Specifically, a is the *location parameter* and b the *scale parameter*.

Thus a *linear transformation*, with positive slope, of the underlying random variable Z creates a *location-scale family* for the underlying distribution. In the special case that $b = 1$, the one-parameter family is called the *location family* associated with the given distribution, and in the special case that $a = 0$, the one-parameter family is called the *scale family* associated with the given distribution. Scale transformations, as the name suggests, occur naturally when physical units are changed. For example, if a random variable represents the length of an object, then a change of units from meters to inches corresponds to a scale transformation. Location transformations often occur when the zero reference point is changed, in measuring distance or time, for example. Location-scale transformations can also occur with a change of physical units. For example, if a random variable represents the temperature of an object, then a change of units from Fahrenheit to Celsius corresponds to a location-scale transformation.

Distribution Functions

Our goal is to relate various functions that determine the distribution of $X = a + bZ$ to the corresponding functions for Z . First we consider the (cumulative) distribution function.

If Z has distribution function G then X has distribution function F given by

$$F(x) = G\left(\frac{x-a}{b}\right), \quad x \in \mathbb{R} \quad (5.1.1)$$

Proof

For $x \in \mathbb{R}$

$$F(x) = \mathbb{P}(X \leq x) = \mathbb{P}(a + bZ \leq x) = \mathbb{P}\left(Z \leq \frac{x-a}{b}\right) = G\left(\frac{x-a}{b}\right) \quad (5.1.2)$$

Next we consider the probability density function. The results are a bit different for discrete distributions and continuous distribution, not surprising since the density function has different meanings in these two cases.

If Z has a discrete distribution with probability density function g then X also has a discrete distribution, with probability density function f given by

$$f(x) = g\left(\frac{x-a}{b}\right), \quad x \in \mathbb{R} \quad (5.1.3)$$

Proof

Z takes values in a countable subset $S \subset \mathbb{R}$ and hence X takes values in $T = \{a + bz : z \in S\}$, which is also countable. Moreover

$$f(x) = \mathbb{P}(X = x) = \mathbb{P}\left(Z = \frac{x-a}{b}\right) = g\left(\frac{x-a}{b}\right), \quad x \in \mathbb{R} \quad (5.1.4)$$

If Z has a continuous distribution with probability density function g , then X also has a continuous distribution, with probability density function f given by

$$f(x) = \frac{1}{b} g\left(\frac{x-a}{b}\right), \quad x \in \mathbb{R} \quad (5.1.5)$$

1. For the location family associated with g , the graph of f is obtained by shifting the graph of g , a units to the right if $a > 0$ and $-a$ units to the left if $a < 0$.
2. For the scale family associated with g , if $b > 1$, the graph of f is obtained from the graph of g by stretching horizontally and compressing vertically, by a factor of b . If $0 < b < 1$, the graph of f is obtained from the graph of g by compressing horizontally and stretching vertically, by a factor of b .

Proof

First note that $\mathbb{P}(X = x) = \mathbb{P}\left(Z = \frac{x-a}{b}\right) = 0$, so X has a continuous distribution. Typically, Z takes values in an interval of \mathbb{R} and thus so does X . The formula for the density function follows by taking derivatives of the [distribution function](#) above, since $f = F'$ and $g = G'$.

If Z has a mode at z , then X has a mode at $x = a + bz$.

Proof

This follows from [density function](#) in the discrete case or the [density function](#) in the continuous case. If g has a maximum at z then f has a maximum at $x = a + bz$.

Next we relate the quantile functions of Z and X .

If G and F are the distribution functions of Z and X , respectively, then

1. $F^{-1}(p) = a + b G^{-1}(p)$ for $p \in (0, 1)$
2. If z is a quantile of order p for Z then $x = a + bz$ is a quantile of order p for X .

Proof

These results follow from the [distribution function](#) above.

Suppose now that Z has a continuous distribution on $[0, \infty)$, and that we think of Z as the failure time of a device (or the time of death of an organism). Let $X = bZ$ where $b \in [0, \infty)$, so that the distribution of X is the scale family associated with the distribution of Z . Then X also has a continuous distribution on $[0, \infty)$ and can also be thought of as the failure time of a device (perhaps in different units).

Let G^c and F^c denote the reliability functions of Z and X respectively, and let r and R denote the failure rate functions of Z and X , respectively. Then

1. $F^c(x) = G^c(x/b)$ for $x \in [0, \infty)$
2. $R(x) = \frac{1}{b} r\left(\frac{x}{b}\right)$ for $x \in [0, \infty)$

Proof

Recall that $G^c = 1 - G$, $F^c = 1 - F$, $r = g/\bar{G}$, and $R = f/\bar{F}$. Thus the results follow from the [distribution function](#) and the [density function](#) above.

Moments

The following theorem relates the mean, variance, and standard deviation of Z and X .

As before, suppose that $X = a + bZ$. Then

1. $\mathbb{E}(X) = a + b \mathbb{E}(Z)$
2. $\text{var}(X) = b^2 \text{var}(Z)$
3. $\text{sd}(X) = b \text{sd}(Z)$

Proof

These result follow immediately from basic properties of expected value and variance.

Recall that the *standard score* of a random variable is obtained by subtracting the mean and dividing by the standard deviation. The standard score is dimensionless (that is, has no physical units) and measures the distance from the mean to the random variable in standard deviations. Since location-scale families essentially correspond to a change of units, it's not surprising that the standard score is unchanged by a location-scale transformation.

The standard scores of X and Z are the same:

$$\frac{X - \mathbb{E}(X)}{\text{sd}(X)} = \frac{Z - \mathbb{E}(Z)}{\text{sd}(Z)} \quad (5.1.6)$$

Proof

From the [mean and variance](#) above:

$$\frac{X - \mathbb{E}(X)}{\text{sd}(X)} = \frac{a + bZ - [a + b\mathbb{E}(Z)]}{b\text{sd}(Z)} = \frac{Z - \mathbb{E}(Z)}{\text{sd}(Z)} \quad (5.1.7)$$

Recall that the skewness and kurtosis of a random variable are the third and fourth moments, respectively, of the standard score. Thus it follows from the previous result that skewness and kurtosis are unchanged by location-scale transformations: $\text{skew}(X) = \text{skew}(Z)$, $\text{kurt}(X) = \text{kurt}(Z)$.

We can represent the moments of X (about 0) to those of Z by means of the binomial theorem:

$$\mathbb{E}(X^n) = \sum_{k=0}^n \binom{n}{k} b^k a^{n-k} \mathbb{E}(Z^k), \quad n \in \mathbb{N} \quad (5.1.8)$$

Of course, the moments of X about the location parameter a have a simple representation in terms of the moments of Z about 0:

$$\mathbb{E}[(X - a)^n] = b^n \mathbb{E}(Z^n), \quad n \in \mathbb{N} \quad (5.1.9)$$

The following exercise relates the moment generating functions of Z and X .

If Z has moment generating function m then X has moment generating function M given by

$$M(t) = e^{at} m(bt) \quad (5.1.10)$$

Proof

$$M(t) = \mathbb{E}(e^{tX}) = \mathbb{E}[e^{t(a+bZ)}] = e^{ta} \mathbb{E}(e^{tbZ}) = e^{at} m(bt) \quad (5.1.11)$$

Type

As we noted earlier, two probability distributions that are related by a location-scale transformation can be thought of as governing the same underlying random quantity, but in different physical units. This relationship is important enough to deserve a name.

Suppose that P and Q are probability distributions on \mathbb{R} with distribution functions F and G , respectively. Then P and Q are of the same *type* if there exist constants $a \in \mathbb{R}$ and $b \in (0, \infty)$ such that

$$F(x) = G\left(\frac{x - a}{b}\right), \quad x \in \mathbb{R} \quad (5.1.12)$$

Being of the same type is an equivalence relation on the collection of probability distributions on \mathbb{R} . That is, if P , Q , and R are probability distribution on \mathbb{R} then

1. P is the same type as P (the *reflexive* property).
2. If P is the same type as Q then Q is the same type as P (the *symmetric* property).
3. If P is the same type as Q , and Q is the same type as R , then P is the same type as R (the *transitive* property).

Proof

Let F , G , and H denote the distribution functions of P , Q , and R respectively.

1. This is trivial, of course, since we can take $a = 0$ and $b = 1$.

2. Suppose there exists $a \in \mathbb{R}$ and $b \in (0, \infty)$ such that $F(x) = G\left(\frac{x-a}{b}\right)$ for $x \in \mathbb{R}$. Then

$$G(x) = F(a + bx) = F\left(\frac{x - (-a/b)}{1/b}\right) \text{ for } x \in \mathbb{R}.$$

3. Suppose there exists $a, c \in \mathbb{R}$ and $b, d \in (0, \infty)$ such that $F(x) = G\left(\frac{x-a}{b}\right)$ and $G(x) = H\left(\frac{x-c}{d}\right)$ for $x \in \mathbb{R}$. Then

$$F(x) = H\left(\frac{x - (a+bc)}{bd}\right) \text{ for } x \in \mathbb{R}.$$

So, the collection of probability distributions on \mathbb{R} is partitioned into mutually exclusive equivalence classes, where the distributions in each class are all of the same type.

Examples and Applications

Special Distributions

Many of the special parametric families of distributions studied in this chapter and elsewhere in this text are location and/or scale families.

The [arcsine distribution](#) is a location-scale family.

The [Cauchy distribution](#) is a location-scale family.

The [exponential distribution](#) is a scale family.

The [exponential-logarithmic distribution](#) is a scale family for each value of the shape parameter.

The [extreme value distribution](#) is a location-scale family.

The [gamma distribution](#) is a scale family for each value of the shape parameter.

The [Gompertz distribution](#) is a scale family for each value of the shape parameter.

The [half-normal distribution](#) is a scale family.

The [hyperbolic secant](#) distribution is a location-scale family.

The [Lévy distribution](#) is a location scale family.

The [logistic distribution](#) is a location-scale family.

The [log-logistic distribution](#) is a scale family for each value of the shape parameter.

The [Maxwell distribution](#) is a scale family.

The [normal distribution](#) is a location-scale family.

The [Pareto distribution](#) is a scale family for each value of the shape parameter.

The [Rayleigh distribution](#) is a scale family.

The [semicircle distribution](#) is a location-scale family.

The [triangle distribution](#) is a location-scale family for each value of the shape parameter.

The [uniform distribution](#) on an interval is a location-scale family.

The [U-power distribution](#) is a location-scale family for each value of the shape parameter.

The [Weibull distribution](#) is a scale family for each value of the shape parameter.

The [Wald distribution](#) is a scale family, although in the usual formulation, neither of the parameters is a scale parameter.

5.2: General Exponential Families

Basic Theory

Definition

We start with a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ as a model for a random experiment. So as usual, Ω is the set of outcomes, \mathcal{F} the σ -algebra of events, and \mathbb{P} the probability measure on the sample space (Ω, \mathcal{F}) . For the general formulation that we want in this section, we need two additional spaces, a measure space (S, \mathcal{S}, μ) (where the probability distributions will live) and a measurable space (T, \mathcal{T}) (serving the role of a *parameter space*). Typically, these spaces fall into our two standard categories. Specifically, the measure space is usually one of the following:

- *Discrete.* S is countable, \mathcal{S} is the collection of all subsets of S , and $\mu = \#$ is counting measure.
- *Euclidean.* S is a sufficiently nice Borel measurable subset of \mathbb{R}^n for some $n \in \mathbb{N}_+$, \mathcal{S} is the σ -algebra of Borel measurable subsets of S , and $\mu = \lambda_n$ is n -dimensional Lebesgue measure.

Similarly, the parameter space (T, \mathcal{T}) is usually either discrete, so that T is countable and \mathcal{T} the collection of all subsets of T , or Euclidean so that T is a sufficiently nice Borel measurable subset of \mathbb{R}^m for some $m \in \mathbb{N}_+$ and \mathcal{T} is the σ -algebra of Borel measurable subsets of T .

Suppose now that X is random variable defined on the probability space, taking values in S , and that the distribution of X depends on a parameter $\theta \in T$. For $\theta \in T$ we assume that the distribution of X has probability density function f_θ with respect to μ .

for $k \in \mathbb{N}_+$, the family of distributions of X is a k -parameter *exponential family* if

$$f_\theta(x) = \alpha(\theta) g(x) \exp\left(\sum_{i=1}^k \beta_i(\theta) h_i(x)\right); \quad x \in S, \theta \in T \quad (5.2.1)$$

where α and $(\beta_1, \beta_2, \dots, \beta_k)$ are measurable functions from T into \mathbb{R} , and where g and (h_1, h_2, \dots, h_k) are measurable functions from S into \mathbb{R} . Moreover, k is assumed to be the smallest such integer.

1. The parameters $(\beta_1(\theta), \beta_2(\theta), \dots, \beta_k(\theta))$ are called the *natural parameters* of the distribution.
2. the random variables $(h_1(X), h_2(X), \dots, h_k(X))$ are called the *natural statistics* of the distribution.

Although the definition may look intimidating, exponential families are useful because many important theoretical results in statistics hold for exponential families, and because many special parametric families of distributions turn out to be exponential families. It's important to emphasize that the representation of $f_\theta(x)$ given in the definition must hold for all $x \in S$ and $\theta \in T$. If the representation only holds for a set of $x \in S$ that depends on the particular $\theta \in T$, then the family of distributions is not a general exponential family.

