

11.2: Chi-Square One-Sample Goodness-of-Fit Tests

Learning Objectives

- To understand how to use a chi-square test to judge whether a sample fits a particular population well.

Suppose we wish to determine if an ordinary-looking six-sided die is fair, or balanced, meaning that every face has probability $1/6$ of landing on top when the die is tossed. We could toss the die dozens, maybe hundreds, of times and compare the actual number of times each face landed on top to the expected number, which would be $1/6$ of the total number of tosses. We wouldn't expect each number to be exactly $1/6$ of the total, but it should be close. To be specific, suppose the die is tossed $n = 60$ times with the results summarized in Table 11.2.1. For ease of reference we add a column of expected frequencies, which in this simple example is simply a column of 10s. The result is shown as Table 11.2.2. In analogy with the previous section we call this an "updated" table. A measure of how much the data deviate from what we would expect to see if the die really were fair is the sum of the squares of the differences between the observed frequency O and the expected frequency E in each row, or, standardizing by dividing each square by the expected number, the sum

$$\frac{\sum(O - E)^2}{E}$$

If we formulate the investigation as a test of hypotheses, the test is

H_0 : The die is fair

vs.

H_a : The die is not fair

Table 11.2.1: Die Contingency Table

Die Value	Assumed Distribution	Observed Frequency
1	$1/6$	9
2	$1/6$	15
3	$1/6$	9
4	$1/6$	8
5	$1/6$	6
6	$1/6$	13

Table 11.2.2: Updated Die Contingency Table

Die Value	Assumed Distribution	Observed Freq.	Expected Freq.
1	$1/6$	9	10
2	$1/6$	15	10
3	$1/6$	9	10
4	$1/6$	8	10
5	$1/6$	6	10
6	$1/6$	13	10

We would reject the null hypothesis that the die is fair only if the number $\frac{\sum(O - E)^2}{E}$ is large, so the test is right-tailed. In this example the random variable $\frac{\sum(O - E)^2}{E}$ has the chi-square distribution with five degrees of freedom. If we had decided at the

outset to test at the 10% level of significance, the critical value defining the rejection region would be, reading from Figure 7.1.6, $\chi^2_{\alpha} = \chi^2_{0.10} = 9.236$, so that the rejection region would be the interval

$$[9.236, \infty)$$

. When we compute the value of the standardized test statistic using the numbers in the last two columns of Table 11.2.2 we obtain

$$\begin{aligned} \sum \frac{(O-E)^2}{E} &= \frac{(-1)^2}{10} + \frac{(5)^2}{10} + \frac{(-1)^2}{10} + \frac{(-2)^2}{10} + \frac{(-4)^2}{10} + \frac{(3)^2}{10} \\ &= 0.1 + 2.5 + 0.1 + 0.4 + 1.6 + 0.9 \\ &= 5.6 \end{aligned}$$

Since $5.6 < 9.236$ the decision is not to reject H_0 . See Figure 11.2.1. The data do not provide sufficient evidence, at the 10% level of significance, to conclude that the die is loaded.

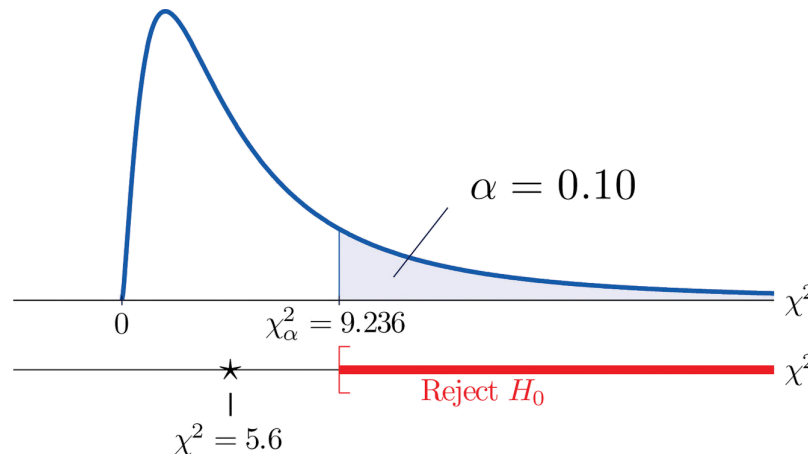

Figure 11.2.1: Balanced Die

In the general situation we consider a discrete random variable that can take I different values, x_1, x_2, \dots, x_I , for which the default assumption is that the probability distribution is

x	x_1	x_2	\dots	x_I
$P(x)$	p_1	p_2	\dots	p_I

We wish to test the hypotheses:

H_0 : The assumed probability distribution for X is valid
vs.

H_a : The assumed probability distribution for X is not valid

We take a sample of size n and obtain a list of observed frequencies. This is shown in Table 11.2.3. Based on the assumed probability distribution we also have a list of assumed frequencies, each of which is defined and computed by the formula

$$Ei = n \times pi$$

Table 11.2.3: General Contingency Table

Factor Levels	Assumed Distribution	Observed Frequency
1	p_1	O_1
2	p_2	O_2
\vdots	\vdots	\vdots
I	p_I	O_I

Table 11.2.3 is updated to Table 11.2.4 by adding the expected frequency for each value of X . To simplify the notation we drop indices for the observed and expected frequencies and represent Table 11.2.4 by Table 11.2.5

Table 11.2.4: Updated General Contingency Table

Factor Levels	Assumed Distribution	Observed Freq.	Expected Freq.
1	p_1	O_1	E_1
2	p_2	O_2	E_2
\vdots	\vdots	\vdots	\vdots
I	p_I	O_I	E_I

Table 11.2.5: Simplified Updated General Contingency Table

Factor Levels	Assumed Distribution	Observed Freq.	Expected Freq.
1	p_1	O	E
2	p_2	O	E
\vdots	\vdots	\vdots	\vdots
I	p_I	O	E

Here is the test statistic for the general hypothesis based on Table 11.2.5, together with the conditions that it follow a chi-square distribution.

