

12.2: An Illustrative Data Set

Suppose you've become involved in a clinical trial in which you are testing a new antidepressant drug called *Joyzepam*. In order to construct a fair test of the drug's effectiveness, the study involves three separate drugs to be administered. One is a placebo, and the other is an existing antidepressant / anti-anxiety drug called *Anxifree*. A collection of 18 participants with moderate to severe depression are recruited for your initial testing. Because the drugs are sometimes administered in conjunction with psychological therapy, your study includes 9 people undergoing cognitive behavioural therapy (CBT) and 9 who are not. Participants are randomly assigned (doubly blinded, of course) a treatment, such that there are 3 CBT people and 3 no-therapy people assigned to each of the 3 drugs. A psychologist assesses the mood of each person after a 3 month run with each drug: and the overall improvement in each person's mood is assessed on a scale ranging from -5 to +5.

With that as the study design, let's now look at what we've got in the data file:

```
load( "../rbook-master/data/clinicaltrial.Rdata" ) # load data
str(clin.trial)
```

```
## 'data.frame':   18 obs. of  3 variables:
## $ drug      : Factor w/ 3 levels "placebo","anxifree",...: 1 1 1 2 2 2 3 3 3 1 ...
## $ therapy   : Factor w/ 2 levels "no.therapy","CBT": 1 1 1 1 1 1 1 1 1 2 ...
## $ mood.gain: num  0.5 0.3 0.1 0.6 0.4 0.2 1.4 1.7 1.3 0.6 ...
```

So we have a single data frame called `clin.trial`, containing three variables; `drug`, `therapy` and `mood.gain`. Next, let's print the data frame to get a sense of what the data actually look like.

```
print( clin.trial )
```

```
##      drug      therapy mood.gain
## 1 placebo no.therapy    0.5
## 2 placebo no.therapy    0.3
## 3 placebo no.therapy    0.1
## 4 anxifree no.therapy    0.6
## 5 anxifree no.therapy    0.4
## 6 anxifree no.therapy    0.2
## 7 joyzepam no.therapy    1.4
## 8 joyzepam no.therapy    1.7
## 9 joyzepam no.therapy    1.3
## 10 placebo      CBT     0.6
## 11 placebo      CBT     0.9
## 12 placebo      CBT     0.3
## 13 anxifree      CBT     1.1
## 14 anxifree      CBT     0.8
## 15 anxifree      CBT     1.2
## 16 joyzepam      CBT     1.8
## 17 joyzepam      CBT     1.3
## 18 joyzepam      CBT     1.4
```

For the purposes of this chapter, what we're really interested in is the effect of `drug` on `mood.gain`. The first thing to do is calculate some descriptive statistics and draw some graphs. In Chapter 5 we discussed a variety of different functions that can be used for this purpose. For instance, we can use the `xtabs()` function to see how many people we have in each group:

```
xtabs( ~drug, clin.trial )
```

```
## drug
## placebo anxifree joyzepam
##      6      6      6
```

Similarly, we can use the `aggregate()` function to calculate means and standard deviations for the `mood.gain` variable broken down by which `drug` was administered:

```
aggregate( mood.gain ~ drug, clin.trial, mean )
```

```
##      drug mood.gain
## 1 placebo 0.4500000
## 2 anxifree 0.7166667
## 3 joyzepam 1.4833333
```

```
aggregate( mood.gain ~ drug, clin.trial, sd )
```

```
##      drug mood.gain
## 1 placebo 0.2810694
## 2 anxifree 0.3920034
## 3 joyzepam 0.2136976
```

Finally, we can use `plotmeans()` from the `gplots` package to produce a pretty picture.

```
library(gplots)
plotmeans( formula = mood.gain ~ drug, # plot mood.gain by drug
            data = clin.trial,         # the data frame
            xlab = "Drug Administered", # x-axis label
            ylab = "Mood Gain",         # y-axis label
            n.label = FALSE,            # don't display sample size
            )
```

The results are shown in Figure 14.1, which plots the average mood gain for all three conditions; error bars show 95% confidence intervals. As the plot makes clear, there is a larger improvement in mood for participants in the Joyzepam group than for either the Anxifree group or the placebo group. The Anxifree group shows a larger mood gain than the control group, but the difference isn't as large.

The question that we want to answer is: are these difference “real”, or are they just due to chance?

```
## Warning: package 'gplots' was built under R version 3.5.2
```

```
##
## Attaching package: 'gplots'
```

```
## The following object is masked from 'package:stats':
##
##      lowess
```

Figure 14.1: Average mood gain as a function of drug administered. Error bars depict 95% confidence intervals associated with each of the group means.