The next result shows that if we sample from the distribution of an exponential family, then the distribution of the random sample is itself an exponential family with the same natural parameters.

Suppose that the distribution of random variable X is a k -parameter exponential family with natural parameters $(\beta_1(\theta), \beta_2(\theta), \dots, \beta_k(\theta))$, and natural statistics $(h_1(X), h_2(X), \dots, h_k(X))$. Let $\mathbf{X} = (X_1, X_2, \dots, X_n)$ be a sequence of n independent random variables, each with the same distribution as X . Then \mathbf{X} is a k -parameter exponential family with natural parameters $(\beta_1(\theta), \beta_2(\theta), \dots, \beta_k(\theta))$, and natural statistics

$$u_j(\mathbf{X}) = \sum_{i=1}^n h_j(X_i), \quad j \in \{1, 2, \dots, k\} \quad (5.2.2)$$

Proof

Let f_θ denote the PDF of X corresponding to the parameter value $\theta \in T$, so that $f_\theta(x)$ has the representation given in the [definition](#) for $x \in S$ and $\theta \in T$. Then for $\theta \in T$, $\mathbf{X} = (X_1, X_2, \dots, X_n)$ has PDF g_θ given by

$$g_\theta(x_1, x_2, \dots, x_n) = f_\theta(x_1) f_\theta(x_2) \cdots f_\theta(x_n), \quad (x_1, x_2, \dots, x_n) \in S^n \quad (5.2.3)$$

Substituting and simplifying gives the result.

Examples and Special Cases

Special Distributions

Many of the special distributions studied in this chapter are general exponential families, at least with respect to some of their parameters. On the other hand, most commonly, a parametric family fails to be a general exponential family because the support set depends on the parameter. The following theorems give a number of examples. Proofs will be provided in the individual sections.

The Bernoulli distribution is a one parameter exponential family in the success parameter $p \in [0, 1]$

The beta distribution is a two-parameter exponential family in the shape parameters $a \in (0, \infty)$, $b \in (0, \infty)$.

The beta prime distribution is a two-parameter exponential family in the shape parameters $a \in (0, \infty)$, $b \in (0, \infty)$.

The binomial distribution is a one-parameter exponential family in the success parameter $p \in [0, 1]$ for a fixed value of the trial parameter $n \in \mathbb{N}_+$.

The chi-square distribution is a one-parameter exponential family in the degrees of freedom $n \in (0, \infty)$.

The exponential distribution is a one-parameter exponential family (appropriately enough), in the rate parameter $r \in (0, \infty)$.

The gamma distribution is a two-parameter exponential family in the shape parameter $k \in (0, \infty)$ and the scale parameter $b \in (0, \infty)$.

The geometric distribution is a one-parameter exponential family in the success probability $p \in (0, 1)$.

The half normal distribution is a one-parameter exponential family in the scale parameter $\sigma \in (0, \infty)$

The Laplace distribution is a one-parameter exponential family in the scale parameter $b \in (0, \infty)$ for a fixed value of the location parameter $a \in \mathbb{R}$.

The Lévy distribution is a one-parameter exponential family in the scale parameter $b \in (0, \infty)$ for a fixed value of the location parameter $a \in \mathbb{R}$.

The logarithmic distribution is a one-parameter exponential family in the shape parameter $p \in (0, 1)$

The lognormal distribution is a two parameter exponential family in the shape parameters $\mu \in \mathbb{R}$, $\sigma \in (0, \infty)$.

The Maxwell distribution is a one-parameter exponential family in the scale parameter $b \in (0, \infty)$.

The k -dimensional multinomial distribution is a k -parameter exponential family in the probability parameters (p_1, p_2, \dots, p_k) for a fixed value of the trial parameter $n \in \mathbb{N}_+$.

The k -dimensional multivariate normal distribution is a $\frac{1}{2}(k^2 + 3k)$ -parameter exponential family with respect to the mean vector $\boldsymbol{\mu}$ and the variance-covariance matrix \mathbf{V} .

The negative binomial distribution is a one-parameter exponential family in the success parameter $p \in (0, 1)$ for a fixed value of the stopping parameter $k \in \mathbb{N}_+$.

The normal distribution is a two-parameter exponential family in the mean $\mu \in \mathbb{R}$ and the standard deviation $\sigma \in (0, \infty)$.

The Pareto distribution is a one-parameter exponential family in the shape parameter for a fixed value of the scale parameter.

The Poisson distribution is a one-parameter exponential family.

The Rayleigh distribution is a one-parameter exponential family.

The U-power distribution is a one-parameter exponential family in the shape parameter, for fixed values of the location and scale parameters.

The Weibull distribution is a one-parameter exponential family in the scale parameter for a fixed value of the shape parameter.

The zeta distribution is a one-parameter exponential family.

The Wald distribution is a two-parameter exponential family.

This page titled [5.2: General Exponential Families](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

5.3: Stable Distributions

This section discusses a theoretical topic that you may want to skip if you are a new student of probability.

Basic Theory

Stable distributions are an important general class of probability distributions on \mathbb{R} that are defined in terms of location-scale transformations. Stable distributions occur as limits (in distribution) of scaled and centered sums of independent, identically distributed variables. Such limits generalize the central limit theorem, and so stable distributions generalize the normal distribution in a sense. The pioneering work on stable distributions was done by Paul Lévy.

Definition

In this section, we consider real-valued random variables whose distributions are not degenerate (that is, not concentrated at a single value). After all, a random variable with a degenerate distribution is not really *random*, and so is not of much interest.

Random variable X has a *stable distribution* if the following condition holds: If $n \in \mathbb{N}_+$ and (X_1, X_2, \dots, X_n) is a sequence of independent variables, each with the same distribution as X , then $X_1 + X_2 + \dots + X_n$ has the same distribution as $a_n + b_n X$ for some $a_n \in \mathbb{R}$ and $b_n \in (0, \infty)$. If $a_n = 0$ for $n \in \mathbb{N}_+$ then the distribution of X is *strictly stable*.

1. The parameters a_n for $n \in \mathbb{N}_+$ are the *centering parameters*.
2. The parameters b_n for $n \in \mathbb{N}_+$ are the *norming parameters*.

Details

Since the distribution of X is not point mass at 0, note that if the distribution of $a + bX$ is the same as the distribution of $c + dX$ for some $a, c \in \mathbb{R}$ and $b, d \in (0, \infty)$, then $a = c$ and $b = d$. Thus, the centering parameters a_n and the norming parameters b_n are uniquely defined for $n \in \mathbb{N}_+$.

Recall that two distributions on \mathbb{R} that are related by a location-scale transformation are said to be of the *same type*, and that *being of the same type* defines an equivalence relation on the class of distributions on \mathbb{R} . With this terminology, the definition of stability has a more elegant expression: X has a stable distribution if the sum of a finite number of independent copies of X is of the same type as X . As we will see, the norming parameters are more important than the centering parameters, and in fact, only certain norming parameters can occur.

Basic Properties

We start with some very simple results that follow easily from the definition, before moving on to the deeper results.

Suppose that X has a stable distribution with mean μ and finite variance. Then the norming parameters are \sqrt{n} and the centering parameters are $(n - \sqrt{n})\mu$ for $n \in \mathbb{N}_+$.

Proof

As usual, let a_n and b_n denote the centering and norming parameters of X for $n \in \mathbb{N}_+$, and let σ^2 denote the (finite) variance of X . Suppose that $n \in \mathbb{N}_+$ and that (X_1, X_2, \dots, X_n) is a sequence of independent variables, each with the distribution of X . Then $X_1 + X_2 + \dots + X_n$ has the same distribution as $a_n + b_n X$. Taking variances gives $n\sigma^2 = b_n^2 \sigma^2$ and hence $b_n = \sqrt{n}$. Taking expected values now gives $n\mu = a_n + \sqrt{n}\mu$.

It will turn out that the only stable distribution with finite variance is the normal distribution, but the result above is useful as an intermediate step. Next, it seems fairly clear from the definition that the family of stable distributions is itself a location-scale family.

Suppose that the distribution of X is stable, with centering parameters $a_n \in \mathbb{R}$ and norming parameters $b_n \in (0, \infty)$ for $n \in \mathbb{N}_+$. If $c \in \mathbb{R}$ and $d \in (0, \infty)$, then the distribution of $Y = c + dX$ is also stable, with centering parameters $da_n + (n - b_n)c$ and norming parameters b_n for $n \in \mathbb{N}_+$.

Proof

Suppose that $n \in \mathbb{N}_+$ and that (Y_1, Y_2, \dots, Y_n) is a sequence of independent variables, each with the same distribution as Y . Then $Y_1 + Y_2 + \dots + Y_n$ has the same distribution as $nc + d(X_1 + X_2 + \dots + X_n)$ where (X_1, X_2, \dots) is a sequence of independent variables, each with the same distribution as X . By stability, $X_1 + X_2 + \dots + X_n$ has the same distribution as $a_n + b_n X$. Hence $Y_1 + Y_2 + \dots + Y_n$ has the same distribution as $(nc + da_n) + db_n X$, which in turn has the same distribution as $[da_n + (n - b_n)c] + b_n Y$.

An important point is the the norming parameters are unchanged under a location-scale transformation.

Suppose that the distribution of X is stable, with centering parameters $a_n \in \mathbb{R}$ and norming parameters $b_n \in (0, \infty)$ for $n \in \mathbb{N}_+$. Then the distribution of $-X$ is stable, with centering parameters $-a_n$ and norming parameters b_n for $n \in \mathbb{N}_+$.

Proof

If $n \in \mathbb{N}_+$ and (X_1, X_2, \dots, X_n) is a sequence of independent variables, each with the same distribution as X then $(-X_1, -X_2, \dots, -X_n)$ is a sequence of independent variables each with the same distribution as $-X$. By stability, $-\sum_{i=1}^n X_i$ has the same distribution as $-(a_n + b_n X) = -a_n + b_n(-X)$.

From the last two results, if X has a stable distribution, then so does $c + dX$, with the same norming parameters, for every $c, d \in \mathbb{R}$ with $d \neq 0$. Stable distributions are also closed under convolution (corresponding to sums of independent variables) if the norming parameters are the same.

Suppose that X and Y are independent variables. Assume also that X has a stable distribution with centering parameters $a_n \in \mathbb{R}$ and norming parameters $b_n \in (0, \infty)$ for $n \in \mathbb{N}_+$, and that Y has a stable distribution with centering parameters $c_n \in \mathbb{R}$ and the same norming parameters b_n for $n \in \mathbb{N}_+$. Then $Z = X + Y$ has a stable distribution with centering parameters $a_n + c_n$ and norming parameters b_n for $n \in \mathbb{N}_+$.

Proof

Suppose that $n \in \mathbb{N}_+$ and that (Z_1, X_2, \dots, Z_n) is a sequence of independent variables, each with the same distribution as Z . Then $\sum_{i=1}^n Z_i$ has the same distribution as $\sum_{i=1}^n X_i + \sum_{i=1}^n Y_i$ where $\mathbf{X} = (X_1, X_2, \dots, X_n)$ is a sequence of independent variables, each with the same distribution as X , and $\mathbf{Y} = (Y_1, Y_2, \dots, Y_n)$ is a sequence of independent variables, each with the same distribution as Y , and where \mathbf{X} and \mathbf{Y} are independent. By stability, this is the same as the distribution of $(a_n + b_n X) + (c_n + b_n Y) = (a_n + c_n) + b_n(X + Y)$.

We can now give another characterization of stability that just involves two independent copies of X .

Random variable X has a stable distribution if and only if the following condition holds: If X_1, X_2 are independent variables, each with the same distribution as X and $d_1, d_2 \in (0, \infty)$ then $d_1 X_1 + d_2 X_2$ has the same distribution as $a + bX$ for some $a \in \mathbb{R}$ and $b \in (0, \infty)$.

Proof

Suppose that the condition in the theorem holds. We will show by induction that the condition in the [definition](#) holds. For $n = 2$, the stability condition is a special case of the condition in the theorem, with $d_1 = d_2 = 1$. Suppose that the stability condition holds for a given $n \in \mathbb{N}_+$. Suppose that $(X_1, X_2, \dots, X_n, X_{n+1})$ is a sequence of independent random variables, each with the distribution of X . By the induction hypothesis, $Y_n = X_1 + X_2 + \dots + X_n$ has the same distribution as $a_n + b_n X$ for some $a_n \in \mathbb{R}$ and $b_n \in (0, \infty)$. By independence, $Y_{n+1} = X_1 + X_2 + \dots + X_n + X_{n+1}$ has the same distribution as $a_n + b_n X_1 + X_{n+1}$. By another application of the condition above, $b_n X_1 + X_{n+1}$ has the same distribution as $c + b_{n+1} X$ for some $c \in \mathbb{R}$ and $b_{n+1} \in (0, \infty)$. But then Y_{n+1} has the same distribution as $(a_n + c) + b_{n+1} X$.

As a corollary of a couple of the results above, we have the following:

Suppose that X and Y are independent with the same stable distribution. Then the distribution of $X - Y$ is strictly stable, with the same norming parameters.