✚ Test Statistic for Testing Goodness of Fit to a Discrete Probability Distribution

$$\chi^2 = \sum \frac{(O - E)^2}{E}$$

where the sum is over all the rows of the table (one for each value of X).

If

1. the true probability distribution of X is as assumed, and
2. the observed count O of each cell in Table 11.2.5 is at least 5,

then χ^2 approximately follows a chi-square distribution with $df = I - 1$ degrees of freedom.

The test is known as a goodness-of-fit χ^2 test since it tests the null hypothesis that the sample fits the assumed probability distribution well. It is always right-tailed, since deviation from the assumed probability distribution corresponds to large values of χ^2 .

Testing is done using either of the usual five-step procedures.

✓ Example 11.2.1

Table 11.2.6 shows the distribution of various ethnic groups in the population of a particular state based on a decennial U.S. census. Five years later a random sample of 2,500 residents of the state was taken, with the results given in Table 11.2.7 (along with the probability distribution from the census year). Test, at the 1% level of significance, whether there is sufficient evidence in the sample to conclude that the distribution of ethnic groups in this state five years after the census had changed from that in the census year.

Table 11.2.6: Ethnic Groups in the Census Year

Ethnicity	White	Black	Amer.-Indian	Hispanic	Asian	Others
Proportion	0.743	0.216	0.012	0.012	0.008	0.009

Table 11.2.7: Sample Data Five Years After the Census Year

--	--	--	--	--	--	--

Ethnicity	Assumed Distribution	Observed Frequency
White	0.743	1732
Black	0.216	538
American-Indian	0.012	32
Hispanic	0.012	42
Asian	0.008	133
Others	0.009	23

Solution

We test using the critical value approach.

- **Step 1.** The hypotheses of interest in this case can be expressed as

H_0 : The distribution of ethnic groups has not changed
vs.

H_a : The distribution of ethnic groups has changed

- **Step 2.** The distribution is chi-square.
- **Step 3.** To compute the value of the test statistic we must first compute the expected number for each row of Table 11.2.7. Since $n = 2500$, using the formula $E_i = n \times p_i$ and the values of p_i from either Table 11.2.6 or Table 11.2.7,

$$E_1 = 2500 \times 0.743 = 1857.5$$

$$E_2 = 2500 \times 0.216 = 540$$

$$E_3 = 2500 \times 0.012 = 30$$

$$E_4 = 2500 \times 0.012 = 30$$

$$E_5 = 2500 \times 0.008 = 20$$

$$E_6 = 2500 \times 0.009 = 22.5$$

Table 11.2.7 is updated to Table 11.2.8

Table 11.2.8: Observed and Expected Frequencies Five Years After the Census Year

Ethnicity	Assumed Dist.	Observed Freq.	Expected Freq.
White	0.743	1732	1857.5
Black	0.216	538	540
American-Indian	0.012	32	30
Hispanic	0.012	42	30
Asian	0.008	133	20
Others	0.009	23	22.5

The value of the test statistic is

$$\begin{aligned} \chi^2 &= \sum \frac{(O - E)^2}{E} \\ &= \frac{(1732 - 1857.5)^2}{1857.5} + \frac{(538 - 540)^2}{540} + \frac{(32 - 30)^2}{30} + \frac{(42 - 30)^2}{30} + \frac{(133 - 20)^2}{20} + \frac{(23 - 22.5)^2}{22.5} \\ &= 651.881 \end{aligned}$$

Since the random variable takes six values, $I = 6$. Thus the test statistic follows the chi-square distribution with $df = 6 - 1 = 5$ degrees of freedom.

Since the test is right-tailed, the critical value is $\chi^2_{0.01}$. Reading from Figure 7.1.6, $\chi^2_{0.01} = 15.086$, so the rejection region is $[15.086, \infty)$.

Since $651.881 > 15.086$ the decision is to reject the null hypothesis. See Figure 11.2.2 The data provide sufficient evidence, at the 1% level of significance, to conclude that the ethnic distribution in this state has changed in the five years since the U.S. census.

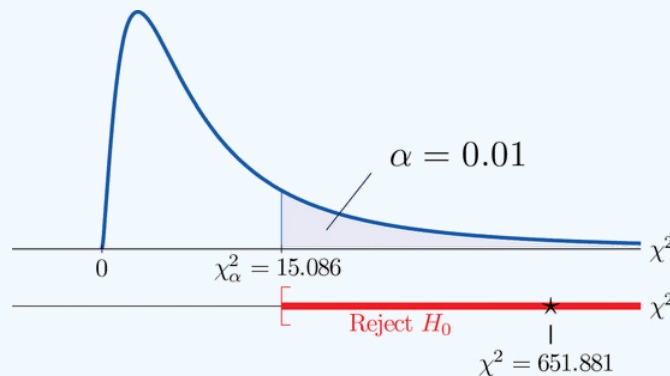

Figure 11.2.2: "Example 11.2.1"

Key Takeaway

- The chi-square goodness-of-fit test can be used to evaluate the hypothesis that a sample is taken from a population with an assumed specific probability distribution.