Note that the distribution of $X - Y$ is symmetric (about 0). The last result is useful because it allows us to get rid of the centering parameters when proving facts about the norming parameters. Here is the most important of those facts:

Suppose that X has a stable distribution. Then the norming parameters have the form $b_n = n^{1/\alpha}$ for $n \in \mathbb{N}_+$, for some $\alpha \in (0, 2]$. The parameter α is known as the *index* or *characteristic exponent* of the distribution.

Proof

The proof is in several steps, and is based on the proof in [An Introduction to Probability Theory and Its Applications](#), Volume II, by William Feller. The proof uses the basic trick of writing a sum of independent copies of X in different ways in order to obtain relationships between the norming constants b_n .

First we can assume from our last result that the distribution of X is symmetric and strictly stable. Let (X_1, X_2, \dots) be a sequence of independent variables, each with the distribution of X . Let $Y_n = \sum_{i=1}^n X_i$ for $n \in \mathbb{N}_+$. Now let $n, m \in \mathbb{N}_+$ and consider Y_{mn} . Directly from stability, Y_{mn} has the same distribution as $b_{mn}X$. On the other hand, Y_{mn} can be thought of as a sum of m “blocks”, where each block is a sum of n independent copies of X . Each block has the same distribution as b_nX , and since the blocks are independent, it follows that Y_{mn} has the same distribution as

$$b_nX_1 + b_nX_2 + \dots + b_nX_m = b_n(X_1 + X_2 + \dots + X_m) \quad (5.3.1)$$

But by another application of stability, the random variable on the right has the same distribution as b_nb_mX . It then follows that $b_{mn} = b_nb_m$ for all $m, n \in \mathbb{N}_+$ which in turn leads to $b_{n^k} = b_n^k$ for all $n, k \in \mathbb{N}_+$.

We use the same trick again, this time with a sum. Let $m, n \in \mathbb{N}_+$ and consider Y_{m+n} . Directly from stability, Y_{m+n} has the same distribution as $b_{m+n}X$. On the other hand, Y_{m+n} can be thought of as the sum of two blocks. The first is the sum of m independent copies of X and hence has the same distribution as b_mX , while the second is the sum of n independent copies of X and hence has the same distribution as b_nX . Since the blocks are independent, it follows that $b_{m+n}X$ has the same distribution as $b_mX_1 + b_nX_2$, or equivalently, X has the same distribution as

$$U = \frac{b_m}{b_{m+n}}X_1 + \frac{b_n}{b_{m+n}}X_2 \quad (5.3.2)$$

Next note that for $x > 0$,

$$\left\{ X_1 \geq 0, X_2 > \frac{b_{m+n}}{b_n}x \right\} \subseteq \{U > x\} \quad (5.3.3)$$

and so by independence,

$$\mathbb{P}(U > x) \geq \mathbb{P}\left(X_1 \geq 0, X_2 > \frac{b_{m+n}}{b_n}x\right) = \mathbb{P}(X_1 \geq 0)\mathbb{P}\left(X_2 > \frac{b_{m+n}}{b_n}x\right) \quad (5.3.4)$$

But by symmetry, $\mathbb{P}(X_1 \geq 0) \geq \frac{1}{2}$. Also X_2 and U have the same distribution as X , so we conclude that

$$\mathbb{P}(X > x) \geq \frac{1}{2}\mathbb{P}\left(X > \frac{b_{m+n}}{b_n}x\right), \quad x > 0 \quad (5.3.5)$$

It follows that the ratios b_n/b_{m+n} are bounded for $m, n \in \mathbb{N}_+$. If that were not the case, we could find a sequence of integers m, n with $b_{m+n}/b_n \rightarrow 0$, in which case the displayed equation above would give the contradiction $\mathbb{P}(X > x) \geq \frac{1}{4}$ for all $x > 0$. Restating, the ratios b_k/b_n are bounded for $k, n \in \mathbb{N}_+$ with $k < n$.

Fix $r \in \mathbb{N}_+$. There exists a unique $\alpha \in (0, \infty)$ with $b_r = r^{1/\alpha}$. It then follows from step 1 above that $b_n = n^{1/\alpha}$ for every $n = r^j$ with $j \in \mathbb{N}_+$. Similarly, if $s \in \mathbb{N}_+$, there exists $\beta \in (0, \infty)$ with $b_s = s^{1/\beta}$ and then $b_m = m^{1/\beta}$ for every $m = s^k$ with $k \in \mathbb{N}_+$. For our next step, we show that $\alpha = \beta$ and it then follows that $b_n = n^{1/\alpha}$ for every $n \in \mathbb{N}_+$. Towards that end, note that if $m = s^k$ with $k \in \mathbb{N}_+$ there exists $n = r^j$ with $j \in \mathbb{N}_+$ with $n \leq m \leq rn$. Hence

$$b_m = m^{1/\beta} \leq (rn)^{1/\beta} = r^{1/\beta}b_n^{\alpha/\beta} \quad (5.3.6)$$

Therefore

$$\frac{b_m}{b_n} \leq r^{1/\beta}b_n^{\alpha/\beta-1} \quad (5.3.7)$$

Since the coefficients b_n are unbounded in $n \in \mathbb{N}_+$, but the ratios b_n/b_m are bounded for $m, n \in \mathbb{N}_+$ with $m > n$, the last inequality implies that $\beta \leq \alpha$. Reversing the roles of m and n then gives $\alpha \leq \beta$ and hence $\alpha = \beta$.

All that remains to show is that $\alpha \leq 2$. We will do this by showing that if $\alpha > 2$, then X must have finite variance, in which case the [finite variance property](#) above leads to the contradiction $\alpha = 2$. Since X^2 is nonnegative,

$$\mathbb{E}(X^2) = \int_0^\infty \mathbb{P}(X^2 > x) dx = \int_0^\infty \mathbb{P}(|X| > \sqrt{x}) dx = \sum_{k=1}^\infty \int_{2^{k-1}}^{2^k} \mathbb{P}(|X| > \sqrt{x}) dx \quad (5.3.8)$$

So the idea is to find bounds on the integrals on the right so that the sum converges. Towards that end, note that for $t > 0$ and $n \in \mathbb{N}_+$

$$\mathbb{P}(|Y_n| > tb_n) = \mathbb{P}(b_n |X| > tb_n) = \mathbb{P}(|X| > t) \quad (5.3.9)$$

Hence we can choose t so that $\mathbb{P}(|Y_n| > tb_n) \leq \frac{1}{4}$. On the other hand, using a special inequality for symmetric distributions,

$$\frac{1}{2}(1 - \exp[-n\mathbb{P}(|X| > tb_n)]) \leq \mathbb{P}(|Y_n| > tb_n) \quad (5.3.10)$$

This implies that $n\mathbb{P}(|X| > tb_n)$ is bounded in n or otherwise the two inequalities together would lead to $\frac{1}{2} \leq \frac{1}{4}$. Substituting $x = tb_n = tn^{1/\alpha}$ leads to $\mathbb{P}(|X| > x) \leq Mx^{-\alpha}$ for some $M > 0$. It then follows that

$$\int_{2^{k-1}}^{2^k} \mathbb{P}(|X| > \sqrt{x}) dx \leq M2^{k(1-\alpha/2)} \quad (5.3.11)$$

If $\alpha > 2$, the series with the terms on the right converges and we have $\mathbb{E}(X^2) < \infty$.

Every stable distribution is continuous.

Proof

As in the proof of the previous theorem, suppose that X has a symmetric stable distribution with norming parameters b_n for $n \in \mathbb{N}_+$. As a special case of the last proof, for $n \in \mathbb{N}_+$, X has the same distribution as

$$\frac{1}{b_{n+1}}X_1 + \frac{b_n}{b_{n+1}}X_2 \quad (5.3.12)$$

where X_1 and X_2 are independent and also have this distribution. Suppose now that $\mathbb{P}(X = x) = p$ for some $x \neq 0$ where $p > 0$. Then

$$\mathbb{P}\left(X = \frac{1+b_n}{b_{1+n}}x\right) \geq \mathbb{P}(X_1 = x)\mathbb{P}(X_2 = x) = p^2 > 0 \quad (5.3.13)$$

If the index $\alpha \neq 1$, the points

$$\frac{(1+b_n)}{b_{1+n}}x = \frac{1+n^{1/\alpha}}{(1+n)^{1/\alpha}}x, \quad n \in \mathbb{N}_+ \quad (5.3.14)$$

are distinct, which gives us infinitely many atoms, each with probability at least p^2 —clearly a contradiction.

Next, suppose that the only atom is $x = 0$ and that $\mathbb{P}(X = 0) = p$ where $p \in (0, 1)$. Then $X_1 + X_2$ has the same distribution as b_2X . But $\mathbb{P}(X_1 + X_2 = 0) = \mathbb{P}(X_1 = 0)\mathbb{P}(X_2 = 0) = p^2$ while $\mathbb{P}(b_2X = 0) = \mathbb{P}(X = 0) = p$, another contradiction.

The next result is a precise statement of the limit theorem alluded to in the introductory paragraph.

Suppose that (X_1, X_2, \dots) is a sequence of independent, identically distributed random variables, and let $Y_n = \sum_{i=1}^n X_i$ for $n \in \mathbb{N}_+$. If there exist constants $a_n \in \mathbb{R}$ and $b_n \in (0, \infty)$ for $n \in \mathbb{N}_+$ such that $(Y_n - a_n)/b_n$ has a (non-degenerate) limiting distribution as $n \rightarrow \infty$, then the limiting distribution is stable.

The following theorem completely characterizes stable distributions in terms of the characteristic function.

Suppose that X has a stable distribution. The characteristic function of X has the following form, for some $\alpha \in (0, 2]$, $\beta \in [-1, 1]$, $c \in \mathbb{R}$, and $d \in (0, \infty)$

$$\chi(t) = \mathbb{E}(e^{itX}) = \exp(itc - d^\alpha |t|^\alpha [1 + i\beta \operatorname{sgn}(t)u_\alpha(t)]), \quad t \in \mathbb{R} \quad (5.3.15)$$

where sgn is the usual sign function, and where

$$u_\alpha(t) = \begin{cases} \tan(\frac{\pi\alpha}{2}), & \alpha \neq 1 \\ \frac{2}{\pi} \ln(|t|), & \alpha = 1 \end{cases} \quad (5.3.16)$$

1. The parameter α is the *index*, as before.
2. The parameter β is the *skewness parameter*.
3. The parameter c is the *location parameter*.
4. The parameter d is the *scale parameter*.

Thus, the family of stable distributions is a 4 parameter family. The index parameter α and the skewness parameter β can be considered *shape parameters*. When the location parameter $c = 0$ and the scale parameter $d = 1$, we get the *standard form* of the stable distributions, with characteristic function

$$\chi(t) = \mathbb{E}(e^{itX}) = \exp(-|t|^\alpha [1 + i\beta \operatorname{sgn}(t)u_\alpha(t)]), \quad t \in \mathbb{R} \quad (5.3.17)$$

The characteristic function gives another proof that stable distributions are closed under convolution (corresponding to sums of independent variables), if the index is fixed.

Suppose that X_1 and X_2 are independent random variables, and that X_1 and X_2 have the stable distribution with common index $\alpha \in (0, 2]$, skewness parameter $\beta_k \in [-1, 1]$, location parameter $c_k \in \mathbb{R}$, and scale parameter $d_k \in (0, \infty)$. Then $X_1 + X_2$ has the stable distribution with index α , location parameter $c = c_1 + c_2$, scale parameter $d = (d_1^\alpha + d_2^\alpha)^{1/\alpha}$, and skewness parameter

$$\beta = \frac{\beta_1 d_1^\alpha + \beta_2 d_2^\alpha}{d_1^\alpha + d_2^\alpha} \quad (5.3.18)$$

Proof

Let χ_k denote the characteristic function of X_k for $k \in \{1, 2\}$. Then $X_1 + X_2$ has characteristic function $\chi = \chi_1 \chi_2$. The result follows from using the form of the characteristic function [above](#) and some algebra.

Special Cases

Three special parametric families of distributions studied in this chapter are stable. In the proofs in this subsection, we use the definition of stability and various important properties of the distributions. These properties, in turn, are verified in the sections devoted to the distributions. We also give proofs based on the characteristic function, which allows us to identify the skewness parameter.

The normal distribution is stable with index $\alpha = 2$. There is no skewness parameter.

Proof

If $n \in \mathbb{N}_+$ and (Z_1, Z_2, \dots, Z_n) is a sequence of independent variables, each with the standard normal distribution, then $Z_1 + Z_2 + \dots + Z_n$ has the normal distribution with mean 0 and variance n . But this is also the distribution of $\sqrt{n}Z$ where Z has the standard normal distribution. Hence the standard normal distribution is strictly stable, with index $\alpha = 2$. The normal distribution with mean $\mu \in \mathbb{R}$ and standard deviation $\sigma \in (0, \infty)$ is the distribution of $\mu + \sigma Z$. From our basic properties above, this distribution is stable with index $\alpha = 2$ and centering parameters $(n - \sqrt{n})\mu$ for $n \in \mathbb{N}$.

In terms of the characteristic function, note that if $\alpha = 2$ then $u_\alpha(t) = \tan(\pi) = 0$ so the skewness parameter β drops out completely. The characteristic function in standard form $\chi(t) = e^{-t^2}$ for $t \in \mathbb{R}$, which is the characteristic function of the normal distribution with mean 0 and variance 2.

Of course, the normal distribution has finite variance, so once we know that it is stable, it follows from the [finite variance property](#) above that the index must be 2. Moreover, the characteristic function shows that the normal distribution is the only stable distribution with index 2, and hence the only stable distribution with finite variance.

Open the special distribution simulator and select the normal distribution. Vary the parameters and note the shape and location of the probability density function. For various values of the parameters, run the simulation 1000 times and compare the empirical density function to the probability density function.

The Cauchy distribution is stable with index $\alpha = 1$ and skewness parameter $\beta = 0$.

Proof

If $n \in \mathbb{N}_+$ and (Z_1, Z_2, \dots, Z_n) is a sequence of independent variables, each with the standard Cauchy distribution, then $Z_1 + Z_2 + \dots + Z_n$ has the Cauchy distribution scale parameter n . By definition this is the same as the distribution of nZ where Z has the standard Cauchy distribution. Hence the standard Cauchy distribution is strictly stable, with index $\alpha = 1$. The Cauchy distribution with location parameter $a \in \mathbb{R}$ and scale parameter $b \in (0, \infty)$ is the distribution of $a + bZ$. From our basic properties above, this distribution is strictly stable with index $\alpha = 1$.

When $\alpha = 1$ and $\beta = 0$ the characteristic function in standard form is $\chi(t) = \exp(-|t|)$ for $t \in \mathbb{R}$, which is the characteristic function of the standard Cauchy distribution.

Open the special distribution simulator and select the Cauchy distribution. Vary the parameters and note the shape and location of the probability density function. For various values of the parameters, run the simulation 1000 times and compare the empirical density function to the probability density function.

The Lévy distribution is stable with index $\alpha = \frac{1}{2}$ and skewness parameter $\beta = 1$.

Proof

If $n \in \mathbb{N}_+$ and (Z_1, Z_2, \dots, Z_n) is a sequence of independent variables, each with the standard Lévy distribution, then $Z_1 + Z_2 + \dots + Z_n$ has the Lévy distribution scale parameter n^2 . By definition this is the same as the distribution of n^2Z where Z has the standard Lévy distribution. Hence the standard Lévy distribution is strictly stable, with index $\alpha = \frac{1}{2}$. The Lévy distribution with location parameter $a \in \mathbb{R}$ and scale parameter $b \in (0, \infty)$ is the distribution of $a + bZ$. From our basic properties above, this distribution is stable with index $\alpha = \frac{1}{2}$ and centering parameters $(n - n^2)a$ for $n \in \mathbb{N}_+$.

When $\alpha = \frac{1}{2}$ note that $u_\alpha(t) = \tan\left(\frac{\pi}{4}\right) = 1$. So the characteristic function in standard form with $\alpha = \frac{1}{2}$ and $\beta = 1$ is

$$\chi(t) = \exp\left(-|t|^{1/2} [1 + i \operatorname{sgn}(t)]\right) \quad (5.3.19)$$

which is the characteristic function of the standard Lévy distribution.

Open the special distribution simulator and select the Lévy distribution. Vary the parameters and note the shape and location of the probability density function. For various values of the parameters, run the simulation 1000 times and compare the empirical density function to the probability density function.

The normal, Cauchy, and Lévy distributions are the only stable distributions for which the probability density function is known in closed form.

This page titled [5.3: Stable Distributions](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist \(Random Services\)](#) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

5.4: Infinitely Divisible Distributions

This section discusses a theoretical topic that you may want to skip if you are a new student of probability.

Basic Theory

Infinitely divisible distributions form an important class of distributions on \mathbb{R} that includes the stable distributions, the compound Poisson distributions, as well as several of the most important special parametric families of distributions. Basically, the distribution of a real-valued random variable is infinitely divisible if for each $n \in \mathbb{N}_+$, the variable can be decomposed into the sum of n independent copies of another variable. Here is the precise definition.

The distribution of a real-valued random variable X is *infinitely divisible* if for every $n \in \mathbb{N}_+$, there exists a sequence of independent, identically distributed variables (X_1, X_2, \dots, X_n) such that $X_1 + X_2 + \dots + X_n$ has the same distribution as X .

If the distribution of X is stable then the distribution is infinitely divisible.

Proof

Let $n \in \mathbb{N}_+$ and let (X_1, X_2, \dots, X_n) be a sequence of independent variables, each with the same distribution as X . By the definition of stability, there exists $a_n \in \mathbb{R}$ and $b_n \in (0, \infty)$ such that $\sum_{i=1}^n X_i$ has the same distribution as $a_n + b_n X$. But then

$$\frac{1}{b_n} \left(\sum_{i=1}^n X_i - a_n \right) = \sum_{i=1}^n \frac{X_i - a_n/n}{b_n} \quad (5.4.1)$$

has the same distribution as X . But $\left(\frac{X_i - a_n/n}{b_n} : i \in \{1, 2, \dots, n\} \right)$ is an IID sequence, and hence the distribution of X is infinitely divisible.

Suppose now that $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of independent, identically distributed random variables, and that N has a Poisson distribution and is independent of \mathbf{X} . Recall that the distribution of $\sum_{i=1}^N X_i$ is said to be compound Poisson. Like the stable distributions, the compound Poisson distributions form another important class of infinitely divisible distributions.

Suppose that Y is a random variable.

1. If Y is compound Poisson then Y is infinitely divisible.
2. If Y is infinitely divisible and takes values in \mathbb{N} then Y is compound Poisson.

Proof

1. Suppose that Y is compound Poisson, so that we can take $Y = \sum_{i=1}^N X_i$ where $\mathbf{X} = (X_1, X_2, \dots)$ is a sequence of independent, identically distributed random variables with common characteristic function ϕ , and where N is independent of \mathbf{X} and has the Poisson distribution with parameter $\lambda \in (0, \infty)$. The characteristic function χ of Y is given by $\chi(t) = \exp(\lambda[\phi(t) - 1])$ for $t \in \mathbb{R}$. But then for $n \in \mathbb{N}_+$,

$$\chi(t) = \left[\exp\left(\frac{\lambda}{n}[\phi(t) - 1]\right) \right]^n, \quad t \in \mathbb{R} \quad (5.4.2)$$

But $t \mapsto \exp\left(\frac{\lambda}{n}[\phi(t) - 1]\right)$ is the characteristic function of the compound Poisson distribution corresponding to \mathbf{X} but with Poisson parameter λ/n . Restated in terms of random variables, $Y = \sum_{i=1}^n Y_i$ where Y_i has the compound Poisson distribution corresponding to \mathbf{X} with Poisson parameter λ/n .

2. The proof is from [An Introduction to Probability Theory and Its Applications](#) by William Feller, and requires some additional notation. Recall that the symbol \asymp is used to connect functions that are *asymptotically the same* in the sense that the ratio converges to 1. Suppose now that Y takes values in \mathbb{N} and is infinitely divisible. In this case we can use probability generating functions rather than characteristic functions, so let P denote the PGF of Y . By definition, $P(t) = \sum_{k=0}^{\infty} p_k t^k$ where $p_k = \mathbb{P}(Y = k)$ for $k \in \mathbb{N}$. Since Y is infinitely divisible, $P^{1/n}$ is also a PGF for every

$n \in \mathbb{N}_+$, so let $P^{1/n}(t) = \sum_{k=0}^{\infty} p_{nk} t^k$ where $p_{nk} \geq 0$ for $k \in \mathbb{N}$ and $n \in \mathbb{N}_+$ and $\sum_{k=0}^{\infty} p_{nk} = 1$ for $n \in \mathbb{N}_+$. As with all PGFs, the series for $P(t)$ and for $P^{1/n}(t)$ converge at least for $t \in [0, 1]$, and this interval is sufficient for a PGF to completely determine the underlyingly distribution. For $n \in \mathbb{N}_+$, we have

$$\sum_{k=0}^{\infty} p_k t^k = \left(\sum_{k=0}^{\infty} p_{nk} t^k \right)^n \quad (5.4.3)$$

Expanding the series on the right and then equating coefficients of the two series term by term, we see that if $p_0 = 0$ then $p_{n0} = 0$ which in turn would imply $p_1 = \dots = p_{n-1} = 0$. Since this is true for all $n \in \mathbb{N}_+$, we would have P identically 0, which is a contradiction. Hence $p_0 > 0$ and so $P(t) > 0$ for $t \in [0, 1]$ and therefore $[P(t)/p_0]^{1/n} \rightarrow 1$ as $n \rightarrow \infty$ for $t \in [0, 1]$. Next recall that $\ln(1+x) \asymp x$ as $x \downarrow 0$. It follows that for $t \in [0, 1]$,

$$\ln \left(\left[\frac{P(t)}{p_0} \right]^{1/n} \right) = \ln \left\{ 1 + \left(\left[\frac{P(t)}{p_0} \right]^{1/n} - 1 \right) \right\} \asymp \left[\frac{P(t)}{p_0} \right]^{1/n} - 1 \text{ as } n \rightarrow \infty \quad (5.4.4)$$

As a special case, when $t = 1$, we have $\ln \left[(1/p_0)^{1/n} \right] \asymp (1/p_0)^{1/n} - 1$ as $n \rightarrow \infty$. Hence using properties of logarithms and a bit of algebra,

$$\frac{\ln[P(t)] - \ln(p_0)}{-\ln(p_0)} = \frac{\ln \left([P(t)/p_0]^{1/n} \right)}{\ln \left[(1/p_0)^{1/n} \right]} \asymp \frac{P^{1/n}(t) - p_0^{1/n}}{1 - p_0^{1/n}} \text{ as } n \rightarrow \infty \quad (5.4.5)$$

The power series (about 0) for the expression on the right has positive coefficients, and the expression takes the value 1 when $t = 1$. Thus, the expression on the right is a PGF for each $n \in \mathbb{N}_+$. By the continuity theorem for convergence in distribution, it follows that the left side, which we will denote by $Q(t)$, is also a PGF. Solving we have

$$P(t) = \exp(\lambda[Q(t) - 1]), \quad t \in [0, 1] \quad (5.4.6)$$

where $\lambda = -\ln(p_0)$. This is the PGF of the distribution obtained by compounding the distribution with PGF Q with the Poisson distribution with parameter λ .

Special Cases

A number of special distributions are infinitely divisible. Proofs of the results stated below are given in the individual sections.

Stable Distributions

First, the normal distribution, the Cauchy distribution, and the Lévy distribution are stable, so they are infinitely divisible. However, direct arguments give more information, because we can identify the distribution of the component variables.

The normal distribution is infinitely divisible. If X has the normal distribution with mean $\mu \in \mathbb{R}$ and standard deviation $\sigma \in (0, \infty)$, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \dots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and X_i has the normal distribution with mean μ/n and standard deviation σ/\sqrt{n} for each $i \in \{1, 2, \dots, n\}$.

The Cauchy distribution is infinitely divisible. If X has the Cauchy distribution with location parameter $a \in \mathbb{R}$ and scale parameter $b \in (0, \infty)$, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \dots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and X_i has the Cauchy distribution with location parameter a/n and scale parameter b/n for each $i \in \{1, 2, \dots, n\}$.

Other Special Distributions

On the other hand, there are distributions that are infinitely divisible but not stable.

The gamma distribution is infinitely divisible. If X has the gamma distribution with shape parameter $k \in (0, \infty)$ and scale parameter $b \in (0, \infty)$, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \dots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and X_i has the gamma distribution with shape parameter k/n and scale parameter b for each $i \in \{1, 2, \dots, n\}$.

The chi-square distribution is infinitely divisible. If X has the chi-square distribution with $k \in (0, \infty)$ degrees of freedom, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \cdots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and X_i has the chi-square distribution with k/n degrees of freedom for each $i \in \{1, 2, \dots, n\}$.

The Poisson distribution is infinitely divisible. If X has the Poisson distribution with rate parameter $\lambda \in (0, \infty)$, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \cdots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and X_i has the Poisson distribution with rate parameter λ/n for each $i \in \{1, 2, \dots, n\}$.

The general negative binomial distribution on \mathbb{N} is infinitely divisible. If X has the negative binomial distribution on \mathbb{N} with parameters $k \in (0, \infty)$ and $p \in (0, 1)$, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \cdots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and X_i has the negative binomial distribution on \mathbb{N} with parameters k/n and p for each $i \in \{1, 2, \dots, n\}$.

Since the Poisson distribution and the negative binomial distributions are distributions on \mathbb{N} , it follows from the [characterization above](#) that these distributions must be compound Poisson. Of course it is completely trivial that the Poisson distribution is compound Poisson, but it's far from obvious that the negative binomial distribution has this property. It turns out that the negative binomial distribution can be obtained by compounding the logarithmic series distribution with the Poisson distribution.

The Wald distribution is infinitely divisible. If X has the Wald distribution with shape parameter $\lambda \in (0, \infty)$ and mean $\mu \in (0, \infty)$, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \cdots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and X_i has the Wald distribution with shape parameter λ/n^2 and mean μ/n for each $i \in \{1, 2, \dots, n\}$.

This page titled [5.4: Infinitely Divisible Distributions](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist \(Random Services\)](#) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

5.5: Power Series Distributions

Power Series Distributions are discrete distributions on (a subset of) \mathbb{N} constructed from power series. This class of distributions is important because most of the special, discrete distributions are power series distributions.

Basic Theory

Power Series

Suppose that $\mathbf{a} = (a_0, a_1, a_2, \dots)$ is a sequence of nonnegative real numbers. We are interested in the power series with \mathbf{a} as the sequence of coefficients. Recall first that the *partial sum* of order $n \in \mathbb{N}$ is

$$g_n(\theta) = \sum_{k=0}^n a_k \theta^k, \quad \theta \in \mathbb{R} \quad (5.5.1)$$

The *power series* g is then defined by $g(\theta) = \lim_{n \rightarrow \infty} g_n(\theta)$ for $\theta \in \mathbb{R}$ for which the limit exists, and is denoted

$$g(\theta) = \sum_{n=0}^{\infty} a_n \theta^n \quad (5.5.2)$$

Note that the series converges when $\theta = 0$, and $g(0) = a_0$. Beyond this trivial case, recall that there exists $r \in [0, \infty]$ such that the series converges absolutely for $|\theta| < r$ and diverges for $|\theta| > r$. The number r is the *radius of convergence*. From now on, we assume that $r > 0$. If $r < \infty$, the series may converge (absolutely) or may diverge to ∞ at the endpoint r . At $-r$, the series may converge absolutely, may converge conditionally, or may diverge.

Distributions

From now on, we restrict θ to the interval $[0, r)$; this interval is our *parameter space*. Some of the results below may hold when $r < \infty$ and $\theta = r$, but dealing with this case explicitly makes the exposition unnecessarily cumbersome.

Suppose that N is a random variable with values in \mathbb{N} . Then N has the *power series distribution* associated with the function g (or equivalently with the sequence \mathbf{a}) and with parameter $\theta \in [0, r)$ if N has probability density function f_θ given by

$$f_\theta(n) = \frac{a_n \theta^n}{g(\theta)}, \quad n \in \mathbb{N} \quad (5.5.3)$$

Proof

To show that f_θ is a valid discrete probability density function, note that $a_n \theta^n$ is nonnegative for each $n \in \mathbb{N}$ and $g(\theta)$, by definition, is the normalizing constant for the sequence $(a_n \theta^n : n \in \mathbb{N})$.

Note that when $\theta = 0$, the distribution is simply the point mass distribution at 0; that is, $f_0(0) = 1$.

The distribution function F_θ is given by

$$F_\theta(n) = \frac{g_n(\theta)}{g(\theta)}, \quad n \in \mathbb{N} \quad (5.5.4)$$

Proof

This follows immediately from the definitions since $F_\theta(n) = \sum_{k=0}^n f_\theta(k)$ for $n \in \mathbb{N}$

Of course, the probability density function f_θ is most useful when the power series $g(\theta)$ can be given in closed form, and similarly the distribution function F_θ is most useful when the power series and the partial sums can be given in closed form

Moments

The moments of N can be expressed in terms of the underlying power series function g , and the nicest expression is for the factorial moments. Recall that the permutation formula is $t^{(k)} = t(t-1) \cdots (t-k+1)$ for $t \in \mathbb{R}$ and $k \in \mathbb{N}$, and the *factorial moment* of N of order $k \in \mathbb{N}$ is $\mathbb{E}(N^{(k)})$.

For $\theta \in [0, r)$, the factorial moments of N are as follows, where $g^{(k)}$ is the k th derivative of g .

$$\mathbb{E}(N^{(k)}) = \frac{\theta^k g^{(k)}(\theta)}{g(\theta)}, \quad k \in \mathbb{N} \quad (5.5.5)$$

Proof

Recall that a power series is infinitely differentiable in the open interval of convergence, and that the derivatives can be taken term by term. Thus

$$\mathbb{E}(N^{(k)}) = \sum_{n=0}^{\infty} n^{(k)} \frac{a_n \theta^n}{g(\theta)} = \frac{\theta^k}{g(\theta)} \sum_{n=k}^{\infty} a_n n^{(k)} \theta^{n-k} = \frac{\theta^k}{g(\theta)} g^{(k)}(\theta) \quad (5.5.6)$$

The mean and variance of N are

1. $\mathbb{E}(N) = \theta g'(\theta) / g(\theta)$
2. $\text{var}(N) = \theta^2 (g''(\theta) / g(\theta) - [g'(\theta) / g(\theta)]^2)$

Proof

1. This follows from the previous result on factorial moments with $k = 1$.
2. This also follows from the previous result since $\text{var}(N) = \mathbb{E}(N^{(2)}) + \mathbb{E}(N)[1 - \mathbb{E}(N)]$.

The probability generating function of N also has a simple expression in terms of g .

For $\theta \in (0, r)$, the probability generating function P of N is given by

$$P(t) = \mathbb{E}(t^N) = \frac{g(\theta t)}{g(\theta)}, \quad t < \frac{r}{\theta} \quad (5.5.7)$$

Proof

For $t \in (0, r/\theta)$,

$$P(t) = \sum_{n=0}^{\infty} t^n f_{\theta}(n) = \frac{1}{g(\theta)} \sum_{n=0}^{\infty} a_n (t\theta)^n = \frac{g(t\theta)}{g(\theta)} \quad (5.5.8)$$

Relations

Power series distributions are closed with respect to sums of independent variables.

Suppose that N_1 and N_2 are independent, and have power series distributions relative to the functions g_1 and g_2 , respectively, each with parameter value $\theta < \min\{r_1, r_2\}$. Then $N_1 + N_2$ has the power series distribution relative to the function $g_1 g_2$, with parameter value θ .

Proof

A direct proof is possible, but there is an easy proof using probability generating functions. Recall that the PGF of the sum of independent variables is the product of the PGFs. Hence the PGF of $N_1 + N_2$ is

$$P(t) = P_1(t)P_2(t) = \frac{g_1(\theta t)}{g_1(\theta)} \frac{g_2(\theta t)}{g_2(\theta)} = \frac{g_1(\theta t)g_2(\theta t)}{g_1(\theta)g_2(\theta)}, \quad t < \min\left\{\frac{r_1}{\theta}, \frac{r_2}{\theta}\right\} \quad (5.5.9)$$

The last expression is the PGF of the power series distribution relative to the function $g_1 g_2$, at θ .

Here is a simple corollary.

Suppose that (N_1, N_2, \dots, N_k) is a sequence of independent variables, each with the same power series distribution, relative to the function g and with parameter value $\theta < r$. Then $N_1 + N_2 + \dots + N_k$ has the power series distribution relative to the function g^k and with parameter θ .

In the context of this result, recall that (N_1, N_2, \dots, N_k) is a *random sample* of size k from the common distribution.

Examples and Special Cases

Special Distributions

The Poisson distribution with rate parameter $\lambda \in [0, \infty)$ is a power series distribution relative to the function $g(\lambda) = e^\lambda$ for $\lambda \in [0, \infty)$.

Proof

This follows directly from the definition, since the PDF of the Poisson distribution with parameter λ is $f(n) = e^{-\lambda} \lambda^n / n!$ for $n \in \mathbb{N}$.

The geometric distribution on \mathbb{N} with success parameter $p \in (0, 1]$ is a power series distribution relative to the function $g(\theta) = 1/(1 - \theta)$ for $\theta \in [0, 1)$, where $\theta = 1 - p$.

Proof

This follows directly from the definition, since the PDF of the geometric distribution on \mathbb{N} is $f(n) = (1 - p)^n p = (1 - \theta)^n \theta$ for $n \in \mathbb{N}$.

For fixed $k \in (0, \infty)$, the negative binomial distribution on \mathbb{N} with stopping parameter k and success parameter $p \in (0, 1]$ is a power series distribution relative to the function $g(\theta) = 1/(1 - \theta)^k$ for $\theta \in [0, 1)$, where $\theta = 1 - p$.

Proof

This follows from the result above on [sums of IID variables](#), but can also be seen directly, since the PDF is

$$f(n) = \binom{n+k-1}{k-1} p^k (1-p)^n = (1-\theta)^k \binom{n+k-1}{k-1} \theta^n, \quad n \in \mathbb{N} \quad (5.5.10)$$

For fixed $n \in \mathbb{N}_+$, the binomial distribution with trial parameter n and success parameter $p \in [0, 1]$ is a power series distribution relative to the function $g(\theta) = (1 + \theta)^n$ for $\theta \in [0, \infty)$, where $\theta = p/(1 - p)$.

Proof

Note that the PDF of the binomial distribution is

$$f(k) = \binom{n}{k} p^k (1-p)^{n-k} = (1-p)^n \binom{n}{k} \left(\frac{p}{1-p} \right)^k = \frac{1}{(1+\theta)^n} \binom{n}{k} \theta^k, \quad k \in \{0, 1, \dots, n\} \quad (5.5.11)$$

where $\theta = p/(1 - p)$. This shows that the distribution is a power series distribution corresponding to the function $g(\theta) = (1 + \theta)^n$.

The logarithmic distribution with parameter $p \in (0, 1)$ is a power series distribution relative to the function $g(p) = -\ln(1 - p)$ for $p \in [0, 1)$.

Proof

This follows directly from the definition, since the PDF is

$$f(n) = \frac{1}{-\ln(1-p)} \frac{1}{n} p^n, \quad n \in \mathbb{N} \quad (5.5.12)$$

5.6: The Normal Distribution

The normal distribution holds an honored role in probability and statistics, mostly because of the central limit theorem, one of the fundamental theorems that forms a bridge between the two subjects. In addition, as we will see, the normal distribution has many nice mathematical properties. The normal distribution is also called the *Gaussian distribution*, in honor of Carl Friedrich Gauss, who was among the first to use the distribution.

The Standard Normal Distribution

Distribution Functions

The *standard normal distribution* is a continuous distribution on \mathbb{R} with probability density function ϕ given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}, \quad z \in \mathbb{R} \quad (5.6.1)$$

Proof that ϕ is a probability density function

Let $c = \int_{-\infty}^{\infty} e^{-z^2/2} dz$. We need to show that $c = \sqrt{2\pi}$. That is, $\sqrt{2\pi}$ is the normalizing constant for the function $z \mapsto e^{-z^2/2}$. The proof uses a nice trick:

$$c^2 = \int_{-\infty}^{\infty} e^{-x^2/2} dx \int_{-\infty}^{\infty} e^{-y^2/2} dy = \int_{\mathbb{R}^2} e^{-(x^2+y^2)/2} d(x, y) \quad (5.6.2)$$

We now convert the double integral to polar coordinates: $x = r \cos \theta$, $y = r \sin \theta$ where $r \in [0, \infty)$ and $\theta \in [0, 2\pi)$. So, $x^2 + y^2 = r^2$ and $d(x, y) = r d(r, \theta)$. Thus, converting back to iterated integrals,

$$c^2 = \int_0^{2\pi} \int_0^{\infty} r e^{-r^2/2} dr d\theta \quad (5.6.3)$$

Substituting $u = r^2/2$ in the inner integral gives $\int_0^{\infty} e^{-u} du = 1$ and then the outer integral is $\int_0^{2\pi} 1 d\theta = 2\pi$. Thus, $c^2 = 2\pi$ and so $c = \sqrt{2\pi}$.

The standard normal probability density function has the famous “bell shape” that is known to just about everyone.

The standard normal density function ϕ satisfies the following properties:

1. ϕ is symmetric about $z = 0$.
2. ϕ increases and then decreases, with mode $z = 0$.
3. ϕ is concave upward and then downward and then upward again, with inflection points at $z = \pm 1$.
4. $\phi(z) \rightarrow 0$ as $z \rightarrow \infty$ and as $z \rightarrow -\infty$.

Proof

These results follow from standard calculus. Note that $\phi'(z) = -z\phi(z)$ (which gives (b)) and hence also $\phi''(z) = (z^2 - 1)\phi(z)$ (which gives (c)).

In the Special Distribution Simulator, select the normal distribution and keep the default settings. Note the shape and location of the standard normal density function. Run the simulation 1000 times, and compare the empirical density function to the probability density function.

The standard normal distribution function Φ , given by

$$\Phi(z) = \int_{-\infty}^z \phi(t) dt = \int_{-\infty}^z \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt \quad (5.6.4)$$

and its inverse, the quantile function Φ^{-1} , cannot be expressed in closed form in terms of elementary functions. However approximate values of these functions can be obtained from the special distribution calculator, and from most mathematics and statistics software. Indeed these functions are so important that they are considered *special functions* of mathematics.

The standard normal distribution function Φ satisfies the following properties:

1. $\Phi(-z) = 1 - \Phi(z)$ for $z \in \mathbb{R}$
2. $\Phi^{-1}(p) = -\Phi^{-1}(1-p)$ for $p \in (0, 1)$
3. $\Phi(0) = \frac{1}{2}$, so the median is 0.

Proof

Part (a) follows from the symmetry of ϕ . Part (b) follows from part (a). Part (c) follows from part (a) with $z = 0$.

In the special distribution calculator, select the normal distribution and keep the default settings.

1. Note the shape of the density function and the distribution function.
2. Find the first and third quartiles.
3. Compute the interquartile range.

In the special distribution calculator, select the normal distribution and keep the default settings. Find the quantiles of the following orders for the standard normal distribution:

1. $p = 0.001, p = 0.999$
2. $p = 0.05, p = 0.95$
3. $p = 0.1, p = 0.9$

Moments

Suppose that random variable Z has the standard normal distribution.

The mean and variance of Z are

1. $\mathbb{E}(Z) = 0$
2. $\text{var}(Z) = 1$

Proof

1. Of course, by symmetry, if Z has a mean, the mean must be 0, but we have to argue that the mean exists. Actually it's not hard to compute the mean directly. Note that

$$\mathbb{E}(Z) = \int_{-\infty}^{\infty} z \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \int_{-\infty}^0 z \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz + \int_0^{\infty} z \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz \quad (5.6.5)$$

The integrals on the right can be evaluated explicitly using the simple substitution $u = z^2/2$. The result is $\mathbb{E}(Z) = -1/\sqrt{2\pi} + 1/\sqrt{2\pi} = 0$.

2. Note that

$$\text{var}(Z) = \mathbb{E}(Z^2) = \int_{-\infty}^{\infty} z^2 \phi(z) dz \quad (5.6.6)$$

Integrate by parts, using the parts $u = z$ and $dv = z\phi(z) dz$. Thus $du = dz$ and $v = -\phi(z)$. Note that $z\phi(z) \rightarrow 0$ as $z \rightarrow \infty$ and as $z \rightarrow -\infty$. Thus, the integration by parts formula gives $\text{var}(Z) = \int_{-\infty}^{\infty} \phi(z) dz = 1$.

- 3.

In the Special Distribution Simulator, select the normal distribution and keep the default settings. Note the shape and size of the mean \pm standard deviation bar. Run the simulation 1000 times, and compare the empirical mean and standard deviation to the true mean and standard deviation.

More generally, we can compute all of the moments. The key is the following recursion formula.

For $n \in \mathbb{N}_+$, $\mathbb{E}(Z^{n+1}) = n\mathbb{E}(Z^{n-1})$

Proof

First we use the differential equation in the proof of the [PDF properties](#) above, namely $\phi'(z) = -z\phi(z)$.

$$\mathbb{E}(Z^{n+1}) = \int_{-\infty}^{\infty} z^{n+1} \phi(z) dz = \int_{-\infty}^{\infty} z^n z \phi(z) dz = - \int_{-\infty}^{\infty} z^n \phi'(z) dz \quad (5.6.7)$$

Now we integrate by parts, with $u = z^n$ and $dv = \phi'(z) dz$ to get

$$\mathbb{E}(Z^{n+1}) = -z^n \phi(z) \Big|_{-\infty}^{\infty} + \int_{-\infty}^{\infty} n z^{n-1} \phi(z) dz = 0 + n \mathbb{E}(Z^{n-1}) \quad (5.6.8)$$

The moments of the standard normal distribution are now easy to compute.

For $n \in \mathbb{N}$,

1. $\mathbb{E}(Z^{2n}) = 1 \cdot 3 \cdots (2n-1) = (2n)! / (n! 2^n)$
2. $\mathbb{E}(Z^{2n+1}) = 0$

Proof

The result follows from the [mean and variance](#) and [recursion relation](#) above.

1. Since $\mathbb{E}(Z) = 0$ it follows that $\mathbb{E}(Z^n) = 0$ for every odd $n \in \mathbb{N}$.
2. Since $\mathbb{E}(Z^2) = 1$, it follows that $\mathbb{E}(Z^4) = 1 \cdot 3$ and then $\mathbb{E}(Z^6) = 1 \cdot 3 \cdot 5$, and so forth. You can use induction, if you like, for a more formal proof.

Of course, the fact that the odd-order moments are 0 also follows from the symmetry of the distribution. The following theorem gives the skewness and kurtosis of the standard normal distribution.

The skewness and kurtosis of Z are

1. $\text{skew}(Z) = 0$
2. $\text{kurt}(Z) = 3$

Proof

1. This follows immediately from the symmetry of the distribution. Directly, since Z has mean 0 and variance 1, $\text{skew}(Z) = \mathbb{E}(Z^3) = 0$.
2. Since $\mathbb{E}(Z) = 0$ and $\text{var}(Z) = 1$, $\text{kurt}(Z) = \mathbb{E}(Z^4) = 3$.

Because of the last result, (and the use of the standard normal distribution literally as a *standard*), the *excess kurtosis* of a random variable is defined to be the ordinary kurtosis minus 3. Thus, the excess kurtosis of the normal distribution is 0.

Many other important properties of the normal distribution are most easily obtained using the moment generating function or the characteristic function.

The moment generating function m and characteristic function χ of Z are given by

1. $m(t) = e^{t^2/2}$ for $t \in \mathbb{R}$.
2. $\chi(t) = e^{-t^2/2}$ for $t \in \mathbb{R}$.

Proof

1. Note that

$$m(t) = \mathbb{E}(e^{tZ}) = \int_{-\infty}^{\infty} e^{tz} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}z^2 + tz\right) dz \quad (5.6.9)$$

We complete the square in z to get $-\frac{1}{2}z^2 + tz = -\frac{1}{2}(z-t)^2 + \frac{1}{2}t^2$. Thus we have

$$\mathbb{E}(e^{tZ}) = e^{\frac{1}{2}t^2} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left[-\frac{1}{2}(z-t)^2\right] dz \quad (5.6.10)$$

In the integral, if we use the simple substitution $u = z - t$ then the integral becomes $\int_{-\infty}^{\infty} \phi(u) du = 1$. Hence

$$\mathbb{E}(e^{tZ}) = e^{\frac{1}{2}t^2},$$

2. This follows from (a) since $\chi(t) = m(it)$.

Thus, the standard normal distribution has the curious property that the characteristic function is a multiple of the probability density function:

$$\chi = \sqrt{2\pi}\phi \quad (5.6.11)$$

The moment generating function can be used to give another derivation of the moments of Z , since we know that $\mathbb{E}(Z^n) = m^{(n)}(0)$.

The General Normal Distribution

The general normal distribution is the location-scale family associated with the standard normal distribution.

Suppose that $\mu \in \mathbb{R}$ and $\sigma \in (0, \infty)$ and that Z has the standard normal distribution. Then $X = \mu + \sigma Z$ has the *normal distribution* with location parameter μ and scale parameter σ .

Distribution Functions

Suppose that X has the normal distribution with location parameter $\mu \in \mathbb{R}$ and scale parameter $\sigma \in (0, \infty)$. The basic properties of the density function and distribution function of X follow from general results for location scale families.

The probability density function f of X is given by

$$f(x) = \frac{1}{\sigma} \phi\left(\frac{x-\mu}{\sigma}\right) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right], \quad x \in \mathbb{R} \quad (5.6.12)$$

Proof

This follows from the change of variables formula corresponding to the transformation $x = \mu + \sigma z$.

The probability density function f satisfies the following properties:

1. f is symmetric about $x = \mu$.
2. f increases and then decreases with mode $x = \mu$.
3. f is concave upward then downward then upward again, with inflection points at $x = \mu \pm \sigma$.
4. $f(x) \rightarrow 0$ as $x \rightarrow \infty$ and as $x \rightarrow -\infty$.

Proof

These properties follow from the corresponding [properties of \$\phi\$](#) .

In the special distribution simulator, select the normal distribution. Vary the parameters and note the shape and location of the probability density function. With your choice of parameter settings, run the simulation 1000 times and compare the empirical density function to the true probability density function.

Let F denote the distribution function of X , and as above, let Φ denote the standard normal distribution function.

The distribution function F and quantile function F^{-1} satisfy the following properties:

1. $F(x) = \Phi\left(\frac{x-\mu}{\sigma}\right)$ for $x \in \mathbb{R}$.
2. $F^{-1}(p) = \mu + \sigma \Phi^{-1}(p)$ for $p \in (0, 1)$.
3. $F(\mu) = \frac{1}{2}$ so the median occurs at $x = \mu$.

Proof

Part (a) follows since $X = \mu + \sigma Z$. Parts (b) and (c) follow from (a).

In the special distribution calculator, select the normal distribution. Vary the parameters and note the shape of the density function and the distribution function.

Moments

Suppose again that X has the normal distribution with location parameter $\mu \in \mathbb{R}$ and scale parameter $\sigma \in (0, \infty)$. As the notation suggests, the location and scale parameters are also the mean and standard deviation, respectively.

The mean and variance of X are

1. $\mathbb{E}(X) = \mu$
2. $\text{var}(X) = \sigma^2$

Proof

This follows from the representation $X = \mu + \sigma Z$ and basic properties of expected value and variance.

So the parameters of the normal distribution are usually referred to as the *mean* and *standard deviation* rather than *location* and *scale*. The central moments of X can be computed easily from the moments of the standard normal distribution. The ordinary (raw) moments of X can be computed from the central moments, but the formulas are a bit messy.

For $n \in \mathbb{N}$,

1. $\mathbb{E}[(X - \mu)^{2n}] = 1 \cdot 3 \cdots (2n - 1)\sigma^{2n} = (2n)!\sigma^{2n} / (n!2^n)$
2. $\mathbb{E}[(X - \mu)^{2n+1}] = 0$

All of the odd central moments of X are 0, a fact that also follows from the symmetry of the probability density function.

In the special distribution simulator select the normal distribution. Vary the mean and standard deviation and note the size and location of the mean/standard deviation bar. With your choice of parameter settings, run the simulation 1000 times and compare the empirical mean and standard deviation to the true mean and standard deviation.

The following exercise gives the skewness and kurtosis.

The skewness and kurtosis of X are

1. $\text{skew}(X) = 0$
2. $\text{kurt}(X) = 3$

Proof

The skewness and kurtosis of a variable are defined in terms of the standard score, so these results follows from the [corresponding result for \$Z\$](#) .

The moment generating function M and characteristic function χ of X are given by

1. $M(t) = \exp(\mu t + \frac{1}{2}\sigma^2 t^2)$ for $t \in \mathbb{R}$.
2. $\chi(t) = \exp(i\mu t - \frac{1}{2}\sigma^2 t^2)$ for $t \in \mathbb{R}$

Proof

1. This follows from the representation $X = \mu + \sigma Z$, basic properties of expected value, and the MGF of Z in (12):

$$\mathbb{E}(e^{tX}) = \mathbb{E}(e^{t\mu + t\sigma Z}) = e^{t\mu} \mathbb{E}(e^{t\sigma Z}) = e^{t\mu} e^{\frac{1}{2}t^2\sigma^2} = e^{t\mu + \frac{1}{2}\sigma^2 t^2} \quad (5.6.13)$$

2. This follows from (a) since $\chi(t) = M(it)$.

Relations

The normal family of distributions satisfies two very important properties: invariance under linear transformations of the variable and invariance with respect to sums of independent variables. The first property is essentially a restatement of the fact that the normal distribution is a location-scale family.

Suppose that X is normally distributed with mean μ and variance σ^2 . If $a \in \mathbb{R}$ and $b \in \mathbb{R} \setminus \{0\}$, then $a + bX$ is normally distributed with mean $a + b\mu$ and variance $b^2\sigma^2$.

Proof

The MGF of $a + bX$ is

$$\mathbb{E} \left[e^{t(a+bX)} \right] = e^{ta} \mathbb{E} \left[e^{(tb)X} \right] = e^{ta} e^{\mu(tb) + \sigma^2(tb)^2/2} = e^{(a+b\mu)t + b^2\sigma^2 t^2/2} \quad (5.6.14)$$

which we recognize as the MGF of the normal distribution with mean $a + b\mu$ and variance $b^2\sigma^2$.

Recall that in general, if X is a random variable with mean μ and standard deviation $\sigma > 0$, then $Z = (X - \mu)/\sigma$ is the *standard score* of X . A corollary of the last result is that if X has a normal distribution then the standard score Z has a standard normal distribution. Conversely, any normally distributed variable can be constructed from a standard normal variable.

Standard score.

1. If X has the normal distribution with mean μ and standard deviation σ then $Z = \frac{X - \mu}{\sigma}$ has the standard normal distribution.
2. If Z has the standard normal distribution and if $\mu \in \mathbb{R}$ and $\sigma \in (0, \infty)$, then $X = \mu + \sigma Z$ has the normal distribution with mean μ and standard deviation σ .

Suppose that X_1 and X_2 are independent random variables, and that X_i is normally distributed with mean μ_i and variance σ_i^2 for $i \in \{1, 2\}$. Then $X_1 + X_2$ is normally distributed with

1. $\mathbb{E}(X_1 + X_2) = \mu_1 + \mu_2$
2. $\text{var}(X_1 + X_2) = \sigma_1^2 + \sigma_2^2$

Proof

The MGF of $X_1 + X_2$ is the product of the MGFs, so

$$\mathbb{E}(\exp[t(X_1 + X_2)]) = \exp(\mu_1 t + \sigma_1^2 t^2/2) \exp(\mu_2 t + \sigma_2^2 t^2/2) = \exp[(\mu_1 + \mu_2)t + (\sigma_1^2 + \sigma_2^2)t^2/2] \quad (5.6.15)$$

which we recognize as the MGF of the normal distribution with mean $\mu_1 + \mu_2$ and variance $\sigma_1^2 + \sigma_2^2$.

This theorem generalizes to a sum of n independent, normal variables. The important part is that the sum is still normal; the expressions for the mean and variance are standard results that hold for the sum of independent variables generally. As a consequence of this result and the one for [linear transformations](#), it follows that the normal distribution is stable.

The normal distribution is stable. Specifically, suppose that X has the normal distribution with mean $\mu \in \mathbb{R}$ and variance $\sigma^2 \in (0, \infty)$. If (X_1, X_2, \dots, X_n) are independent copies of X , then $X_1 + X_2 + \dots + X_n$ has the same distribution as $(n - \sqrt{n})\mu + \sqrt{n}X$, namely normal with mean $n\mu$ and variance $n\sigma^2$.

Proof

As a consequence of the result for [sums](#) $X_1 + X_2 + \dots + X_n$ has the normal distribution with mean $n\mu$ and variance $n\sigma^2$. As a consequence of the result for [linear transformations](#), $(n - \sqrt{n})\mu + \sqrt{n}X$ has the normal distribution with mean $(n - \sqrt{n})\mu + \sqrt{n}\mu = n\mu$ and variance $(\sqrt{n})^2\sigma^2 = n\sigma^2$.

All stable distributions are infinitely divisible, so the normal distribution belongs to this family as well. For completeness, here is the explicit statement:

The normal distribution is infinitely divisible. Specifically, if X has the normal distribution with mean $\mu \in \mathbb{R}$ and variance $\sigma^2 \in (0, \infty)$, then for $n \in \mathbb{N}_+$, X has the same distribution as $X_1 + X_2 + \dots + X_n$ where (X_1, X_2, \dots, X_n) are independent, and each has the normal distribution with mean μ/n and variance σ^2/n .

Finally, the normal distribution belongs to the family of general exponential distributions.

Suppose that X has the normal distribution with mean μ and variance σ^2 . The distribution is a two-parameter exponential family with natural parameters $\left(\frac{\mu}{\sigma^2}, -\frac{1}{2\sigma^2}\right)$, and natural statistics (X, X^2) .

Proof

Expanding the square, the normal PDF can be written in the form

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{\mu^2}{2\sigma^2}\right) \exp\left(\frac{\mu}{\sigma^2}x - \frac{1}{2\sigma^2}x^2\right), \quad x \in \mathbb{R} \quad (5.6.16)$$

so the result follows from the definition of the general exponential family.

A number of other special distributions studied in this chapter are constructed from normally distributed variables. These include

- The lognormal distribution
- The folded normal distribution, which includes the half normal distribution as a special case
- The Rayleigh distribution
- The Maxwell distribution
- The Lévy distribution

Also, as mentioned at the beginning of this section, the importance of the normal distribution stems in large part from the central limit theorem, one of the fundamental theorems of probability. By virtue of this theorem, the normal distribution is connected to many other distributions, by means of limits and approximations, including the special distributions in the following list. Details are given in the individual sections.

- The binomial distribution
- The negative binomial distribution
- The Poisson distribution
- The gamma distribution
- The chi-square distribution
- The student t distribution
- The Irwin-Hall distribution

Computational Exercises

Suppose that the volume of beer in a bottle of a certain brand is normally distributed with mean 0.5 liter and standard deviation 0.01 liter.

1. Find the probability that a bottle will contain at least 0.48 liter.
2. Find the volume that corresponds to the 95th percentile

Answer

Let X denote the volume of beer in liters

1. $\mathbb{P}(X > 0.48) = 0.9772$
2. $x_{0.95} = 0.51645$

A metal rod is designed to fit into a circular hole on a certain assembly. The radius of the rod is normally distributed with mean 1 cm and standard deviation 0.002 cm. The radius of the hole is normally distributed with mean 1.01 cm and standard deviation 0.003 cm. The machining processes that produce the rod and the hole are independent. Find the probability that the rod is too big for the hole.

Answer

Let X denote the radius of the rod and Y the radius of the hole. $\mathbb{P}(Y - X < 0) = 0.0028$

The weight of a peach from a certain orchard is normally distributed with mean 8 ounces and standard deviation 1 ounce. Find the probability that the combined weight of 5 peaches exceeds 45 ounces.

Answer

Let X denote the combined weight of the 5 peaches, in ounces. $\mathbb{P}(X > 45) = 0.0127$

A Further Generalization

In some settings, it's convenient to consider a constant as having a normal distribution (with mean being the constant and variance 0, of course). This convention simplifies the statements of theorems and definitions in these settings. Of course, the formulas for

the [probability density function](#) and the [distribution function](#) do not hold for a constant, but the other results involving the [moment generating function](#), [linear transformations](#), and [sums](#) are still valid. Moreover, the result for [linear transformations](#) would hold for all a and b .

This page titled [5.6: The Normal Distribution](#) is shared under a [CC BY 2.0](#) license and was authored, remixed, and/or curated by [Kyle Siegrist](#) ([Random Services](#)) via [source content](#) that was edited to the style and standards of the LibreTexts platform.

5.7: The Multivariate Normal Distribution

The multivariate normal distribution is among the most important of multivariate distributions, particularly in statistical inference and the study of Gaussian processes such as Brownian motion. The distribution arises naturally from linear transformations of independent normal variables. In this section, we consider the bivariate normal distribution first, because explicit results can be given and because graphical interpretations are possible. Then, with the aid of matrix notation, we discuss the general multivariate distribution.

The Bivariate Normal Distribution

The Standard Distribution

Recall that the probability density function ϕ of the standard normal distribution is given by

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}, \quad z \in \mathbb{R} \quad (5.7.1)$$

The corresponding distribution function is denoted Φ and is considered a special function in mathematics:

$$\Phi(z) = \int_{-\infty}^z \phi(x) dx = \int_{-\infty}^z \frac{1}{\sqrt{2\pi}} e^{-x^2/2} dx, \quad z \in \mathbb{R} \quad (5.7.2)$$

Finally, the moment generating function m is given by

$$m(t) = \mathbb{E}(e^{tZ}) = \exp\left[\frac{1}{2}\text{var}(tZ)\right] = e^{t^2/2}, \quad t \in \mathbb{R} \quad (5.7.3)$$

Suppose that Z and W are independent random variables, each with the standard normal distribution. The distribution of (Z, W) is known as the *standard bivariate normal distribution*.

The basic properties of the standard bivariate normal distribution follow easily from independence and properties of the (univariate) normal distribution. Recall first that the graph of a function $f: \mathbb{R}^2 \rightarrow \mathbb{R}$ is a surface. For $c \in \mathbb{R}$, the set of points $\{(x, y) \in \mathbb{R}^2 : f(x, y) = c\}$ is the *level curve* of f at level c . The graph of f can be understood by means of the level curves.

The probability density function ϕ_2 of the standard bivariate normal distribution is given by

$$\phi_2(z, w) = \frac{1}{2\pi} e^{-\frac{1}{2}(z^2 + w^2)}, \quad (z, w) \in \mathbb{R}^2 \quad (5.7.4)$$

1. The level curves of ϕ_2 are circles centered at the origin.
2. The mode of the distribution is $(0, 0)$.
3. ϕ_2 is concave downward on $\{(z, w) \in \mathbb{R}^2 : z^2 + w^2 < 1\}$

Proof

By independence, $\phi_2(z, w) = \phi(z)\phi(w)$ for $(z, w) \in \mathbb{R}^2$. Parts (a) and (b) are clear. For part (c), the second derivative matrix of ϕ_2 is

$$\begin{bmatrix} \phi_2(z, w)(z^2 - 1) & \phi_2(z, w)zw \\ \phi_2(z, w)zw & \phi_2(z, w)(w^2 - 1) \end{bmatrix} \quad (5.7.5)$$

with determinant $\phi_2^2(z, w)(1 - z^2 - w^2)$. The determinant is positive and the diagonal entries negative on the circular region $\{(z, w) \in \mathbb{R}^2 : z^2 + w^2 < 1\}$, so the matrix is negative definite on this region.

Clearly ϕ has a number of symmetry properties as well: $\phi_2(z, w)$ is symmetric in z about 0 so that $\phi_2(-z, w) = \phi_2(z, w)$; $\phi_2(z, w)$ is symmetric in w about 0 so that $\phi_2(z, -w) = \phi_2(z, w)$; $\phi_2(z, w)$ is symmetric in (z, w) so that $\phi_2(z, w) = \phi_2(w, z)$. In short, ϕ_2 has the classical “bell shape” that we associate with normal distributions.

Open the bivariate normal experiment, keep the default settings to get the standard bivariate normal distribution. Run the experiment 1000 times. Observe the cloud of points in the scatterplot, and compare the empirical density functions to the probability density functions.

Suppose that (Z, W) has the standard bivariate normal distribution. The moment generating function m_2 of (Z, W) is given by

$$m_2(s, t) = \mathbb{E}[\exp(sZ + tW)] = \exp\left[\frac{1}{2}\text{var}(sZ + tW)\right] = \exp\left[\frac{1}{2}(s^2 + t^2)\right], \quad (s, t) \in \mathbb{R}^2 \quad (5.7.6)$$

Proof

By independence, $m_2(s, t) = m(s)m(t)$ for $(s, t) \in \mathbb{R}^2$ where m is the standard normal MGF.

The General Distribution

The general bivariate normal distribution can be constructed by means of an affine transformation on a standard bivariate normal vector. The distribution has 5 parameters. As we will see, two are location parameters, two are scale parameters, and one is a correlation parameter.

Suppose that (Z, W) has the standard bivariate normal distribution. Let $\mu, \nu \in \mathbb{R}$; $\sigma, \tau \in (0, \infty)$; and $\rho \in (-1, 1)$, and let X and Y be new random variables defined by

$$X = \mu + \sigma Z \quad (5.7.7)$$

$$Y = \nu + \tau \rho Z + \tau \sqrt{1 - \rho^2} W \quad (5.7.8)$$

The joint distribution of (X, Y) is called the *bivariate normal distribution* with parameters $(\mu, \nu, \sigma, \tau, \rho)$

We can use the change of variables formula to find the joint probability density function.

Suppose that (X, Y) has the bivariate normal distribution with the parameters $(\mu, \nu, \sigma, \tau, \rho)$ as specified above. The joint probability density function f of (X, Y) is given by

$$f(x, y) = \frac{1}{2\pi\sigma\tau\sqrt{1-\rho^2}} \exp\left\{-\frac{1}{2(1-\rho^2)}\left[\frac{(x-\mu)^2}{\sigma^2} - 2\rho\frac{(x-\mu)(y-\nu)}{\sigma\tau} + \frac{(y-\nu)^2}{\tau^2}\right]\right\}, \quad (x, y) \in \mathbb{R}^2 \quad (5.7.9)$$

1. The level curves of f are ellipses centered at (μ, ν) .
2. The mode of the distribution is (μ, ν) .

Proof

Consider the transformation that defines (x, y) from (z, w) in the [definition](#). The inverse transformation is given by

$$z = \frac{x - \mu}{\sigma} \quad (5.7.10)$$

$$w = \frac{x - \mu}{\sigma\sqrt{1-\rho^2}} - \rho\frac{y - \nu}{\tau\sqrt{1-\rho^2}} \quad (5.7.11)$$

The Jacobian of the inverse transformation is

$$\frac{\partial(z, w)}{\partial(x, y)} = \frac{1}{\sigma\tau\sqrt{1-\rho^2}} \quad (5.7.12)$$

Note that the Jacobian is a constant, because the transformation is affine. The result now follows from the independence of Z and W , and the change of variables formula

1. Note that f has the form $f(x, y) = a \exp[-bg(x, y)]$ where a and b are positive constants and

$$g(x, y) = \frac{(x - \mu)^2}{\sigma^2} - 2\rho\frac{(x - \mu)(y - \nu)}{\sigma\tau} + \frac{(y - \nu)^2}{\tau^2}, \quad (x, y) \in \mathbb{R}^2 \quad (5.7.13)$$

The graph of g is a paraboloid opening upward. The level curves of f are the same as the level curves of g (but at different levels of course).

2. The maximum of f occurs at the minimum of g , at the point (μ, ν) .

The following theorem gives fundamental properties of the bivariate normal distribution.

Suppose that (X, Y) has the bivariate normal distribution with parameters $(\mu, \nu, \sigma, \tau, \rho)$ as specified above. Then

1. X is normally distributed with mean μ and standard deviation σ .
2. Y is normally distributed with mean ν and standard deviation τ .
3. $\text{cor}(X, Y) = \rho$.
4. X and Y are independent if and only if $\rho = 0$.

Proof

These result can be proved from the probability density function, but it's easier and more helpful to use the transformation definition. So, assume that (X, Y) is defined in terms of the standard bivariate normal pair (Z, W) as in the [definition](#).

1. $X = \mu + \sigma Z$ so X has the normal distribution with mean μ and standard deviation σ . This is a basic property of the normal distribution, and indeed is the way that the general normal variable is constructed from a standard normal variable.

2. Since Z and W are independent and each has the standard normal distribution, $Y = \nu + \tau\rho Z + \tau\sqrt{1-\rho^2}W$ is normally distributed by another basic property. Because Z and W have mean 0, it follows from the linear property of expected value that $\mathbb{E}(Y) = \nu$. Similarly, since Z and W have variance 1, it follows from basic properties of variance that $\text{var}(Y) = \tau^2\rho^2 + \tau^2(1-\rho^2) = \tau^2$.
3. Using the bi-linear property of covariance and independence we have $\text{cov}(X, Y) = \rho\tau\sigma \text{cov}(Z, Z) = \rho\tau\sigma$, and hence from (a) and (b), $\text{cor}(X, Y) = \rho$.
4. As a general property, recall that if X and Y are independent then $\text{cor}(X, Y) = 0$. Conversely, if $\rho = 0$ then $X = \mu + \sigma Z$ and $Y = \nu + \tau W$. Since Z and W are independent, so are X and Y .

Thus, two random variables with a joint normal distribution are independent if and only if they are uncorrelated.

In the bivariate normal experiment, change the standard deviations of X and Y with the scroll bars. Watch the change in the shape of the probability density functions. Now change the correlation with the scroll bar and note that the probability density functions do *not* change. For various values of the parameters, run the experiment 1000 times. Observe the cloud of points in the scatterplot, and compare the empirical density functions to the probability density functions.

In the case of perfect correlation ($\rho = 1$ or $\rho = -1$), the distribution of (X, Y) is also said to be bivariate normal, but *degenerate*. In this case, we know from our study of covariance and correlation that (X, Y) takes values on the regression line $\{(x, y) \in \mathbb{R}^2 : y = \nu + \rho\frac{\tau}{\sigma}(x - \mu)\}$, and hence does not have a probability density function (with respect to Lebesgue measure on \mathbb{R}^2). Degenerate normal distributions will be discussed in more detail [below](#).

In the bivariate normal experiment, run the experiment 1000 times with the values of ρ given below and selected values of σ and τ . Observe the cloud of points in the scatterplot and compare the empirical density functions to the probability density functions.

1. $\rho \in \{0, 0.3, 0.5, 0.7, 1\}$
2. $\rho \in \{-0.3, -0.5, -0.7, -1\}$

The conditional distributions are also normal.

Suppose that (X, Y) has the bivariate normal distribution with parameters $(\mu, \nu, \sigma, \tau, \rho)$ as specified above.

1. For $x \in \mathbb{R}$, the conditional distribution of Y given $X = x$ is normal with mean $\mathbb{E}(Y | X = x) = \nu + \rho\frac{\tau}{\sigma}(x - \mu)$ and variance $\text{var}(Y | X = x) = \tau^2(1 - \rho^2)$.
2. For $y \in \mathbb{R}$, the conditional distribution of X given $Y = y$ is normal with mean $\mathbb{E}(X | Y = y) = \mu + \rho\frac{\sigma}{\tau}(y - \nu)$ and variance $\text{var}(X | Y = y) = \sigma^2(1 - \rho^2)$.

Proof from density functions

By symmetry, we need only prove (a). The conditional PDF of Y given $X = x$ is $y \mapsto f(x, y)/g(x)$ where f is the [joint PDF](#), and where g is the PDF of X , namely the normal PDF with mean μ and standard deviation σ . The result then follows after some algebra.

Proof from random variables

Again, we only need to prove (a). We can assume that (X, Y) is defined in terms of a standard normal pair (Z, W) as in the [definition](#). Hence

$$Y = \nu + \rho\tau\frac{X - \mu}{\sigma} + \tau\sqrt{1 - \rho^2}W \quad (5.7.14)$$

Since that X and W are independent, the conditional distribution of Y given $X = x$ is the distribution of $\nu + \rho\tau\frac{x - \mu}{\sigma} + \tau\sqrt{1 - \rho^2}W$. The latter distribution is normal, with mean and variance specified in the theorem.

Note that the conditional variances do not depend on the value of the given variable.

In the bivariate normal experiment, set the standard deviation of X to 1.5, the standard deviation of Y to 0.5, and the correlation to 0.7.

1. Run the experiment 100 times.
2. For each run, compute $\mathbb{E}(Y | X = x)$ the predicted value of Y for the given the value of X .
3. Over all 100 runs, compute the square root of the average of the squared errors between the predicted value of Y and the true value of Y .

You may be perplexed by the lack of symmetry in how (X, Y) is defined in terms of (Z, W) in the original [definition](#). Note however that the distribution is completely determined by the 5 parameters. If we define $X' = \mu + \sigma\rho Z + \sigma\sqrt{1 - \rho^2}W$ and $Y' = \nu + \tau Z$ then (X', Y') has the same distribution as (X, Y) , namely the bivariate normal distribution with parameters $(\mu, \nu, \sigma, \tau, \rho)$ (although, of course (X', Y') and (X, Y) are different random vectors). There are other ways to define the same distribution as an affine transformation of (Z, W) —the situation will be clarified in the next subsection.

Suppose that (X, Y) has the bivariate normal distribution with parameters $(\mu, \nu, \sigma, \tau, \rho)$. Then (X, Y) has moment generating function M given by

$$M(s, t) = \mathbb{E}[\exp(sX + tY)] = \exp\left[\mathbb{E}(sX + tY) + \frac{1}{2}\text{var}(sX + tY)\right] = \exp\left[\mu s + \nu t + \frac{1}{2}(\sigma^2 s^2 + 2\rho\sigma\tau st + \tau^2 t^2)\right], \quad (s, t) \in \mathbb{R}^2 \quad (5.7.15)$$

Proof

Using the representation of (X, Y) in terms of the standard bivariate normal vector (Z, W) in the [definition](#) and collecting terms gives

$$M(s, t) = \mathbb{E}\left(\exp\left[(\mu s + \nu t) + (\sigma s + \rho\tau t)Z + \tau\sqrt{1 - \rho^2}tW\right]\right) \quad (5.7.16)$$

Hence from independence we have

$$M(s, t) = \exp(\mu s + \nu t)m(\sigma s + \rho\tau t)m\left(\tau\sqrt{1 - \rho^2}t\right) \quad (5.7.17)$$

where m is the standard normal MGF. Substituting and simplifying gives the result.

We showed [above](#) that if (X, Y) has a bivariate normal distribution then the marginal distributions of X and Y are also normal. The converse is not true.

Suppose that (X, Y) has probability density function f given by

$$f(x, y) = \frac{1}{2\pi}e^{-(x^2+y^2)/2}\left[1 + xy e^{-(x^2+y^2-2)/2}\right], \quad (x, y) \in \mathbb{R}^2 \quad (5.7.18)$$

1. X and Y each have standard normal distributions.
2. (X, Y) does not have a bivariate normal distribution.

Proof

Note that $f(x, y) = \phi_2(x, y)[1 + u(x)u(y)]$ for $(x, y) \in \mathbb{R}^2$, where ϕ_2 is the [bivariate standard normal PDF](#) and where u is given by $u(t) = te^{-(t^2-1)/2}$ for $t \in \mathbb{R}$. From simple calculus, u is symmetric about 0, has a local maximum at $t = 1$, and $u(t) \rightarrow 0$ as $t \rightarrow \infty$. In particular, $|u(t)| \leq 1$ for $t \in \mathbb{R}$ and hence $f(x, y) \geq 0$ for $(x, y) \in \mathbb{R}^2$. Next, a helpful trick is that we can write integrals of f as expected values of functions of a standard normal pair (Z, W) . In particular,

$$\int_{\mathbb{R}^2} f(x, y)dx dy = \mathbb{E}[1 + u(Z)u(W)] = 1 + \mathbb{E}[u(Z)]\mathbb{E}[u(W)] = 1 \quad (5.7.19)$$

since $\mathbb{E}[u(Z)] = \mathbb{E}[u(W)] = 0$ by the symmetry of the standard normal distribution and the symmetry of u about 0. Hence f is a valid PDF on \mathbb{R}^2 . Suppose now that (X, Y) has PDF f .

1. The PDF of X at $x \in \mathbb{R}$ is

$$\int_{\mathbb{R}} f(x, y)dy = \int_{\mathbb{R}} \phi_2(x, y)dy + u(x)\mathbb{E}[u(W)] = \phi(x) \quad (5.7.20)$$

where as usual, ϕ is the standard normal PDF on \mathbb{R} . By symmetry, Y also has the standard normal distribution.

2. f does not have the form of a [bivariate normal PDF](#) and hence (X, Y) does not have a bivariate normal distribution.

Transformations

Like its univariate counterpart, the family of bivariate normal distributions is preserved under two types of transformations on the underlying random vector: affine transformations and sums of independent vectors. We start with a preliminary result on affine transformations that should help clarify the original [definition](#). Throughout this discussion, we assume that the parameter vector $(\mu, \nu, \sigma, \tau, \rho)$ satisfies the usual conditions: $\mu, \nu \in \mathbb{R}$, and $\sigma, \tau \in (0, \infty)$, and $\rho \in (-1, 1)$.

Suppose that (Z, W) has the standard bivariate normal distribution. Let $X = a_1 + b_1Z + c_1W$ and $Y = a_2 + b_2Z + c_2W$ where the coefficients are in \mathbb{R} and $b_1c_2 - c_1b_2 \neq 0$. Then (X, Y) has a bivariate normal distribution with parameters given by

1. $\mathbb{E}(X) = a_1$
2. $\mathbb{E}(Y) = a_2$
3. $\text{var}(X) = b_1^2 + c_1^2$
4. $\text{var}(Y) = b_2^2 + c_2^2$
5. $\text{cov}(X, Y) = b_1b_2 + c_1c_2$

Proof

A direct proof using the change of variables formula is possible, but our goal is to show that (X, Y) can be written in the form given above in the [definition](#). First, parts (a)–(e) follow from basic properties of expected value, variance, and covariance. So, in the notation used in the definition, we have $\mu = a_1$, $\nu = a_2$, $\sigma = \sqrt{b_1^2 + c_1^2}$, $\tau = \sqrt{b_2^2 + c_2^2}$, and

$$\rho = \frac{b_1 b_2 + c_1 c_2}{\sqrt{b_1^2 + c_1^2} \sqrt{b_2^2 + c_2^2}} \quad (5.7.21)$$

(Note from the assumption on the coefficients that $b_1^2 + c_1^2 > 0$ and $b_2^2 + c_2^2 > 0$). Simple algebra shows that

$$\sqrt{1 - \rho^2} = \frac{b_1 c_2 - c_1 b_2}{\sqrt{b_1^2 + c_1^2} \sqrt{b_2^2 + c_2^2}} \quad (5.7.22)$$

Next we define

$$U = \frac{b_1 Z + c_1 W}{\sqrt{b_1^2 + c_1^2}} \quad (5.7.23)$$

$$V = \frac{c_1 Z - b_1 W}{\sqrt{b_1^2 + c_1^2}} \quad (5.7.24)$$

The transformation that defines (u, v) from (z, w) is its own inverse, and has Jacobian 1. Hence it follows that (U, V) has the same joint distribution as (Z, W) , namely the standard bivariate normal distribution. Simple algebra shows that

$$X = a_1 + \sqrt{b_1^2 + c_1^2} U = \mu + \sigma U \quad (5.7.25)$$

$$Y = a_2 + \frac{b_1 b_2 + c_1 c_2}{\sqrt{b_1^2 + c_1^2}} U + \frac{c_1 b_2 - b_1 c_2}{\sqrt{b_1^2 + c_1^2}} V = \nu + \tau \rho U + \tau \sqrt{1 - \rho^2} V \quad (5.7.26)$$

This is the form given in the [definition](#), so it follows that (X, Y) has a bivariate normal distribution.

Now it is easy to show more generally that the bivariate normal distribution is closed with respect to affine transformations.

Suppose that (X, Y) has the bivariate normal distribution with parameters $(\mu, \nu, \sigma, \tau, \rho)$. Define $U = a_1 + b_1 X + c_1 Y$ and $V = a_2 + b_2 X + c_2 Y$, where the coefficients are in \mathbb{R} and $b_1 c_2 - c_1 b_2 \neq 0$. Then (U, V) has a bivariate normal distribution with parameters as follows:

1. $\mathbb{E}(U) = a_1 + b_1 \mu + c_1 \nu$
2. $\mathbb{E}(V) = a_2 + b_2 \mu + c_2 \nu$
3. $\text{var}(U) = b_1^2 \sigma^2 + c_1^2 \tau^2 + 2b_1 c_1 \rho \sigma \tau$
4. $\text{var}(V) = b_2^2 \sigma^2 + c_2^2 \tau^2 + 2b_2 c_2 \rho \sigma \tau$
5. $\text{cov}(U, V) = b_1 b_2 \sigma^2 + c_1 c_2 \tau^2 + (b_1 c_2 + b_2 c_1) \rho \sigma \tau$

Proof

From our original [construction](#), we can write $X = \mu + \sigma Z$ and $Y = \nu + \tau \rho Z + \tau \sqrt{1 - \rho^2} W$ where (Z, W) has the standard bivariate normal distribution. Then by simple substitution, $U = A_1 + B_1 Z + C_1 W$ and $V = A_2 + B_2 Z + C_2 W$ where $A_i = a_i + b_i \mu + c_i \nu$, $B_i = b_i \sigma + c_i \tau \rho$, $C_i = c_i \tau \sqrt{1 - \rho^2}$ for $i \in \{1, 2\}$. By simple algebra,

$$B_1 C_2 - C_1 B_2 = \sigma \tau \sqrt{1 - \rho^2} (b_1 c_2 - c_1 b_2) \neq 0 \quad (5.7.27)$$

Hence (U, V) has a bivariate normal distribution from the previous theorem. Parts (a)–(e) follow from basic properties of expected value, variance, and covariance.

The bivariate normal distribution is preserved with respect to sums of independent variables.
